
XlCalcNet Documentation

Release 0.9.0

Dietrich Hadler

October 18, 2026

Welcome to the documentation of **XlCalcNet**, an addin for MS E**x**ce**l** and LibreOffice **Calc**, based on Python**Net**. This edition of the documentation describes release 0.9.0.

XlCalcNet is free software released under the Mozilla Public License 2.0 (see *License*).

The git repository is https://github.com/duhadler/xlcalcnet)

This documentation is available online at https://duhadler.github.io/XlCalcNetDocsHTML/.

The pdf can be downloaded from https://github.com/duhadler/DocsXlCalcNet/raw/master/pdf/xlcalcnet.pdf.

PREFACE

Spreadheet formulas (as used in MS Excel and LibreOffice Calc) are probably the most widely used programming language in the world. In addition to the built-in formulas, there is also the option to write user-defined functions (UDFs) in the Basic dialects of these programs.

XlCalcNet extends these options by providing an additional set of functions which are accessible through the function dialog (MS Excel) or function wizard (LibreOffice Calc), and expect as first argument a string containing code written in Python. This code can call any function that is available in the underlying Python installation (currently supported are versions 3.8 - 3.15), which the user can populate with additional packages as needed.

Contents

Preface i

I Getting started 1

1 Setup and general usage 2

1.1 Setting up XlCalcNet . . . 3
1.1.1 Installing XlCalcNet . . . 3
1.1.2 Installing and using Python.NET: Calling C# from Python . . . 5
1.1.3 Installing and using the Tiny IDE as a Python application . . . 6
1.1.4 Installing and using Numpy, Matplotlib, Pandas, Scipy, Seaborn, Statsmodels and Scikit-learn . . . 20
1.1.5 Calling Python from C:#: socket server vs in-process calls . . . 34
1.1.6 Reasons for using multiprecision arithmetic . . . 39
1.1.7 Rebuilding the .dll files of XlCalcNet and XlCalcNet2 from source code . . . 41
1.2 Using XlCalcNet within MS Excel . . . 42
1.2.1 Preparing MS Excel for using XlCalcNet . . . 42
1.2.2 Using the Python standard library functions within spreadsheet formulas . . . 43
1.2.3 Using Numpy, Matplotlib, Pandas, Scipy, Seaborn and XlCalcNet within spreadsheet formulas . . . 45
1.2.4 Using dynamic arrrays in MS Excel . . . 51
1.2.5 Managing procedures instead of functions . . . 53
1.2.6 Uninstalling . . . 54
1.3 Using XlCalcNet within LibreOffice Calc . . . 55
1.3.1 Preparing LibreOffice Calc for using XlCalcNet . . . 55
1.3.2 Using the Python standard library functions within spreadsheet formulas . . . 55
1.3.3 Using Numpy, Matplotlib, Pandas, Scipy, Seaborn and XlCalcNet within spreadsheet formulas . . . 58
1.3.4 Using links to external `*.csv`, `*.xlsx` and `*.svg` files . . . 64
1.3.5 Managing procedures instead of functions . . . 71
1.3.6 Exporting and uninstalling . . . 72
1.4 General user interface and functions . . . 74
1.4.1 The Tiny Data Viewer . . . 74
1.4.2 The Output Monitor . . . 76
1.4.3 The Gallery of Plots . . . 78
1.4.4 Interactive 3D wpf plots . . . 83
1.4.5 Functions related to folders . . . 91
1.4.6 Information about installation status of supporting python packages . . . 92
1.4.7 Information about context lists, and setting global precision . . . 93
1.4.8 Support for running interactive Matplotlib output in a separate process . . . 94
1.5 Mathematical functions based on Mpmath, Gmpy2 and Python-Flint (only Python) . . . 95
1.5.1 Overview . . . 95
1.5.2 Double-precision arithmetic: `fpm` . . . 98
1.5.3 Binary floating-point with arbitrary-precision and exponent: `mpm` . . . 102
1.5.4 Interval arithmetic with arbitrary-precision and exponent:`ipm` . . . 106
1.5.5 Decimal floating-point in arbitrary-precision with limited exponent: `dpm` . . . 110

1.5.6 Rational numbers: qpm . . . 115
1.5.7 Binary floating-point in arbitrary-precision with limited exponent: gpm . . . 117
1.5.8 Binary balls in arbitrary-precision and with arbitrary exponent: apm . . . 122
1.5.9 Numpy support for multiprecision data types: npm . . . 126
1.6 Mathematical functions in fixed precision (C#, can be called from Python) . . . 127
1.6.1 C# based context groups . . . 127
1.6.2 Scalar functions with Double and Complex: math53 and cmath53 . . . 128
1.6.3 Binary floating point, single precision: sreal and scplx . . . 134
1.6.4 Binary floating point, double precision: dreal and dcplx . . . 140
1.6.5 Binary floating point, extended precision: ereal and ecplx . . . 146
1.6.6 Binary floating point, quadruple precision: qreal and qcplx . . . 152
1.6.7 Binary floating point, octuple precision: oreal and ocplx . . . 158
1.6.8 Use of Numpy with scalar functions written in C#: np53, np53c . . . 163
1.6.9 Building the underlying C#, C/C++ and Pascal libraries . . . 164
1.7 Mathematical functions based on XlCalcNet2 (C#, can be called from Python) . . . 165
1.7.1 Binary floating point, multiple precision: mreal, mcplx . . . 165
1.7.2 Binary arbitrary precision ball: aflint and aflintc . . . 171
1.7.3 Binary floating point, single precision: sflint and sflintc . . . 176
1.7.4 Binary floating point, double precision: dflint and dflintc . . . 180
1.7.5 Binary floating point, extended precision: eflint and eflintc . . . 184
1.7.6 Binary floating point, quadruple precision: qflint and qflintc . . . 188
1.7.7 Binary floating point, octuple precision: oflint and oflintc . . . 192
1.7.8 Binary floating point, multiple precision: mflint, mflintc . . . 196
1.7.9 Building the underlying C# and C/C++ libraries . . . 199
1.8 Building user libraries and documenting them . . . 200
1.8.1 Building a library of user defined Python functions . . . 200
1.8.2 Building a library of user defined functions in C# . . . 200
1.8.3 Sphinx: building documentation for software with Python (html and pdf) . . . 200

2 Basic floating point functions **201**
2.1 Operator overloading, general real functions . . . 201
2.1.1 Operator overloading: scope and restrictions . . . 201
2.1.2 The cost of creating and destroying objects . . . 201
2.1.3 Raw addition of two floating point numbers . . . 201
2.1.4 Raw subtraction of two floating point numbers . . . 201
2.1.5 Raw multiplication of two floating point numbers . . . 202
2.1.6 Raw division of two floating point numbers . . . 202
2.1.7 Raw addition of a floating point number and a signed 32 bit integer . . . 202
2.1.8 Raw subtraction of a floating point number and a signed 32 bit integer . . . 202
2.1.9 Raw multiplication of a floating point number and a signed 32 bit integer . . . 203
2.1.10 Raw division of a floating point number and a signed 32 bit integer . . . 203
2.1.11 Fused multiplication and addition: $\mathrm{fma}(x, y, z)$ . . . 203
2.1.12 Maximum of two floating point numbers: $\mathrm{fmax}(x, y)$ . . . 204
2.1.13 Minimum of two floating point numbers: $\mathrm{fmin}(x, y)$ . . . 204
2.2 Machine constants, general . . . 205
2.2.1 Zero, positive zero . . . 205
2.2.2 Negative zero . . . 205
2.2.3 One . . . 205
2.2.4 Positive infinity . . . 206
2.2.5 Negative infinity . . . 206
2.2.6 NaN (Not a Number) . . . 206
2.3 Properties of numbers . . . 207
2.3.1 Test for signbit . . . 207
2.3.2 Test for a finite number . . . 207

2.3.3 Test for infinity . . . 207
2.3.4 Test for positive infinity . . . 207
2.3.5 Test for negative infinity . . . 208
2.3.6 Test for NaN . . . 208
2.3.7 Test for zero . . . 208
2.3.8 Test for one . . . 208
2.3.9 Test if a number is an integer . . . 209
2.3.10 Test if a number is a simple number (not an infinity or NaN) . . . 209
2.3.11 Test if a number is a regular number (not zero, an infinity or NaN) . . . 209
2.3.12 Test if a number is a normal number (not subnormal, zero, an infinity or NaN) . . . 209
2.3.13 Test if 2 numbers are unordered . . . 210
2.3.14 Test if a number fits in a signed 32 bit integer . . . 210
2.3.15 Test if a number fits in a signed 64 bit integer . . . 210
2.4 Integer related functions . . . 211
2.4.1 Integral value nearest x (rounding to nearest): $\mathrm{nearbyint}(x), \mathrm{rint}(x)$ . . . 211
2.4.2 32 bit integer nearest x (rounding to nearest): $\mathrm{lrint}(x)$ . . . 211
2.4.3 64 bit integer nearest x (rounding to nearest): $\mathrm{llrint}(x)$ . . . 211
2.4.4 Smallest integral value not less than x : $\mathrm{ceil}(x)$ . . . 212
2.4.5 Largest integral value not greater than x : $\mathrm{floor}(x)$ . . . 212
2.4.6 Nearest integral value not greater in magnitude than x : $\mathrm{trunc}(x)$ . . . 212
2.4.7 Nearest integral value, rounding halfway cases away from zero: $\mathrm{round}(x)$ . . . 213
2.4.8 Nearest 32 bit integer, rounding halfway cases away from zero: $\mathrm{lround}(x)$ . . . 213
2.4.9 Nearest 64 bit integer, rounding halfway cases away from zero: $\mathrm{llround}(x)$ . . . 213
2.5 Floating point functions for real numbers . . . 214
2.5.1 Efficient computation of $|x| \cdot \mathrm{sign}(y)$: $\mathrm{copysign}(x, y)$ . . . 214
2.5.2 Decomposition of x as $x = m \cdot 2^e; 0.5 < m < 1$: $\mathrm{frexp}(x)$ . . . 214
2.5.3 Integral value e, from the decomposition of x as $x = m \cdot 2^e; 1 < m < 2$: $\mathrm{logb}(x)$ . . . 215
2.5.4 32 bit integer e, from the decomposition of x as $x = m \cdot 2^e; 1 < m < 2$: $\mathrm{ilogb}(x)$ . . . 215
2.5.5 Efficient computation of $x \cdot 2^e$: $\mathrm{ldexp}(x, e), \mathrm{scalbn}(x, e), \mathrm{scalbln}(x, e)$ . . . 216
2.5.6 Positive difference between x and y: $\mathrm{fdim}(x, y)$ . . . 216
2.6 Fraction and remainder related functions . . . 218
2.6.1 Integral and fractional part of a floating point number: $\mathrm{modf}(x)$ . . . 218
2.6.2 Floating point remainder: $\mathrm{fmod}(x, y)$ . . . 218
2.6.3 IEEE floating point remainder: $\mathrm{remainder}(x, y)$ . . . 219
2.6.4 IEEE floating point remainder and part of quotient: $\mathrm{remquo}(x, y)$ . . . 219
2.7 Functions related to mantissa width and exponent range . . . 221
2.7.1 Machine Epsilon . . . 221
2.7.2 Unit in the last place . . . 221
2.7.3 Largest representable number . . . 221
2.7.4 Lowest representable number . . . 222
2.7.5 Smallest representable positive number . . . 222
2.7.6 Next representable floating point number: $\mathrm{nexttowards}(x, y)$ . . . 222
2.7.7 Next representable floating point number: $\mathrm{nextabove}(x)$ . . . 223
2.7.8 Next representable floating point number: $\mathrm{nextbelow}(x)$ . . . 223
2.8 Mathematical Constants . . . 224
2.8.1 Degree . . . 224
2.8.2 Golden ratio phi . . . 224
2.8.3 Natural logarithm of 2 . . . 224
2.8.4 Natural logarithm of 10 . . . 225
2.8.5 Pi (π) . . . 225
2.8.6 Euler e . . . 225
2.8.7 Euler-Mascheroni constant γ . . . 226
2.8.8 Apéry's constant . . . 226
2.8.9 Catalan's constant . . . 226

2.8.10 Glaisher's constant . . . 227
2.8.11 Khinchin's constant . . . 227
2.8.12 Imaginary One . . . 227

3 Elementary scalar functions (real and complex) 229
3.1 Complex components . . . 229
3.1.1 Absolute value of a real or complex number . . . 229
3.1.2 Sign of a real or complex number . . . 229
3.1.3 Real part of a real or complex number . . . 230
3.1.4 Imaginary part of a real or complex number . . . 230
3.1.5 Phase (or argument) of a real or complex number . . . 230
3.1.6 Conjugate of a real or complex number . . . 230
3.1.7 Polar representation of a real or complex number . . . 231
3.1.8 Rectangular coordinates calculated from the polar representation of a real or complex number . . . 231
3.2 Roots and quadratic, cubic, and quartic equations . . . 232
3.2.1 Square root, $\mathrm{sqrt}(x) = \sqrt{x}$ . . . 232
3.2.2 Reciprocal square root, $\mathrm{rsqrt}(x) = 1/\sqrt{x}$ . . . 233
3.2.3 Auxiliary function $\mathrm{sqrt1pm1}(x) = \sqrt{1+x} - 1$ . . . 234
3.2.4 Cube root, $\mathrm{cbrt}(x) = \sqrt[3]{x}$ . . . 235
3.2.5 Nth root, $\mathrm{nroot}(x, n) = \sqrt[n]{x}$ . . . 236
3.2.6 Unit root, $\mathrm{unitroot}(n)$ . . . 237
3.3 Exponential and related functions . . . 238
3.3.1 Exponential function $\exp(x) = e^x$ . . . 238
3.3.2 Auxiliary function $\mathrm{expj}(x) = e^{ix}$ . . . 239
3.3.3 Auxiliary function $\mathrm{expjpi}(x) = e^{i\pi x} = (-1)^x$ . . . 240
3.3.4 Exponential function with base 10, $\mathrm{exp10}(x) = 10^z$ . . . 240
3.3.5 Exponential function with base 2, $\mathrm{exp2}(x) = 2^x$ . . . 241
3.3.6 Auxiliary function $\mathrm{expm1}(x) = e^x - 1$ . . . 242
3.3.7 Auxiliary function $\mathrm{exp10m1}(x) = 10^x - 1$ . . . 243
3.3.8 Auxiliary function $\mathrm{exp2m1}(x) = 2^x - 1$ . . . 244
3.4 Logarithms and related functions . . . 245
3.4.1 Natural logarithm $\log(x)$ . . . 245
3.4.2 Logarithm with base 10, $\mathrm{log10}(x) = \log_{10}(x)$ . . . 246
3.4.3 Logarithm with base 2, $\mathrm{log2}(x) = \log_2(x)$ . . . 247
3.4.4 Logarithm with base b, $\mathrm{logbase}(x, b) = \log_b(x)$ . . . 248
3.4.5 Auxiliary function $\mathrm{log1p}(x) = \log(x+1)$ . . . 248
3.4.6 Auxiliary function $\mathrm{log10p1}(x) = \log_{10}(1+x)$ . . . 249
3.4.7 Auxiliary function $\mathrm{log2p1}(x) = \log_2(1+x)$ . . . 250
3.5 Power functions . . . 252
3.5.1 Square, x^2 . . . 252
3.5.2 Cube, x^3 . . . 252
3.5.3 Auxiliary function $\mathrm{powi}(x, n) = x^n$ . . . 253
3.5.4 Auxiliary function $\mathrm{hypot}(x, y) = \sqrt{x^2 + y^2}$ . . . 254
3.5.5 Power function, $\mathrm{pow}(x, y) = x^y$ . . . 254
3.5.6 Auxiliary function, $\mathrm{powm1}(x, y) = x^y - 1$ . . . 255
3.5.7 Auxiliary function, $\mathrm{pow1p}(x, y) = (1+x)^y$ . . . 256
3.5.8 Auxiliary function, $\mathrm{pow1pm1}(x, y) = (1+x)^y - 1$ . . . 257
3.6 Trigonometric functions, in radians . . . 259
3.6.1 Sine, $\sin(x)$ . . . 259
3.6.2 Cosine, $\cos(x)$ . . . 261
3.6.3 Tangent, $\tan(x)$ . . . 262
3.6.4 Cotangent, $\cot(x)$ . . . 263
3.6.5 Cosecant, $\csc(x)$ . . . 265
3.6.6 Secant, $\sec(x)$ . . . 266

3.6.7 Cardinal sine, $\mathrm{sinc}(x)$ . . . 268
3.7 Trigonometric functions, in multiples of π . . . 269
3.7.1 Auxiliary function $\mathrm{sinpi}(x) = \sin(\pi x)$ . . . 269
3.7.2 Auxiliary function $\mathrm{cospi}(x) = \cos(\pi x)$ . . . 269
3.7.3 Auxiliary function $\mathrm{tanpi}(x) = \tan(\pi x)$ . . . 270
3.7.4 Auxiliary function $\mathrm{cotpi}(x) = \cot(\pi x)$ . . . 271
3.7.5 Auxiliary function $\mathrm{cscpi}(x) = \csc(\pi x)$ . . . 271
3.7.6 Auxiliary function $\mathrm{secpi}(x) = \sec(\pi x)$ . . . 271
3.7.7 Auxiliary function $\mathrm{sincpi}(x) = \mathrm{sinc}(\pi x)$ . . . 271
3.8 Hyperbolic functions . . . 273
3.8.1 Hyperbolic sine, $\sinh(x)$ . . . 273
3.8.2 Hyperbolic cosine, $\cosh(x)$ . . . 274
3.8.3 Hyperbolic tangent, $\tanh(x)$ . . . 276
3.8.4 Hyperbolic cotangent, $\coth(x)$ . . . 277
3.8.5 Hyperbolic cosecant, $\mathrm{csch}(x)$ . . . 278
3.8.6 Hyperbolic secant, $\mathrm{sech}(x)$ . . . 280
3.9 Inverse trigonometric functions, in radians . . . 282
3.9.1 Inverse sine, $\mathrm{asin}(x)$ . . . 282
3.9.2 Inverse cosine, $\mathrm{acos}(x)$ . . . 283
3.9.3 Inverse tangent, $\mathrm{atan}(x)$ . . . 285
3.9.4 Inverse tangent, 2 arguments, $\mathrm{atan2}(y, x)$ . . . 286
3.9.5 Inverse cotangent, $\mathrm{acot}(x)$ . . . 287
3.9.6 Inverse cosecant, $\mathrm{acsc}(x)$ . . . 288
3.9.7 Inverse secant, $\mathrm{asec}(x)$ . . . 290
3.10 Inverse hyperbolic functions . . . 292
3.10.1 Inverse hyperbolic sine, $\mathrm{asinh}(x)$ . . . 292
3.10.2 Inverse hyperbolic cosine, $\mathrm{acosh}(x)$ . . . 293
3.10.3 Inverse hyperbolic tangent, $\mathrm{atanh}(x)$ . . . 294
3.10.4 Inverse hyperbolic cotangent, $\mathrm{acoth}(x)$ . . . 296
3.10.5 Inverse hyperbolic secant, $\mathrm{asech}(x)$ . . . 297
3.10.6 Inverse Hyperbolic Cosecant, $\mathrm{acsch}(x)$ . . . 298
3.11 Factorials, Gamma and related functions . . . 300
3.11.1 Gamma function, $\Gamma(x)$ . . . 300
3.11.2 Auxiliary function $\Gamma(x+1) - 1$ . . . 301
3.11.3 Log-gamma function, $\log\Gamma(x)$ . . . 302
3.11.4 Reciprocal Gamma function, $1/\Gamma(x)$ . . . 304
3.11.5 Factorial, $x!$ . . . 306
3.11.6 Double factorial, $x!!$ . . . 307
3.11.7 Rising factorial $a^{\overline{n}} = (a)_n$ . . . 308
3.11.8 Falling factorial, $(a)^{\underline{n}} = (a-n+1)^{\overline{n}}$ . . . 310
3.11.9 Ratio of gamma functions, $\Gamma(a)/\Gamma(b)$ . . . 310
3.11.10 Gamma-delta ratio, $\Gamma(a)/\Gamma(a+\delta)$ . . . 310
3.11.11 Beta function, $B(a,b) = \Gamma(a)\Gamma(b)/\Gamma(a+b)$ . . . 311
3.11.12 Binomial coefficient, ${}_nC_k = (k \cdot B(k, n-k+1))^{-1}$ . . . 312
3.12 Miscellaneous functions . . . 313
3.12.1 Lambert W function, $W_0(x)$ . . . 313
3.12.2 Lambert W function, $W_{-1}(x)$ . . . 314
3.12.3 Lambert W (general case) . . . 314
3.12.4 Arithmetic-geometric mean . . . 315

4 Statistical Distributions **317**
4.1 Introduction to random variables and distributions . . . 317
4.1.1 Elementary symbolic algebra of random variables . . . 317
4.1.2 Linear transformations of random variables . . . 319

4.1.3 Random variables having mixture distributions . . . 320
4.1.4 Linear combinations of independent random variables . . . 321
4.1.5 The log-transform of continuous random variables . . . 322
4.2 Base class for univariate distributions . . . 323
4.2.1 Boost: Cumulative distribution function . . . 323
4.2.2 Boost: Survival function . . . 323
4.2.3 Hazard function . . . 324
4.2.4 Cumulative Hazard Function . . . 324
4.2.5 Boost: Quantile function . . . 324
4.2.6 Boost: Inverse survival function . . . 325
4.2.7 Boost: Mode . . . 325
4.2.8 Boost: Expected value (mean) . . . 325
4.2.9 Boost: Median . . . 325
4.2.10 Boost: Variance . . . 326
4.2.11 Boost: Standard deviation . . . 326
4.2.12 Boost: Skewness . . . 326
4.2.13 Boost: Kurtosis . . . 326
4.2.14 Boost: Kurtosis excess . . . 327
4.2.15 Boost: Support, lower endpoint . . . 327
4.2.16 Boost: Support, upper endpoint . . . 327
4.2.17 Boost: Range, lower endpoint . . . 328
4.2.18 Boost: Range, upper endpoint . . . 328
4.2.19 Characteristic function . . . 328
4.2.20 Moment generating function . . . 329
4.2.21 Cumulant generating function . . . 329
4.2.22 Raw Moments . . . 330
4.2.23 Central Moments . . . 330
4.2.24 Cumulants . . . 331
4.3 Base class for continuous univariate distributions . . . 332
4.3.1 Probability density function . . . 332
4.3.2 Probability sparsity function . . . 332
4.3.3 Differerential entropy . . . 333
4.3.4 Negative loglikelihood function . . . 333
4.3.5 Logarithm of the probability density function . . . 333
4.4 Base class for discrete univariate distributions . . . 334
4.4.1 Probability mass function . . . 334
4.4.2 Probability generating function . . . 334
4.4.3 Vector containing all values of the pmf . . . 335
4.4.4 Entropy . . . 335
4.4.5 Logarithm of the probability mass function . . . 336
4.5 Closed form distributions, based on elementary functions . . . 337
4.5.1 Boost: Arcsine Distribution . . . 337
4.5.2 Boost: Cauchy distribution . . . 341
4.5.3 Boost: Exponential distribution . . . 344
4.5.4 Boost: Gumbel (Generalized Extreme Value distribution Type-I) distribution . . . 348
4.5.5 Boost: Hyperexponential Distribution . . . 352
4.5.6 !!!Boost: Kumaraswamy distribution . . . 356
4.5.7 Boost: Laplace distribution . . . 360
4.5.8 Boost: Logistic distribution . . . 364
4.5.9 Boost: Pareto distribution . . . 368
4.5.10 Boost: Rayleigh distribution . . . 372
4.5.11 Boost: Triangular Distribution . . . 376
4.5.12 Boost: Uniform distribution . . . 380
4.5.13 Boost: Weibull (Minimum-Type-III) distribution . . . 384

4.5.14 Dagum (Burr Type III) distribution . . . 388
4.5.15 Fisk (log-logistic) distribution . . . 391
4.5.16 Fréchet (Maximum/Minimum-Type-II or Inverse Weibull) distribution . . . 394
4.5.17 Generalized Extreme Value (Maximum) or GEV distribution . . . 397
4.5.18 Generalized Pareto distribution . . . 400
4.5.19 Gompertz-Makeham distribution . . . 403
4.5.20 Lomax distribution . . . 406
4.5.21 Shifted Gompertz distribution . . . 409
4.5.22 Singh-Maddala (Burr Type XII) distribution . . . 412
4.6 Closed form distributions, based on the error function . . . 415
4.6.1 !!!Boost: Lévy distribution . . . 416
4.6.2 Boost: Lognormal (Johnson S_L) distribution . . . 419
4.6.3 !!!Boost: Moyal Distribution . . . 423
4.6.4 Boost: Normal (Johnson S_N) distribution . . . 427
4.6.5 Boost: Skew normal Distribution . . . 431
4.6.6 Boost: Wald (or Inverse Gaussian) distribution . . . 435
4.6.7 Birnbaum-Saunders Distribution . . . 438
4.6.8 Exponentially Modified Gaussian (EMG) distribution . . . 442
4.6.9 Folded normal distribution . . . 445
4.6.10 Half-normal distribution . . . 448
4.6.11 Johnson S_B distribution . . . 451
4.6.12 Johnson S_U distribution . . . 454
4.6.13 Normal maximum distribution, $\rho_{ij,i\neq j} = 0$ . . . 457
4.6.14 Normal maximum modulus distribution, $\rho_{ij,i\neq j} = 0$ . . . 460
4.6.15 Sinh-arcsinh normal distribution . . . 463
4.6.16 Truncated normal distribution . . . 466
4.7 Closed form distributions, based on the incomplete gamma function . . . 469
4.7.1 !!!Boost: Chi Distribution . . . 469
4.7.2 Boost: Chi2 distribution . . . 473
4.7.3 Boost: Gamma (Pearson Type III, Erlang) distribution . . . 478
4.7.4 Boost: Inverse chisquared distribution . . . 482
4.7.5 Boost: Inverse Gamma (Pearson Type V) distribution . . . 486
4.7.6 !!!Boost: Maxwell Distribution . . . 490
4.7.7 !!!Boost: Nakagami distribution . . . 494
4.7.8 Amoroso distribution . . . 498
4.7.9 Distribution of the logarithm of a χ^2 random variable . . . 501
4.7.10 Hypoexponential (Generalized Erlang) Distribution . . . 504
4.7.11 Lindley distribution (generalized) . . . 508
4.7.12 Skew exponential power distribution . . . 511
4.7.13 Stacy (generalized gamma) distribution . . . 514
4.8 Closed form distributions, based on the incomplete beta function . . . 517
4.8.1 Boost: Beta (Pearson Type I and II) distribution . . . 517
4.8.2 Boost: Central Fisher F distribution . . . 522
4.8.3 Boost: Student t (Pearson Type VII) distribution . . . 527
4.8.4 Distribution of the negative logarithm of a beta variable . . . 531
4.8.5 Beta-prime (Pearson Type VI) distribution . . . 534
4.8.6 Generalized Beta (Type 1) distribution . . . 537
4.8.7 Generalized Beta (Type 2) distribution . . . 540
4.8.8 Generalized logistic distribution (JKB Types I - IV) . . . 543
4.8.9 Generalized beta-exponential distribution . . . 546
4.8.10 Feller-Pareto distribution . . . 549
4.8.11 Fisher z distribution . . . 552
4.8.12 Skew t-distribution (Jones) . . . 556
4.8.13 Pearson's rho distribution (under H_0) . . . 559

4.9 Noncentral distributions . . . 562
4.9.1 Boost: Noncentral χ^2 distribution . . . 562
4.9.2 Boost: Noncentral Student t distribution . . . 567
4.9.3 Boost: Noncentral Fisher F distribution . . . 571
4.9.4 Boost: Noncentral Beta Type I distribution . . . 576
4.9.5 Noncentral Chi distribution . . . 581
4.9.6 Rice (Nakagami-n) distribution . . . 584
4.9.7 Noncentral distribution of the sample correlation coefficient . . . 587
4.9.8 Distribution of the logarithm of a noncentral Beta Type II variable . . . 591
4.9.9 Noncentral distribution (Type I) of Fisher's R^2 . . . 595
4.9.10 Distribution of the logarithm of a noncentral Fisher $1 - R^2$ variable . . . 600
4.9.11 Doubly non-central Student t distribution . . . 604
4.9.12 Doubly non-central Fisher F distribution . . . 607
4.10 Distributions related to multiple comparisons of means . . . 612
4.10.1 Overview and literature . . . 612
4.10.2 Normal maximum distribution, $\rho_{ij,i\neq j} = \rho$ . . . 613
4.10.3 Normal maximum modulus distribution, $\rho_{ij,i\neq j} = \rho$ . . . 616
4.10.4 Normal maximum distribution, $\rho_{ij,i\neq j} = \lambda_i\lambda_j$ . . . 619
4.10.5 Normal maximum modulus distribution, $\rho_{ij,i\neq j} = \lambda_i\lambda_j$ . . . 622
4.10.6 Normal range distribution . . . 625
4.10.7 Studentized maximum distribution . . . 628
4.10.8 Studentized maximum modulus distribution . . . 631
4.10.9 Distribution of Dunnett's t, one-sided . . . 634
4.10.10 Distribution of Dunnett's t, two-sided . . . 637
4.10.11 Nair's t-distribution . . . 640
4.10.12 Halperin's t-distribution . . . 643
4.10.13 Nelson's h-distribution . . . 646
4.10.14 Studentized range distribution . . . 649
4.11 Distributions related to multivariate statistical analysis . . . 652
4.11.1 Distribution of the sum of the negative logarithms of independent beta variables . . . 652
4.11.2 Distribution of the product of independent beta variables . . . 656
4.11.3 Distribution of Wilks' Λ . . . 661
4.11.4 Distribution of Wilks' L_{vc} . . . 665
4.11.5 Distribution of Wilks' L_{vcm} . . . 669
4.11.6 Distribution of Wilks' test of independence of p variates . . . 673
4.11.7 Distribution of Wilks' test of independence of k groups of variates . . . 677
4.11.8 Distribution of Mauchly's test of sphericity vs general structure . . . 681
4.11.9 Distribution of Box's test of equality of covariance matrices, equal sample sizes . . . 685
4.11.10 Distribution of Box's test of equality of k covariance matrices, unequal sample sizes . . . 689
4.11.11 Distribution of Box's test for same multivariate normal distributions, unequal sample sizes . . . 694
4.11.12 Distribution of the modified likelihood ratio test (LRT) for a given covariance matrix . . . 698
4.11.13 Distribution of the modified likelihood ratio test (LRT) for a given covariance matrix and mean vector . . . 703
4.11.14 Central distribution of Roy's largest root . . . 707
4.11.15 Central distribution of Pillai's V . . . 710
4.11.16 Central distribution of Hotelling's T^2 . . . 713
4.11.17 Noncentral Distribution of Wilks' Λ: MANOVA . . . 716
4.11.18 Noncentral Distribution of Wilks' Λ: Canonical Correlation . . . 720
4.12 Miscellaneous continuous distributions . . . 724
4.12.1 Boost: Kolmogorov-Smirnov distribution (limiting form) . . . 724
4.12.2 Boost: Landau Distribution . . . 729
4.12.3 Boost: Holtsmark distribution . . . 732
4.12.4 Boost: Map-Airy distribution . . . 737
4.12.5 Boost: Saspoint5 distribution . . . 742
4.13 Elementary discrete (lattice) distributions . . . 747

4.13.1 Boost: Bernoulli distribution . . . 747
4.13.2 Boost: Geometric distribution . . . 751
4.13.3 Boost: Poisson distribution . . . 756
4.13.4 Boost: Binomial distribution . . . 761
4.13.5 Boost: Negative binomial distribution . . . 766
4.13.6 Boost: Classical hypergeometric distribution . . . 771
4.14 Discrete (lattice) distributions related to (stratified) rank tests . . . 776
4.14.1 Wilcoxon signed rank T distribution, continuous data . . . 776
4.14.2 Noncentral Wilcoxon signed rank T distribution, Bennett alternatives . . . 781
4.14.3 Mann-Whitney U distribution, continuous data . . . 784
4.14.4 Noncentral Mann-Whitney U distribution, Lehmann alternatives . . . 789
4.14.5 Noncentral Mann-Whitney U distribution, Milton alternatives . . . 792
4.14.6 Kendall's tau distribution, continuous data . . . 795
4.14.7 Jonckheere-Terpsta T distribution, continuous data . . . 800
4.14.8 Generalized Page L distribution, continuous data . . . 805
4.14.9 Noncentral generalized Page L distribution, Milton alternatives . . . 808
4.15 Discrete (non-lattice) distributions related to rank tests . . . 811
4.15.1 Cochran-Friedman-Quade distribution . . . 811
4.15.2 Kruskal-Wallis distribution . . . 814

5 Numerical calculus **817**
5.1 Introduction . . . 817
5.1.1 Delegates, lambda expressions, callback functions: an example . . . 817
5.1.2 Usage in Python . . . 818
5.1.3 Usage in CSharp . . . 818
5.2 DAMath: Numerical Rootfinding and Minimization . . . 820
5.2.1 Quadratic Equation, Real Coefficients . . . 820
5.2.2 Cubic Equation, Real Coefficients . . . 821
5.2.3 Brent's algorithm for finding a local minimum . . . 822
5.2.4 Modified Brent's algorithm for finding a local minimum . . . 825
5.2.5 Rootfinding: Brent/Dekker algorithm . . . 826
5.2.6 Rootfinding: Simplified Brent/Dekker algorithm . . . 827
5.3 Boost/Math: Root Finding and Minimization Algorithms . . . 828
5.3.1 Root Finding Without Derivatives (TOM 748 algorithm) . . . 828
5.3.2 Root Finding With Derivatives: Newton-Raphson . . . 829
5.3.3 Root Finding With Derivatives: Halley . . . 830
5.3.4 Root Finding With Derivatives: Schröder . . . 831
5.3.5 Locating Function Minima using Brent's algorithm . . . 832
5.4 Mpmath: Rootfinding and optimization . . . 833
5.4.1 General root-finding interface . . . 833
5.4.2 Bisection algorithm . . . 833
5.4.3 Secant algorithm . . . 834
5.4.4 Illinois, Pegasus, Anderson algorithms . . . 835
5.4.5 Muller algorithm . . . 836
5.4.6 Ridder algorithm . . . 836
5.4.7 Brent algorithm (to be implemented from Scipy brent) . . . 837
5.4.8 Newton algorithm . . . 837
5.4.9 Newton-Steffenson algorithm (ANewton) . . . 837
5.4.10 Modified Newton algorithm (MNewton) . . . 838
5.4.11 Halley algorithm . . . 839
5.4.12 Roots of a vector function (MDNewton, to be implemented) . . . 839
5.4.13 Levenberg-Marquardt algorithm . . . 840
5.4.14 BFGS algorithm. . . . 840
5.4.15 L-BFGS algorithm. . . . 840

5.4.16 Conjugate gradient. . . . 840
5.5 DAMath: Numerical Quadrature . . . 841
5.5.1 General error codes for Amath integration functions, type 1 . . . 841
5.5.2 General error codes for Amath integration functions, type 2 . . . 841
5.5.3 Global adaptive quadrature by Forsythe, Malcolm, Moler (quanc8) . . . 842
5.5.4 21-point Gauss-Kronrod rule, finite interval (qags) . . . 843
5.5.5 15-point Gauss-Kronrod rule, infinite interval (qagi) . . . 844
5.5.6 Cauchy principal value, finite interval (qawc) . . . 845
5.5.7 Double Exponential (DE) transformation, finite interval (intde) . . . 846
5.5.8 DE transformation, infinite interval, no oscillatory factor (intdei) . . . 847
5.5.9 DE transformation, infinite interval, oscillatory factor (intdeo) . . . 848
5.6 Boost/Math: Numerical integration . . . 849
5.6.1 Trapezoidal Quadrature . . . 849
5.6.2 Gauss-Legendre quadrature . . . 850
5.6.3 Gauss-Kronrod Quadrature . . . 851
5.6.4 Double-exponential quadrature: tanh_sinh . . . 852
5.6.5 Double-exponential quadrature: sinh_sinh . . . 853
5.6.6 Double-exponential quadrature: exp_sinh . . . 854
5.6.7 Fourier Integral, Cosine . . . 855
5.6.8 Fourier Integral, Sine . . . 856
5.6.9 Calculating the pdf from the characteristic function . . . 856
5.6.10 Calculating the cdf from the characteristic function . . . 856
5.7 Mpmath: Numerical integration . . . 859
5.7.1 General quadrature interface . . . 859
5.7.2 Quadrature with subdivision . . . 862
5.7.3 Quadrature of oscillatory functions (Filon) . . . 863
5.7.4 Verified numerical integration (Okayama) . . . 865
5.7.5 Specialized Gauss quadrature rules . . . 867
5.8 Mpmath: Numerical inverse Laplace transform . . . 871
5.8.1 General inverse Laplace transform interface . . . 871
5.8.2 Talbot method . . . 873
5.8.3 Stehfest method . . . 874
5.8.4 de Hoog, Knight, and Stokes method . . . 875
5.8.5 Cohen method . . . 876
5.9 Boost/Odeint: Ordinary differential equations . . . 877
5.9.1 Runge-Kutta 4 method, constant stepper . . . 878
5.9.2 Cash-Karp method, constant stepper . . . 879
5.9.3 Dormand-Prince 5 method, constant stepper . . . 880
5.9.4 Fehlberg 78 method, constant stepper . . . 881
5.9.5 Adams-Bashforth-Moulton, constant stepper . . . 882
5.9.6 Cash-Karp method, adaptive stepper . . . 883
5.9.7 Dormand-Prince 5 method, adaptive stepper . . . 884
5.9.8 Fehlberg 78 method, adaptive stepper . . . 885
5.9.9 Bulirsch-Stoer method, adaptive stepper . . . 886
5.9.10 Dormand-Prince 5 method, dense output stepper . . . 887
5.9.11 Bulirsch-Stoer method, dense output stepper . . . 888
5.10 Mpmath: Numerical differentiation . . . 889
5.10.1 First derivative, using the complex-step derivative approximation . . . 889
5.10.2 Second derivative, using the complex-step derivative approximation . . . 889
5.10.3 Gradient, using the complex-step derivative approximation . . . 889
5.10.4 Jacobi matrix, using the complex-step derivative approximation . . . 889
5.10.5 Nth numerical (partial) derivative, using finite differences or numerical quadrature . . . 890
5.10.6 Function object which evaluates the nth derivative of a given function . . . 892
5.10.7 Forward difference, based on a given sequence . . . 892

5.10.8 Generating a sequence of derivatives . . . 892
5.10.9 Composition of derivatives . . . 893
5.10.10 Composition of exponential of derivatives . . . 893
5.10.11 Fractional derivatives / differintegration . . . 894
5.10.12 Taylor series . . . 895
5.10.13 Solving an ODE using high-order Taylor series . . . 895
5.11 Mpmath: Asymptotic expansions . . . 898
5.11.1 Edgeworth expansion: general approximation of the pdf, cdf and sf . . . 898
5.11.2 Cornish-Fisher expansion: general approximation of the qtf and isf . . . 899
5.11.3 Sheppard correction, cumulants . . . 900
5.11.4 The Sheppard correction, cumulant generating function . . . 900
5.11.5 Luggannini-Rice expansion: general approximation of the pdf, cdf, and sf . . . 901
5.11.6 Jensen expansion: general approximation of the qtf and isf . . . 902
5.11.7 Box-Davis expansion: general approximation of the pdf, cdf and sf . . . 902
5.11.8 Box-Davis expansion: general approximation of the qtf and isf (for $\omega_1 = 0$) . . . 903
5.12 Mpmath: Function approximation . . . 905
5.12.1 Pade approximation . . . 905
5.12.2 Chebyshev approximation . . . 905
5.12.3 Fourier series . . . 906
5.12.4 Fourier series evaluation . . . 907
5.13 Mpmath: Sums, products, limits and extrapolation . . . 908
5.13.1 Summation of infinite series . . . 908
5.13.2 Summation using the Euler-Maclaurin formula . . . 914
5.13.3 Summation using the Abel-Plana formula . . . 915
5.13.4 Products . . . 915
5.13.5 Limits, general . . . 917
5.13.6 Richardson extrapolation . . . 919
5.13.7 Shanks extrapolation . . . 919
5.13.8 Levin extrapolation . . . 921
5.13.9 Cohan alternating extrapolation . . . 924
5.14 Mpmath: Polynomials . . . 925
5.14.1 Polynomial evaluation . . . 926
5.14.2 Polynomial roots . . . 926
5.15 Eigen/MinPack: non linear optimization . . . 928
5.15.1 Multidimensional Rootfinding: Powell Hybrid . . . 928
5.15.2 Nonlinear LeastSquares: Levenberg-Marquardt . . . 930
5.16 Eigen/CppOptLib: multidimensional optimization . . . 931
5.16.1 Nelder-Mead Solver . . . 933
5.16.2 CMAes solver . . . 935
5.16.3 BFGS Solver . . . 937
5.16.4 L-BFGS Solver . . . 939
5.16.5 Gradient descent solver . . . 941
5.16.6 Conjugate gradient descent solver . . . 943
5.16.7 Newton descent solver (description needs correction) . . . 945

6 Eigen: Dense and Sparse Matrices **947**
6.1 Creating scalars and matrices . . . 947
6.1.1 Creating a matrix, and converting from compatible data types . . . 947
6.1.2 Creating a matrix of zeros . . . 947
6.1.3 Creating a matrix of ones . . . 948
6.1.4 Creating an identity matrix . . . 948
6.1.5 Creating a general random matrix . . . 948
6.1.6 Creating a symmetric random matrix . . . 948
6.1.7 Creating a self-adjoint random matrix . . . 949

6.1.8 Creating a positive definite self-adjoint matrix . . . 949
6.1.9 Creating a matrix with linearly increasing values . . . 949
6.2 Read-only properties: information about a matrix . . . 950
6.2.1 Rows of a matrix . . . 950
6.2.2 Columns of a matrix . . . 950
6.2.3 Size of a matrix . . . 950
6.3 Accessing and setting parts of a matrix . . . 951
6.3.1 Getting and setting a matrix coefficient . . . 951
6.3.2 Getting and setting a block . . . 951
6.3.3 Getting and setting a matrix row . . . 952
6.3.4 Getting and setting a matrix column . . . 952
6.3.5 Getting and setting a diagonal . . . 953
6.3.6 Getting and setting a triangular view . . . 954
6.4 Changing the shape of a matrix and/or the order of coefficients . . . 955
6.4.1 Sorting a whole matrix . . . 955
6.4.2 Sorting the rows of a matrix by a given column . . . 955
6.4.3 Resize a matrix . . . 956
6.4.4 Resize a matrix like another matrix . . . 956
6.4.5 Conservatively resize a matrix . . . 957
6.4.6 Convert vector to diagonal matrix . . . 957
6.4.7 Adjoint of a matrix . . . 958
6.4.8 Conjugate of a matrix . . . 958
6.4.9 Transpose of a matrix . . . 959
6.4.10 Full Reverse of a matrix . . . 960
6.4.11 Row-wise Reverse of a matrix . . . 960
6.4.12 Column-wise Reverse of a matrix . . . 960
6.4.13 Full Replication of a matrix . . . 961
6.4.14 Row-wise Replication of a matrix . . . 961
6.4.15 Column-wise Replication of a matrix . . . 962
6.4.16 Horizontal concatenation of two matrices . . . 962
6.4.17 Vertical concatenation of two matrices . . . 963
6.5 Basic arithmetic operations . . . 964
6.5.1 Matrix deep copy (unary plus) . . . 964
6.5.2 Matrix negation (unary minus) . . . 964
6.5.3 General matrix addition . . . 965
6.5.4 Matrix addition of a vector as diagonal matrix . . . 965
6.5.5 Matrix: addition of a scalar . . . 966
6.5.6 General matrix subtraction . . . 966
6.5.7 Matrix: subtraction of a scalar . . . 967
6.5.8 General matrix multiplication (“gemm”) . . . 967
6.5.9 Arithmetic comparisons with a scalar or a matrix . . . 969
6.6 Descriptive Statistics . . . 971
6.6.1 Partial Sum . . . 971
6.6.2 Partial Product . . . 971
6.6.3 Partial Arithmetic Mean . . . 971
6.6.4 Partial Minimal Coefficient . . . 971
6.6.5 Partial Maximal Coefficient . . . 971
6.6.6 Trace . . . 971
6.6.7 Partial Squared Norm . . . 972
6.6.8 Partial Norm . . . 972
6.6.9 Partial Stable Norm . . . 972
6.6.10 Covariance matrix . . . 972
6.6.11 Correlation matrix . . . 972
6.7 Standard decompositions and linear solving . . . 973

6.7.1 Cholesky Decomposition with Pivoting . . . 973
6.7.2 LU Decomposition with partial Pivoting . . . 979
6.7.3 LU Decomposition with full Pivoting . . . 984
6.7.4 Cholesky Decomposition without Pivoting . . . 989
6.7.5 QR Decomposition without Pivoting . . . 993
6.7.6 QR Decomposition with column Pivoting . . . 997
6.7.7 QR Decomposition with full Pivoting . . . 1003
6.7.8 Complete orthogonal decomposition (COD) . . . 1009
6.8 Singular Value and Eigen (selfadjoint) decompositions . . . 1016
6.8.1 Singular Value Decomposition, only singular values . . . 1016
6.8.2 Singular Value Decomposition, singular values and thin singular vectors . . . 1019
6.8.3 Singular Value Decomposition, singular values and full singular vectors . . . 1024
6.8.4 Symmetric/Hermitian Eigensystem, only eigen values . . . 1030
6.8.5 Symmetric/Hermitian Eigensystem, eigenvalues and eigenvectors . . . 1033
6.8.6 Generalized Selfadjoint Eigensystem, only eigenvalues . . . 1038
6.8.7 Generalized Selfadjoint Eigensystem: eigenvalues and eigenvectors . . . 1041
6.8.8 Tridiagonalization . . . 1046
6.9 Eigen decompositions of general square matrices . . . 1050
6.9.1 Matrix balancing and eigenvalue/eigenvector computation . . . 1050
6.9.2 Hessenberg Decomposition . . . 1051
6.9.3 Schur Decomposition . . . 1054
6.9.4 Eigensystem of a general square matrix: only eigenvalues . . . 1056
6.9.5 Eigensystem of a general square matrix: eigenvalues and eigenvectors . . . 1059
6.9.6 Real QZ Decomposition . . . 1063
6.9.7 PseudoEigenSystem . . . 1065
6.9.8 Real Generalized Nonsymmetric Eigenvalues . . . 1067
6.9.9 Real Generalized Nonsymmetric Eigensystem . . . 1069
6.10 Eigen: Polynomials . . . 1071
6.10.1 Building a polynomial from its roots . . . 1071
6.10.2 Polynomial evaluation . . . 1071
6.10.3 Polynomial roots . . . 1071
6.11 Eigen: Fast Fourier Transform . . . 1072
6.11.1 Forward transform . . . 1072
6.11.2 Inverse transform . . . 1072
6.12 Eigen and Numpy (Multiprecision): Functions of matrix argument . . . 1075
6.12.1 Matrix Exponential . . . 1075
6.12.2 Matrix Sine . . . 1076
6.12.3 Matrix Cosine . . . 1077
6.12.4 Matrix Hyperbolic Sine . . . 1078
6.12.5 Matrix Hyperbolic Cosine . . . 1079
6.12.6 Matrix Square Root . . . 1081
6.12.7 Matrix Logarithm . . . 1083
6.12.8 Matrix power . . . 1085

7 Numpy: use with multiprecision data types 1086
7.1 Numpy array creation from shape or value . . . 1086
7.1.1 Conversion from integer, float or complex array . . . 1086
7.1.2 Ones on the diagonal and zeros elsewhere: numpy.eye . . . 1089
7.1.3 Identity array: numpy.identity . . . 1089
7.1.4 Array of ones: numpy.ones . . . 1090
7.1.5 Array of ones: numpy.ones_like . . . 1090
7.1.6 Array of zeros: numpy.zeros . . . 1091
7.1.7 Array of zeros: numpy.zeros_like . . . 1091
7.1.8 Array of constant: numpy.full . . . 1092

7.1.9 Array of constant: numpy.full_like . . . 1093
7.1.10 Array with ones at and below the given diagonal and zeros elsewhere: numpy.tri . . . 1094
7.2 Numpy array creation from existing data . . . 1095
7.2.1 Array from object: numpy.array . . . 1095
7.2.2 Array from object: numpy.asarray . . . 1096
7.2.3 Array from object: numpy.asanyarray . . . 1097
7.2.4 Array from data in a text or binary file: numpy.fromfile . . . 1098
7.2.5 Array from a function: numpy.fromfunction . . . 1098
7.2.6 Array from an iterable object: numpy.fromiter . . . 1099
7.2.7 Array from text data in a string: numpy.fromstring . . . 1100
7.2.8 Array from text data in a formatted file: numpy.loadtxt . . . 1101
7.2.9 Array from text data in a text file (can handle missing values): numpy.genfromtxt . . . 1103
7.3 Building special arrays for numerical work . . . 1105
7.3.1 Evenly spaced values within a given interval: numpy.arange . . . 1105
7.3.2 Evenly spaced values within a given interval: numpy.linspace . . . 1106
7.3.3 Evenly spaced values on a log scale: numpy.logspace . . . 1107
7.3.4 Evenly spaced values on a log scale (a geometric progression): numpy.geomspace . . . 1108
7.3.5 Extract a diagonal or construct a diagonal array: numpy.diag . . . 1109
7.3.6 Extract specified diagonals: numpy.diagonal . . . 1111
7.3.7 Two-dimensional array with the flattened input as a diagonal: numpy.diagflat . . . 1112
7.3.8 Lower triangle of an array: numpy.tril . . . 1112
7.3.9 Upper triangle of an array: numpy.triu . . . 1113
7.3.10 Vandermonde matrix.: numpy.vander . . . 1113
7.4 Numpy indexing . . . 1115
7.4.1 Single element indexing . . . 1115
7.4.2 Slicing and striding . . . 1115
7.4.3 Dimensional indexing tools . . . 1117
7.4.4 Broadcasting Overview . . . 1117
7.4.5 General Broadcasting Rules . . . 1118
7.4.6 Broadcastable arrays . . . 1118
7.4.7 Assigning values to indexed arrays . . . 1120
7.5 Numpy basic array manipulation routines . . . 1121
7.5.1 Copy values from one array to another: numpy.copyto . . . 1121
7.5.2 Get the shape of an array: numpy.shape . . . 1121
7.5.3 Reshape an array without changing its data: numpy.reshape . . . 1121
7.5.4 Get a contiguous flattened array: numpy.ravel . . . 1122
7.5.5 1-D iterator over the array: ndarry.flat . . . 1123
7.5.6 Get a copy of the array collapsed into one dimension: ndarry.flatten . . . 1124
7.6 Numpy array manipulation: Transpose-like operations . . . 1125
7.6.1 Move axes of an array to new positions: numpy.flatten . . . 1125
7.6.2 Interchange two axes of an array: numpy.swapaxes . . . 1125
7.6.3 Get an array with axes transposed: numpy.transpose . . . 1125
7.7 Numpy array manipulation: Changing number of dimensions . . . 1127
7.7.1 Convert inputs to arrays with at least one dimension: numpy.atleast_1d . . . 1127
7.7.2 Convert inputs to arrays with at least two dimensions: numpy.atleast_2d . . . 1127
7.7.3 Convert inputs to arrays with at least two dimensions: numpy.atleast_3d . . . 1127
7.7.4 Broadcast an array to a new shape: numpy.broadcast_to . . . 1128
7.7.5 Broadcast any number of arrays against each other: numpy.broadcast_arrays . . . 1128
7.7.6 Expand the shape of an array: numpy.expand_dims . . . 1128
7.7.7 Remove axes of length one from an array: numpy.squeeze . . . 1129
7.8 Numpy array manipulation: Joining arrays . . . 1131
7.8.1 Join a sequence of arrays along an existing axis: numpy.concatenate . . . 1131
7.8.2 Join a sequence of arrays along an existing axis: numpy.stack . . . 1131
7.8.3 Assemble an nd-array from nested lists of blocks: numpy.block . . . 1132

7.8.4 Stack arrays in sequence vertically (row wise): numpy.vstack . . . 1133
7.8.5 Stack arrays in sequence horizontally (column wise): numpy.hstack . . . 1134
7.8.6 Stack arrays in sequence depth wise (along third axis): numpy.dstack . . . 1134
7.8.7 Stack 1-D arrays as columns into a 2-D array: numpy.column_stack . . . 1135
7.9 Numpy array manipulation: Splitting and tiling arrays . . . 1136
7.9.1 Split an array into multiple sub-arrays as views: numpy.split . . . 1136
7.9.2 Split an array into multiple sub-arrays: numpy.array_split . . . 1136
7.9.3 Split array into multiple sub-arrays along the 3rd axis (depth): numpy.dsplit . . . 1136
7.9.4 Split an array into multiple sub-arrays horizontally (column-wise): numpy.hsplit . . . 1137
7.9.5 Split an array into multiple sub-arrays vertically (row-wise): numpy.vsplit . . . 1138
7.9.6 Construct an array by repeating a given array: numpy.tile . . . 1138
7.9.7 Repeat each element of an array after themselves: numpy.repeat . . . 1139
7.10 Numpy array manipulation: Adding and removing elements . . . 1140
7.10.1 Pad an array: numpy.pad . . . 1140
7.10.2 Return a new array with sub-arrays along an axis deleted: numpy.delete . . . 1141
7.10.3 Insert values along the given axis before the given indices: numpy.insert . . . 1141
7.10.4 Append values to the end of an array: numpy.append . . . 1142
7.10.5 Trim zeros from a 1-D array: numpy.trim_zeros . . . 1143
7.10.6 Find the unique elements of an array: numpy.unique . . . 1143
7.11 Numpy array manipulation: Rearranging elements . . . 1145
7.11.1 Reverse the order of elements in an array along the given axis: numpy.flip . . . 1145
7.11.2 Reverse the order of elements along axis 1 (left/right): numpy.fliplr . . . 1145
7.11.3 Reverse the order of elements along axis 0 (up/down): numpy.flipud . . . 1146
7.11.4 Roll array elements along a given axis: numpy.roll . . . 1146
7.11.5 Rotate an array by 90 degrees: numpy.rot90 . . . 1147
7.12 Numpy array manipulation: Sorting . . . 1148
7.12.1 Sorted copy of an array: numpy.sort . . . 1148
7.12.2 Indirect stable sort using a sequence of keys: numpy.lexsort . . . 1149
7.12.3 Indices that would sort an array: numpy.argsort . . . 1150
7.12.4 Matching 1d index and data slices: numpy.take_along_axis . . . 1151
7.12.5 Sorting a complex array: numpy.sort_complex . . . 1151
7.13 Numpy array manipulation: Searching . . . 1152
7.13.1 Indices of the maximum values along an axis: numpy.argmax . . . 1152
7.13.2 Get indices of the minimum values along an axis: numpy.argmin . . . 1152
7.13.3 Find the indices of array elements that are non-zero, grouped by element: numpy.argwhere . . . 1153
7.13.4 Get the indices of array elements that are non-zero: numpy.nonzero . . . 1154
7.13.5 Return elements depending on a condition: numpy.where . . . 1154
7.13.6 Return an array drawn from elements in choicelist, depending on a condition: numpy.select . . . 1155
7.14 Numpy mathematical functions: Sums, products, differences . . . 1156
7.14.1 Product of array elements: numpy.prod . . . 1156
7.14.2 Sum of array elements: numpy.sum . . . 1156
7.14.3 Cumulative product of array elements: numpy.cumprod . . . 1157
7.14.4 Cumulative sum of array elements: numpy.cumsum . . . 1157
7.14.5 N-th discrete difference: numpy.diff . . . 1158
7.14.6 Differences between consecutive elements: numpy.ediff1d . . . 1159
7.14.7 Gradient of an N-dimensional array: numpy.gradient . . . 1159
7.14.8 Trapezoidal rule: numpy.trapezoid . . . 1160
7.15 Numpy mathematical functions: Extrema Finding . . . 1162
7.15.1 Element-wise maximum of array elements: numpy.maximum . . . 1162
7.15.2 Element-wise minimum of array elements: numpy.minimum . . . 1162
7.15.3 Maximum of an array or maximum along an axis: numpy.max . . . 1162
7.15.4 Minimum of an array or maximum along an axis: numpy.min . . . 1163
7.16 Numpy mathematical functions: Arithmetic operations, elementwise . . . 1165
7.16.1 Numerical positive, element-wise: numpy.positive . . . 1165

7.16.2 Numerical negative, element-wise: numpy.negative 1165
7.16.3 Add arguments element-wise: numpy.add 1165
7.16.4 Subtract arguments element-wise: numpy.subtract 1166
7.16.5 Multiply arguments element-wise: numpy.multiply 1166
7.16.6 Divide arguments element-wise: numpy.divide 1166
7.16.7 Floor-divide arguments element-wise: numpy.floor_divide 1167
7.16.8 Element-wise remainder of division: numpy.remainder 1167
7.16.9 Element-wise square: numpy.square 1168
7.16.10 Element-wise reciprocal: numpy.reciprocal 1168
7.17 Numpy mathematical functions: Averages and variances 1169
7.17.1 Median of the array elements.: numpy.median 1169
7.17.2 Average of the array elements.: numpy.average 1169
7.17.3 Arithmetic mean: numpy.mean 1170
7.17.4 Variance: numpy.var 1171
7.18 Numpy mathematical functions: Matrix and vector products 1172
7.18.1 Dot product: numpy.dot 1172
7.18.2 Dot product of two vectors: numpy.vdot 1172
7.18.3 Inner product of two arrays: numpy.inner 1173
7.18.4 Outer product of two vectors: numpy.outer 1174
7.18.5 Matrix product of two arrays: numpy.matmul 1175
7.18.6 Tensor dot product: numpy.matmul 1176
7.18.7 Einstein summation: numpy.einsum 1177
7.18.8 Kronecker product: numpy.kron 1178
7.18.9 Discrete, linear convolution: numpy.convolve 1179
7.19 Numpy logical functions: Truth value testing 1181
7.19.1 Test whether all array elements evaluate to True.: numpy.all, ctx.all 1181
7.19.2 Test whether any array element evaluates to True: numpy.any, ctx.any 1181
7.19.3 Logical AND: numpy.logical_and, ctx.logical_and 1182
7.19.4 Logical OR: numpy.logical_or, ctx.logical_or 1182
7.19.5 Logical XOR: numpy.logical_xor, ctx.logical_xor 1183
7.19.6 Testing array equality: numpy.array_equal, ctx.array_equal 1183
7.19.7 Testing array array_equivalence: numpy.array_equiv, ctx.array_equiv 1184
7.19.8 Truth value of (x1 > x2) element-wise: numpy.greater, ctx.greater 1184
7.19.9 Truth value of (x1 >= x2) element-wise: numpy.greater_equal, ctx.greater_equal 1184
7.19.10 Truth value of (x1 < x2) element-wise: numpy.less, ctx.less 1185
7.19.11 Truth value of (x1 <= x2) element-wise: numpy.less_equal, ctx.less_equal 1185
7.19.12 Truth value of (x1 == x2) element-wise: numpy.equal, ctx.equal 1185
7.19.13 Truth value of (x1 != x2) element-wise: numpy.equal, ctx.equal 1186
7.20 Numpy mathematical functions: Integer and fractional 1187
7.20.1 Floor of the input, element-wise.: numpy.floor, ctx.floor 1187
7.20.2 Ceiling of the input, element-wise.: numpy.ceil, ctx.ceil 1187
7.20.3 Truncated value of the input, element-wise.: numpy.trunc, ctx.trunc 1188
7.20.4 Fix value of the input, element-wise.: numpy.fix, ctx.fix 1188
7.21 Numpy mathematical functions: Miscellaneous 1189
7.21.1 Random Generator 1189
7.21.2 Vectorization of a function: numpy.vectorize 1189
7.22 Summary and examples: Numpy utility functions 1191
7.22.1 Exact mathematical constants 1191
7.22.2 Complex components 1192
7.22.3 Array contents 1196
7.22.4 Array type testing 1201
7.22.5 Using tolerances 1204
7.22.6 Clipping (limiting) the values in an array. 1206
7.23 Arithmetic operations with scalars and iterables 1208

7.23.1 fadd: Addition using a custom precision and rounding mode . . . 1208
7.23.2 fsub: Subtraction using a custom precision and rounding mode . . . 1210
7.23.3 fneg: Negation of a number using a custom precision and rounding mode . . . 1210
7.23.4 fmul: Multiplication using a custom precision and rounding mode . . . 1211
7.23.5 fdiv: Division using a custom precision and rounding mode . . . 1212
7.23.6 fsum: Sum of a finite number of terms . . . 1213
7.23.7 fprod: Product of a finite number of factors . . . 1213
7.23.8 fdot: Dot product . . . 1213
7.24 Numerical transformations and descriptive statistics . . . 1215
7.24.1 Centering of a matrix . . . 1215
7.24.2 Standardization of a matrix . . . 1215
7.24.3 Trace . . . 1216
7.24.4 Squared Norm . . . 1216
7.24.5 Euclidian Norm . . . 1217
7.24.6 Covariance matrix . . . 1217
7.24.7 Correlation matrix . . . 1218
7.24.8 Summary statistic . . . 1218
7.24.9 Vector norm of a matrix . . . 1219
7.24.10 Matrix norm . . . 1220
7.25 Standard decompositions and linear solving . . . 1221
7.25.1 Cholesky decomposition . . . 1221
7.25.2 Cholesky decomposition, solve . . . 1222
7.25.3 Matrix LU factorization . . . 1222
7.25.4 Determinant of a matrix, using LU decomposition . . . 1222
7.25.5 Inverse of a matrix, using the LU factorization . . . 1222
7.25.6 Linear equations: LU solve . . . 1223
7.25.7 Linear equations: residual of LU solve . . . 1223
7.25.8 ??? LU improve solution . . . 1223
7.25.9 mpmath: LU condition number . . . 1223
7.25.10 QR factorization . . . 1224
7.25.11 QR solve . . . 1225
7.26 Singular Value and Eigen decompositions . . . 1226
7.26.1 Real singular value decomposition of a matrix A . . . 1226
7.26.2 Complex singular value decomposition of a matrix A . . . 1227
7.26.3 mpmath: Singular value decomposition of a matrix A (real or complex) . . . 1228
7.26.4 Eigenvalue problem for a real symmetric square matrix A . . . 1229
7.26.5 Eigenvalue problem for a complex hermitian square matrix A . . . 1230
7.26.6 mpmath: Eigenvalue problem for a selfadjoint square matrix A . . . 1231
7.26.7 mpmath: tridiag_sym . . . 1232
7.26.8 mpmath tridiag_her . . . 1233
7.26.9 mpmath: tridiag_eigen_sym . . . 1233
7.26.10 Eigensystem decomposition of a matrix A (real or complex) . . . 1234
7.26.11 Sorting Eigenvalues . . . 1235
7.26.12 mpmath: Hessenberg decomposition of a matrix A (real or complex) . . . 1235
7.26.13 Schur decomposition of a matrix A (real or complex) . . . 1236

II Special Functions 1238

8 Elliptic functions and related 1239
8.1 Carlson symmetric elliptic integrals . . . 1240
8.1.1 Carlson symmetric elliptic integral of the first kind, $R_F(x, y, z)$ . . . 1240
8.1.2 Carlson completely symmetric elliptic integral of the second kind, $R_G(x, y, z)$ . . . 1240
8.1.3 Carlson symmetric elliptic integral of the third kind, $R_J(x, y, z, p)$ . . . 1241

8.1.4 Carlson symmetric elliptic integral of the second kind, $R_D(x,y,z)$ . . . 1242
8.1.5 Carlson degenerate symmetric elliptic integral of the first kind, $R_C(x,y)$ . . . 1242
8.2 Legendre elliptic integrals (elliptic parameter m) . . . 1244
8.2.1 Legendre complete elliptic integral of the first kind, $K(m)$ . . . 1244
8.2.2 Legendre complete elliptic integral of the second kind, $E(m)$ . . . 1244
8.2.3 Legendre complete elliptic integral of the third kind, $\Pi(n,m)$ . . . 1245
8.2.4 Legendre incomplete elliptic integral of the first kind, $F(\phi,m)$ . . . 1246
8.2.5 Legendre incomplete elliptic integral of the second kind, $E(\phi,m)$ . . . 1247
8.2.6 Legendre incomplete elliptic integral of the third kind, $\Pi(n,\phi,m)$ . . . 1248
8.3 Legendre elliptic integrals (elliptic modulus k), and related functions . . . 1250
8.3.1 Legendre complete elliptic integral of the first kind, $K(k)$ . . . 1250
8.3.2 Legendre complete elliptic integral of the second kind, $E(k)$ . . . 1251
8.3.3 Legendre complete elliptic integral of the third kind, $\Pi(n;k)$ . . . 1252
8.3.4 Legendre incomplete elliptic integral of the first kind, $F(\phi,k)$ . . . 1253
8.3.5 Legendre incomplete elliptic integral of the second kind, $E(\phi,k)$ . . . 1253
8.3.6 Legendre incomplete elliptic integral of the third kind, $\Pi(n,\phi,k)$ . . . 1254
8.4 Jacobi elliptic functions . . . 1256
8.4.1 Jacobi elliptic function $\mathrm{sn}(x,k)$ . . . 1256
8.4.2 Jacobi elliptic function $\mathrm{cn}(x,k)$ . . . 1258
8.4.3 Jacobi elliptic function $\mathrm{dn}(x,k)$ . . . 1260
8.4.4 Jacobi elliptic function $\mathrm{nc}(x,k)$ . . . 1262
8.4.5 Jacobi elliptic function $\mathrm{sc}(x,k)$ . . . 1263
8.4.6 Jacobi elliptic function $\mathrm{dc}(x,k)$ . . . 1264
8.4.7 Jacobi elliptic function $\mathrm{nd}(x,k)$ . . . 1265
8.4.8 Jacobi elliptic function $\mathrm{sd}(x,k)$ . . . 1266
8.4.9 Jacobi elliptic function $\mathrm{cd}(x,k)$ . . . 1267
8.4.10 Jacobi elliptic function $\mathrm{ns}(x,k)$ . . . 1268
8.4.11 Jacobi elliptic function $\mathrm{cs}(x,k)$ . . . 1269
8.4.12 Jacobi elliptic function $\mathrm{ds}(x,k)$ . . . 1270
8.5 Jacobi theta functions and related functions . . . 1271
8.5.1 Jacobi theta function $\theta_1(z,q)$ . . . 1271
8.5.2 Jacobi theta function $\theta_2(z,q)$ . . . 1273
8.5.3 Jacobi theta function $\theta_3(z,q)$ . . . 1275
8.5.4 Jacobi theta function $\theta_4(z,q)$ . . . 1277
8.6 Conversions of parameters of Weierstrass $\wp$ . . . 1279
8.6.1 Elliptic lattice invariants g_2, g_3 from lattice roots e_1, e_2, e_3 . . . 1279
8.6.2 Elliptic lattice invariants g_2, g_3 from (ω, τ) . . . 1281
8.6.3 Elliptic lattice roots e_1, e_2, e_3 from (ω, τ) . . . 1282
8.7 Weierstrass elliptic functions, in terms of elliptic period ratio τ . . . 1284
8.7.1 Weierstrass function $\wp(z|\tau)$ . . . 1284
8.7.2 Weierstrass function, first derivative: $\wp' z|\tau)$ . . . 1284
8.7.3 Inverse Weierstrass function $\wp^{-1}(z|\tau)$ . . . 1285
8.7.4 Weierstrass Zeta function $\zeta(z,\tau)$ . . . 1286
8.7.5 Weierstrass Sigma function $\sigma(z|\tau)$ . . . 1287
8.8 Modular forms, in terms of half-period ω_1 and elliptic period ratio τ . . . 1288
8.8.1 Dedekind eta function $\eta(\tau)$ . . . 1288
8.8.2 Elliptic modular lambda function $\lambda(\tau)$ (also DAMath) . . . 1288
8.8.3 Elliptic modular delta function $\Delta(\omega,\tau)$ . . . 1289
8.8.4 Klein j-invariant $j(\tau)$ (also DAMath) . . . 1290

9 Lerch's phi and related **1291**
9.1 Lerch's transcendent and Lerch's zeta . . . 1292
9.1.1 Lerch's transcendent, $\Phi(x,s,a)$ . . . 1292
9.1.2 Lerch's zeta . . . 1295

9.2 Polygamma and related functions . . . 1296
9.2.1 Polygamma function, $\psi^{(n)}(x)$ . . . 1296
9.2.2 TriGamma function, $\psi'(x)$ . . . 1298
9.2.3 DiGamma function $\psi(x)$ . . . 1299
9.2.4 Harmonic number function, H_x . . . 1301
9.3 Polylogarithm and related functions . . . 1302
9.3.1 Polylogarithm, $\mathrm{Li}_s(z)$ . . . 1302
9.3.2 Trilogarithm Function, $\mathrm{Li}_3(z)$ . . . 1304
9.3.3 Dilogarithm Function, $\mathrm{Li}_2(z)$ . . . 1305
9.3.4 Generalized Clausen sine function . . . 1307
9.3.5 Generalized Clausen cosine function . . . 1309
9.3.6 Classical Clausen function, $\mathrm{Cl}_2(x)$ . . . 1310
9.3.7 Bose-Einstein integrals, $G_s(x)$ . . . 1311
9.3.8 Fermi-Dirac integrals, $F_s(x)$ . . . 1312
9.3.9 Legendre's Chi function, $\chi_s(x)$ . . . 1313
9.3.10 Generalized inverse tangent integral . . . 1315
9.4 Hurwitz zeta and related functions . . . 1316
9.4.1 Hurwitz zeta function, $\zeta(s, a)$ . . . 1316
9.4.2 Generalized harmonic number function, $H_x^{(r)}$ . . . 1318
9.4.3 Bernoulli numbers, B_n . . . 1319
9.4.4 Bernoulli polynomials, $B_n(x)$ . . . 1320
9.4.5 Euler numbers . . . 1321
9.4.6 Euler polynomials, $E_n(x)$ . . . 1322
9.4.7 Barnes G-function . . . 1323
9.4.8 Logarithm of Barnes G function . . . 1324
9.4.9 Hyperfactorial . . . 1325
9.4.10 Superfactorial . . . 1326
9.5 Riemann zeta function, and related functions . . . 1327
9.5.1 Riemann zeta function, $\zeta(s)$ . . . 1327
9.5.2 Riemann $\zeta(s) - 1$ . . . 1329
9.5.3 Hardy (or Riemann-Siegel) theta function . . . 1330
9.5.4 Hardy (or Riemann-Siegel) Z function . . . 1331
9.5.5 Riemann (Landau) function $\xi(s)$ . . . 1333
9.5.6 Dirichlet eta function, $\eta(s)$ . . . 1334
9.5.7 Dirichlet $\eta(s) - 1$ . . . 1335
9.5.8 Dirichlet beta function, $\beta(s)$ . . . 1336
9.5.9 Dirichlet lambda function, $\lambda(s)$ . . . 1337
9.5.10 Zeros of the Riemann zeta function . . . 1338

10 Hypergeometric function ${}_0F_1$ and related **1339**
10.1 Hypergeometric Limit Function ${}_0F_1$ . . . 1339
10.1.1 Confluent Hypergeometric Limit Function ${}_0F_1(b, x)$ . . . 1339
10.1.2 Regularized Confluent Hypergeometric Limit Function ${}_0\widetilde{F}_1(b; x)$ . . . 1341
10.2 Bessel functions . . . 1342
10.2.1 Bessel function of the 1st kind, $J_\nu(x)$ . . . 1342
10.2.2 Bessel function of the 2nd kind, $Y_\nu(x)$ . . . 1344
10.2.3 First derivative of the Bessel function of the first kind, $J'_\nu(x)$ . . . 1346
10.2.4 First derivative of the Bessel function of the second kind, $Y'_\nu(x)$ . . . 1347
10.2.5 Boost: Zeros $j_{\nu,m}$ of the Bessel function of the first kind: $J_\nu(j_{\nu,m}) = 0$ . . . 1348
10.2.6 Boost: Zeros $y_{\nu,m}$ of the Bessel function of the first kind: $Y_\nu(y_{\nu,m}) = 0$ . . . 1349
10.3 Modified Bessel functions . . . 1350
10.3.1 Modified Bessel function of the 1st kind, $I_\nu(x)$ . . . 1350
10.3.2 Modified Bessel function of the 2nd kind, $K_\nu(x)$ . . . 1352
10.3.3 First derivative of the modified Bessel function of the first kind $I'_\nu(x)$ . . . 1354

10.3.4 First derivative of the modified Bessel function of the second kind $K'_\nu(x)$ . . . 1355
10.3.5 Marcum Q function, $Q_m(a,b)$ (up to octuple precision) . . . 1356
10.4 Spherical Bessel functions . . . 1357
10.4.1 Spherical Bessel function of the first kind, $j_n(x)$ . . . 1357
10.4.2 Spherical Bessel function of the second kind, $y_n(x)$ . . . 1358
10.4.3 First derivative of the spherical Bessel function of the first kind, $j'_n(x)$ . . . 1359
10.4.4 First derivative of the spherical Bessel function of the second kind, $y'_n(x)$ . . . 1360
10.4.5 Boost: Zeros $a_{n,m}$ of the spherical Bessel function of the first kind: $j_n(a_{n,m}) = 0$ . . . 1361
10.4.6 Boost: Zeros $b_{n,m}$ of the spherical Bessel function of the second kind: $y_n(b_{n,m}) = 0$ . . . 1362
10.5 Modified spherical Bessel functions . . . 1363
10.5.1 Modified spherical Bessel function of the first kind, $i_n(x)$ . . . 1363
10.5.2 Modified Spherical Bessel function of the second kind, $k_n(x)$ . . . 1365
10.5.3 First derivative of the modified spherical Bessel function of the first kind, $i'_n(x)$ . . . 1366
10.5.4 First derivative of the modified spherical Bessel function of the second kind, $k'_n(x)$ . . . 1367
10.5.5 Bessel polynomials $y_n(x)$ . . . 1368
10.5.6 Reverse Bessel polynomials $\theta_n(x)$ . . . 1369
10.6 Hankel functions . . . 1370
10.6.1 Hankel function of the first kind $H_\nu^{(1)}(x)$ . . . 1370
10.6.2 Hankel function of the second kind $H_\nu^{(2)}(x)$ . . . 1371
10.6.3 Spherical Hankel function of the first kind, $h_\nu^{(1)}(x)$ . . . 1372
10.6.4 Spherical Hankel function of the second kind, $h_\nu^{(2)}(x)$ . . . 1373
10.7 Airy functions . . . 1374
10.7.1 Airy function $\mathrm{Ai}(x)$ . . . 1374
10.7.2 Airy function $\mathrm{Bi}(x)$ . . . 1376
10.7.3 First derivative of the Airy function Ai, $\mathrm{Ai}'(x)$ . . . 1378
10.7.4 First derivative of the Airy function Bi, $\mathrm{Bi}'(x)$ . . . 1379
10.7.5 Real zeros a_k of the Airy function Ai, $\mathrm{Ai}(a_k) = 0$ . . . 1380
10.7.6 Real zeros b_k of the Airy function Bi, $\mathrm{Bi}(b_k) = 0$ . . . 1381
10.8 Kelvin functions . . . 1382
10.8.1 Kelvin function $\mathrm{ber}(\nu, x)$ . . . 1382
10.8.2 Kelvin function $\mathrm{bei}(\nu, x)$ . . . 1383
10.8.3 Kelvin function $\mathrm{ker}(\nu, x)$ . . . 1384
10.8.4 Kelvin function $\mathrm{kei}(\nu, x)$ . . . 1385
10.8.5 First derivative of the Kelvin function $\mathrm{ber}(\nu, x)$, $\mathrm{ber}'(\nu, x)$ . . . 1386
10.8.6 First derivative of the Kelvin function $\mathrm{bei}(\nu, x)$, $\mathrm{bei}'(\nu, x)$ . . . 1387
10.8.7 First derivative of the Kelvin function $\mathrm{ker}(\nu, x)$, $\mathrm{ker}'(\nu, x)$ . . . 1388
10.8.8 First derivative of the Kelvin function $\mathrm{kei}(\nu, x)$, $\mathrm{kei}'(\nu, x)$ . . . 1389

11 Hypergeometric function ${}_1F_1$ and related **1390**
11.1 Hypergeometric Functions ${}_1F_1$ (Kummer) and U (Tricomi) . . . 1390
11.1.1 Kummer's Confluent Hypergeometric Function ${}_1F_1(a,b;x)$ . . . 1390
11.1.2 Regularized Kummer Confluent Hypergeometric Function, ${}_1\widetilde{F}_1(a,b;x)$ . . . 1392
11.1.3 Tricomi's Confluent Hypergeometric Function, $U(a,b;x)$ . . . 1393
11.1.4 Generalized Laguerre polynomials, $L_n^{(a)}(x)$ . . . 1395
11.1.5 Hermite polynomial (physicist), $H_n(x)$ . . . 1396
11.1.6 Hermite polynomials (probabilist) $\mathrm{He}_n(x)$ . . . 1397
11.2 Incomplete gamma functions . . . 1398
11.2.1 Lower normalized incomplete gamma function, $P(a,x)$ . . . 1398
11.2.2 Upper normalized incomplete gamma functions , $Q(a,x)$ . . . 1399
11.2.3 Lower non-normalized incomplete gamma function, $\gamma(a,x)$ . . . 1401
11.2.4 Upper non-normalized incomplete gamma function, $\Gamma(a,x)$ . . . 1402
11.2.5 Tricomi's entire incomplete gamma function: $\gamma^*(a,x)$ . . . 1403
11.2.6 Derivative of the incomplete gamma function . . . 1404

11.2.7 Inverse of the real lower normalised incomplete gamma function, $P^{-1}(a,q)$ . . . 1404
11.2.8 Inverse of the real upper normalised incomplete gamma function, $Q^{-1}(a,q)$ . . . 1405
11.2.9 Inverse (on parameter a) of the real lower normalised incomplete gamma function . . . 1405
11.2.10 Inverse (on parameter a) of the real upper normalised incomplete gamma function . . . 1405
11.3 Coulomb, Whittaker and parabolic cylinder function . . . 1407
11.3.1 Regular Coulomb wave function $F_\ell(\eta,x)$ . . . 1407
11.3.2 Irregular Coulomb wave function $G_\ell(\eta,z)$ . . . 1408
11.3.3 Irregular Coulomb wave function $H_\ell^{(+)}(\eta,x)$ . . . 1409
11.3.4 Irregular Coulomb wave function $H_\ell^{(-)}(\eta,x)$ . . . 1410
11.3.5 Whittaker function $M_{\kappa,\mu}(x)$ . . . 1411
11.3.6 Whittaker function $W_{\kappa,\mu}(x)$ . . . 1412
11.3.7 Parabolic cylinder function $D_\nu(x)$ . . . 1413
11.3.8 Parabolic cylinder function $U(a,x)$ . . . 1414
11.3.9 Parabolic cylinder function $V(a,x)$ . . . 1415
11.3.10 Parabolic cylinder function $W(a,x)$ . . . 1416
11.4 Error function and related functions . . . 1417
11.4.1 Error function, $\mathrm{erf}(x)$ . . . 1417
11.4.2 Complementary error function, $\mathrm{erfc}(x)$ . . . 1419
11.4.3 Inverse of the real error function, $\mathrm{erf}^{-1}(x)$ . . . 1421
11.4.4 Inverse of the real complementory error function, $\mathrm{erfc}^{-1}(x)$ . . . 1422
11.4.5 Standard normal density function $\phi(x)$ . . . 1423
11.4.6 Standard normal cumulative distribution function $\Phi(x)$ . . . 1424
11.4.7 Standard normal quantile function $\Phi^{-1}(q)$ . . . 1424
11.4.8 Imaginary error function, $\mathrm{erfi}(x)$ . . . 1425
11.4.9 Dawson integral, $F(x)$ . . . 1426
11.4.10 Faddeeva function, $w(z)$ . . . 1427
11.4.11 Fresnel sine integral, $S(x)$ . . . 1428
11.4.12 Fresnel cosine integral, $C(x)$ . . . 1430
11.4.13 Owen's T function, $T(h,a)$ . . . 1432
11.5 Exponential integrals, and related functions . . . 1433
11.5.1 Exponential integral $E_1(x)$ . . . 1433
11.5.2 Exponential integral $\mathrm{Ei}(x)$ . . . 1434
11.5.3 Logarithmic integral $\mathrm{li}(x)$ . . . 1436
11.5.4 Hyperbolic sine integral $\mathrm{Shi}(x)$ . . . 1438
11.5.5 Hyperbolic cosine integral $\mathrm{Chi}(x)$ . . . 1439
11.5.6 Generalized exponential integral $E_n(x)$ . . . 1440
11.5.7 Sine integral $\mathrm{Si}(x)$ . . . 1441
11.5.8 Cosine integral $\mathrm{Ci}(x)$ . . . 1443

12 Hypergeometric functions ${}_2F_1$ and ${}_1F_2$ (and related functions) 1445
12.1 Gauss Hypergeometric Function ${}_2F_1$ . . . 1445
12.1.1 Gauss Hypergeometric Function, ${}_2F_1(a,b;c;x)$ . . . 1445
12.1.2 Regularized Hypergeometric Function, ${}_2\widetilde{F}_1(a,b;c;x)$ . . . 1447
12.2 Chebyshev, Gegenbauer and Jacobi polynomials . . . 1448
12.2.1 Chebyshev polynomial (or function) of the first kind, $T_n(x)$ . . . 1448
12.2.2 Chebyshev polynomial of the second kind, $U_n(x)$ . . . 1449
12.2.3 Chebyshev polynomials of the third kind, $V_n(x)$ . . . 1450
12.2.4 Chebyshev polynomials of the fourth kind, $W_n(x)$ . . . 1451
12.2.5 Gegenbauer (ultraspherical) polynomial, $C_n^\alpha(x)$ . . . 1452
12.2.6 Jacobi polynomials, $P_n^{(a,b)}(x)$ . . . 1453
12.2.7 Zernike radial polynomials $R_n^m(r)$ . . . 1455
12.3 Legendre polynomials and related . . . 1456
12.3.1 Legendre polynomial (or function) of the first kind, $P_n(x)$ . . . 1456

12.3.2 Associated Legendre function of the first kind, $P_l^m(x)$ . . . 1457
12.3.3 Legendre function of the second kind, $Q_l(x)$ . . . 1458
12.3.4 Associated Legendre function of the second kind, $Q_l^m(x)$ . . . 1459
12.3.5 Spherical harmonics, $Y_n^m(\theta,\phi)$ . . . 1460
12.3.6 Toroidal harmonics $P^m_{l-1/2}(x)$ . . . 1460
12.3.7 Toroidal harmonics $Q^m_{l-1/2}(x)$ . . . 1461
12.4 Incomplete beta functions . . . 1462
12.4.1 Non-normalized lower incomplete beta function, $B_{\text{lower}}(a,b;x)$ . . . 1462
12.4.2 Normalized incomplete beta function, $I_x(a,b)$ . . . 1463
12.4.3 Derivative of the incomplete beta function . . . 1465
12.4.4 Real non-normalized upper incomplete beta function, $B_{\text{upper}}(a,b;x)$ . . . 1466
12.4.5 Real normalized complementory incomplete beta function, $I_{1-x}(a,b)$ . . . 1467
12.4.6 Inverse of the real normalised incomplete beta function . . . 1469
12.4.7 Inverse of the real normalised complementary incomplete beta function . . . 1470
12.4.8 Inverse (on parameter a) of the real normalised incomplete beta function . . . 1471
12.4.9 Inverse (on parameter a) of the real normalised complementary incomplete beta function . . . 1472
12.4.10 Inverse (on parameter b) of the real normalised incomplete beta function . . . 1473
12.4.11 Inverse (on parameter b) of the real normalised complementary incomplete beta function . . . 1474
12.5 Hypergeometric function ${}_1F_2$ . . . 1475
12.5.1 Non-regularized hypergeometric function ${}_1F_2$ . . . 1475
12.5.2 Regularized hypergeometric function ${}_1\widetilde{F}_2$ . . . 1476
12.6 Scorer functions . . . 1477
12.6.1 Scorer function $\mathrm{Gi}(x)$ . . . 1477
12.6.2 Scorer function $\mathrm{Hi}(x)$ . . . 1478
12.6.3 First derivative of the Scorer function $\mathrm{Gi}(x)$, $\mathrm{Gi}'(x)$ . . . 1479
12.6.4 First derivative of the Scorer function $\mathrm{Hi}(x)$, $\mathrm{Hi}'(x)$ . . . 1480
12.7 Struve functions . . . 1481
12.7.1 Struve function $\mathbf{H}_n(x)$ . . . 1481
12.7.2 Struve function $\mathbf{L}_\nu(x)$ . . . 1482
12.7.3 Struve function $\mathbf{K}_\nu(x)$ . . . 1483
12.7.4 Struve function $\mathbf{M}_\nu(x)$ . . . 1484
12.8 Anger, Weber and Lommel functions . . . 1485
12.8.1 Anger function $\mathbf{J}_\nu(x)$ . . . 1485
12.8.2 Weber function $\mathbf{E}_\nu(x)$ . . . 1486
12.8.3 Lommel function $s_{\mu,\nu}(x) = s^{(1)}_{\mu,\nu}(x)$ . . . 1487
12.8.4 Lommel function $S_{\mu,\nu}(x) = s^{(2)}_{\mu,\nu}(x)$ . . . 1488

III Supporting Functions **1489**

13 Algebra with random variables **1490**
13.1 Probability density function (pdf) . . . 1490
13.1.1 Calculating the pdf from the cdf . . . 1490
13.1.2 Calculating the pdf from the characteristic function . . . 1490
13.2 Probability mass function (pmf) . . . 1491
13.2.1 Calculating the pmf from the cdf . . . 1491
13.2.2 Calculating the pmf from the characteristic function . . . 1491
13.2.3 Calculating the pmf from the factorial moments . . . 1491
13.2.4 Approximating the pmf with asymptotic expansions . . . 1491
13.3 Cumulative distribution function (cdf) . . . 1492
13.3.1 Calculating the cdf from the pdf . . . 1492
13.3.2 Calculating the cdf from the pmf . . . 1492
13.3.3 Calculating the cdf from the characteristic function . . . 1492
13.3.4 Calculating the cdf and sf from the characteristic function (lattice distribution) . . . 1494

13.3.5 Calculating the cdf from the factorial moments (lattice distributions) . . . 1494
13.4 Quantile function . . . 1495
13.4.1 Calculating the quantile function from the cdf . . . 1495
13.4.2 Approximating the quantile function from the cumulant generating function . . . 1495
13.4.3 Approximating the quantile function from the cumulants . . . 1495
13.5 Characteristic function . . . 1496
13.5.1 Calculating the characteristic function from the pdf (continuous distribution) . . . 1496
13.5.2 Calculating the characteristic function from the pmf (lattice distribution) . . . 1496
13.5.3 Calculating the characteristic function from the quantile function . . . 1496
13.5.4 Calculating the characteristic function from the raw moments . . . 1496
13.6 Moment generating function . . . 1497
13.6.1 Calculating the moment-generating function from the pdf . . . 1497
13.6.2 Calculating the moment-generating function from the characteristic function . . . 1497
13.6.3 Calculating the moment-generating function from the cumulant-generating function . . . 1497
13.6.4 Calculating the moment-generating function from the probability-generating function . . . 1497
13.6.5 Calculating the moment-generating function from the raw moments . . . 1497
13.7 Cumulant generating function . . . 1498
13.7.1 Calculating the cumulant-generating function from the characteristic function . . . 1498
13.7.2 Calculating the cumulant-generating function from the moment-generating function . . . 1498
13.7.3 Calculating the cumulant-generating function from the probability-generating function . . . 1498
13.7.4 Calculating the cumulant-generating function from the cumulants . . . 1498
13.8 Probability generating function . . . 1499
13.8.1 Calculating the probability-generating function from the pmf vector . . . 1499
13.8.2 Calculating the probability-generating function from the moment-generating function . . . 1499
13.9 Factorial Moments . . . 1500
13.9.1 Calculating the factorial moments from the raw moments . . . 1500
13.9.2 Calculating the factorial moments from the cumulants . . . 1500
13.10 Raw Moments . . . 1501
13.10.1 Calculating the raw moments from the pdf . . . 1501
13.10.2 Calculating the raw moments from the pmf . . . 1501
13.10.3 Calculating the raw moments from the factorial moments . . . 1501
13.10.4 Calculating the raw moments from the central moments . . . 1501
13.10.5 Calculating the raw moments from the cumulants . . . 1502
13.10.6 Calculating the raw moments from the moment-generating function . . . 1502
13.10.7 Calculating the raw moments from the characteristic function . . . 1502
13.10.8 Calculating the raw moments from the probability-generating function . . . 1502
13.11 Central Moments . . . 1503
13.11.1 Calculating the central moments from the factorial moments . . . 1503
13.11.2 Calculating the central moments from the raw moments . . . 1503
13.11.3 Calculating the central moments from the cumulants . . . 1503
13.12 Cumulants . . . 1504
13.12.1 Calculating the cumulants from the pmf vector . . . 1504
13.12.2 Calculating the cumulants from the factorial moments . . . 1504
13.12.3 Calculating the cumulants from the raw moments . . . 1504
13.12.4 Calculating the cumulants from the central moments . . . 1504
13.12.5 Calculating the cumulants from the cumulant-generating function . . . 1504

14 Series and integrals **1506**
14.1 Finite series algorithms for selected distributions . . . 1506
14.1.1 Central χ^2 distribution, cdf (integer degrees of freedom) . . . 1506
14.1.2 Central Student t distribution, cdf (integer degrees of freedom) . . . 1506
14.1.3 Central Fisher F distribution, cdf (integer degrees of freedom) . . . 1507
14.1.4 Central Beta distribution, cdf ($2a$ an integer, $2b$ an integer) . . . 1508
14.1.5 Noncentral χ^2 distribution, cdf (integer degrees of freedom) . . . 1508

14.1.6 Noncentral Student t distribution, cdf (integer degrees of freedom) . . . 1509
14.1.7 Noncentral Fisher F distribution, cdf (m an even integer) . . . 1509
14.1.8 Noncentral Beta distribution, cdf (b an integer) . . . 1510
14.1.9 Pearson's ρ distribution, pdf (integer N) . . . 1510
14.1.10 Pearson's ρ distribution, cdf (integer N) . . . 1511
14.1.11 Fisher's R^2 distribution, cdf (finite sum for $N - p$ even) . . . 1512
14.1.12 Roy's largest root distribution, pdf, cdf and sf . . . 1513
14.2 Infinite series algorithms for selected functions and distributions . . . 1515
14.2.1 Incomplete gamma function, continued fractions (Peizer) . . . 1515
14.2.2 Incomplete gamma function, asymptotic expansion (Paris) . . . 1516
14.2.3 Incomplete beta function, continued fractions (Peizer) . . . 1516
14.2.4 Noncentral χ^2 distribution, pdf, cdf and sf (Boost) . . . 1517
14.2.5 Noncentral Student t distribution, pdf, cdf and sf (Boost) . . . 1518
14.2.6 Noncentral Beta distribution, pdf, cdf and sf (Boost) . . . 1519
14.2.7 Noncentral F distribution, pdf, cdf and sf (Benton) . . . 1519
14.2.8 Pearson's ρ distribution, cdf and sf (Hotelling's series) . . . 1520
14.2.9 Pearson's ρ distribution, cdf and sf (Guenther's series) . . . 1521
14.2.10 Fisher's R^2 distribution, cdf and sf (Boost, Benton) . . . 1522
14.3 Finite series for lattice distributions, based on factorial moments . . . 1523
14.3.1 Fréchet's formula for calculating the pmf from the factorial moments . . . 1523
14.3.2 Laurent's formula for calculating the cdf from the factorial moments . . . 1523
14.3.3 Binomial distribution, pmf, cdf . . . 1524
14.3.4 Classical hypergeometric distribution, pmf, cdf . . . 1524
14.3.5 Wilcoxon distribution, pmf, cdf . . . 1525
14.3.6 Mann-Whitney distribution, pmf, cdf . . . 1526
14.3.7 Kendall distribution, pmf, cdf . . . 1527
14.3.8 Jonckheere-Terpsta T distribution, pmf, cdf . . . 1527
14.4 Efficient integration of bell-shaped functions . . . 1529
14.4.1 Introduction . . . 1529
14.4.2 Error function . . . 1529
14.4.3 Lower non-normalised incomplete gamma function, $\gamma(a, x)$ (Continued fractions) . . . 1529
14.4.4 Real upper non-normalised incomplete gamma function, $\Gamma(a, x)$ (Quadrature) . . . 1529
14.4.5 Normalised incomplete beta function, $I_x(a, b)$ . . . 1530
14.4.6 Non-central chi-square cdf and sf (Chow) . . . 1530
14.4.7 Marcum Q function . . . 1530
14.4.8 Owen's T function . . . 1531
14.5 Verified numerical integration . . . 1533
14.5.1 Error function . . . 1533
14.5.2 Lower non-normalised incomplete gamma function, $\gamma(a, x)$ (Continued fractions) . . . 1533
14.5.3 Real upper non-normalised incomplete gamma function, $\Gamma(a, x)$ (Quadrature) . . . 1533
14.5.4 Normalised incomplete beta function, $I_x(a, b)$ . . . 1533
14.5.5 Non-central chi-square cdf and sf (Chow) . . . 1534
14.5.6 Marcum Q function . . . 1534
14.5.7 Owen's T function . . . 1535

15 Pmf vectors **1537**
15.1 Basic discrete (lattice) distribution functions . . . 1537
15.1.1 Poisson distribution, pmf vector . . . 1537
15.1.2 Binomial distribution, pmf vector . . . 1537
15.1.3 Negative binomial distribution, pmf vector . . . 1538
15.1.4 Hypergeometric distribution, pmf vector . . . 1538
15.1.5 Noncentral hypergeometric distribution (Fisher), pmf vector . . . 1538
15.2 Discrete (lattice) distribution functions related to (stratified) rank tests . . . 1540
15.2.1 Sign test distribution (under H_0), pmf vector . . . 1540

15.2.2 Wilcoxon T distribution (under H_0), pmf vector . . . 1540
15.2.3 Wilcoxon T distribution (under Bennett alternatives), pmf vector . . . 1540
15.2.4 Kendall S (or tau) distribution (under H_0), pmf vector . . . 1540
15.2.5 Mann-Whitney U distribution (under H_0), pmf vector . . . 1541
15.2.6 Jonckheere-Terpsta S distribution (under H_0), pmf vector . . . 1541
15.2.7 Spearman ρ distribution (under H_0), pmf vector . . . 1541
15.2.8 Page L distribution (under H_0), pmf vector . . . 1542
15.2.9 Quade L distribution (under H_0), pmf vector . . . 1542
15.2.10 Mann-Whitney U distribution (under Lehmann alternatives), pmf vector . . . 1542
15.2.11 Mann-Whitney U distribution (under Milton alternatives), pmf vector . . . 1543
15.3 Discrete (non-lattice) distribution functions related to rank tests . . . 1544
15.3.1 Cochran S distribution (under H_0), pmf vector . . . 1544
15.3.2 Friedman S distribution (under H_0), pmf vector . . . 1544
15.3.3 Quade S distribution (under H_0), pmf vector . . . 1544
15.3.4 Kruskal-Wallis H distribution (under H_0), pmf vector . . . 1545

16 Fast approximations **1546**
16.1 Approximations based on the normal distribution . . . 1546
16.1.1 Non-central chi-squared distribution: cdf and sf (Penev) . . . 1546
16.1.2 (Non-central) chi-squared distribution: qtf and isf (Canal) . . . 1546
16.1.3 Gamma distribution: qtf and isf (Canal) . . . 1547
16.1.4 F distribution: qtf and isf (Davis) . . . 1548
16.1.5 Beta distribution: qtf and isf (Davis) . . . 1548
16.1.6 Pearson's rho distribution: pdf (Winterbottom) . . . 1549
16.1.7 Pearson's rho distribution: cdf and sf (Winterbottom) . . . 1549
16.1.8 Pearson's rho distribution: qtf and isf (Winterbottom) . . . 1549
16.1.9 Pearson's rho distribution: confidence limit for ρ (Winterbottom) . . . 1550
16.1.10 Singly noncentral t: pdf (Broda) . . . 1551
16.1.11 Singly noncentral t: cdf, sf (Broda) . . . 1551
16.1.12 Singly noncentral t: qtf, isf (Harley) . . . 1552
16.1.13 Singly noncentral t: confidence limit for δ (Akahira) . . . 1552
16.1.14 Doubly noncentral t: cdf, sf (Broda) . . . 1553
16.1.15 Doubly noncentral t: qtf, isf (Broda) . . . 1554
16.1.16 Spearman's rho, first 8 cumulants (David) . . . 1554
16.1.17 Mann-Whitney U distribution: general alternatives specified by rank order probabilities (Sundrum) . . . 1555
16.1.18 First 4 moments of Kendalls τ in the general case (Sundrum) . . . 1557
16.2 Approximations based on the chi-squared distribution . . . 1559
16.2.1 Non-Central chi-squared : cdf, sf (Patnaik) . . . 1559
16.2.2 Non-Central chi-squared: qtf, isf (Patnaik) . . . 1559
16.2.3 Non-Central chi-squared: confidence limit for λ (Winterbottom) . . . 1559
16.2.4 Roy's largest root θ: pdf (Chiani) . . . 1560
16.2.5 Roy's largest root: cdf and sf (Chiani) . . . 1561
16.2.6 Roy's largest root: qtf and isf (Chiani) . . . 1562
16.3 Approximations based on the central t, F or beta distribution . . . 1563
16.3.1 Dunn-Šidák percentage points . . . 1563
16.3.2 Singly non-central Fisher F distribution: cdf, sf (Patnaik) . . . 1563
16.3.3 Singly non-central F distribution: qtf, isf (Patnaik) . . . 1564
16.3.4 Singly non-central F: confidence interval for the noncentrality parameter λ . . . 1564
16.3.5 Doubly non-central F distribution: cdf, sf (Patnaik) . . . 1564
16.3.6 Doubly non-central F distribution: qtf, isf (Patnaik) . . . 1565
16.3.7 Multiple correlation coefficient: cdf, sf (Lee and Gurland) . . . 1566
16.3.8 Multiple correlation coefficient: qtf, isf (Lee and Gurland) . . . 1566
16.3.9 Fisher R^2,: confidence limit for ρ^2 . . . 1566
16.3.10 Central Wilks' Lambda: cdf, sf (Rao) . . . 1568

16.3.11 Central Wilks' Lambda: qtf, isf (Rao) . . . 1568
16.3.12 Central Hotelling's T^2: cdf, sf (Pillai and Young) . . . 1569
16.3.13 Central Hotelling's T^2: qtf, isf (Pillai and Young) . . . 1569
16.3.14 Central Pillai's V: cdf, sf (Ginzberg) . . . 1570
16.3.15 Central Pillai's V: qtf, isf (Ginzberg) . . . 1570
16.3.16 Product of independent beta variables: cdf, sf (Nagarsenker) . . . 1571
16.3.17 Product of independent beta variables: qtf, isf (Nagarsenker) . . . 1571
16.4 Approximations based on the noncentral chi-squared distribution . . . 1573
16.4.1 Non-central Wilks' Lambda (GLM): cdf and sf (Fujikoshi) . . . 1573
16.4.2 Non-central Wilks' Lambda (independence): cdf and sf (Lee) . . . 1575
16.4.3 Non-central Pillai's V (GLM): cdf and sf Fujikoshi . . . 1576
16.4.4 Non-central Pillai's V (independence): cdf and sf (Lee) . . . 1577
16.4.5 Non-central Hotelling T^2 (GLM): cdf and sf (Fujikoshi) . . . 1578
16.4.6 Non-central Hotelling T^2 (independence): cdf and sf (Lee) . . . 1579
16.5 Approximations based on the noncentral F or beta distribution . . . 1581
16.5.1 Multiple correlation coefficient (Lee and Gurland) . . . 1581
16.5.2 Noncentral Wilks' Lambda under the GLM alternative . . . 1581
16.5.3 Noncentral Wilks' Lambda under the independence alternative . . . 1581
16.5.4 Noncentral Hotelling's T under the GLM alternative . . . 1582
16.5.5 Noncentral Hotelling's T under the independence alternative . . . 1582
16.5.6 Noncentral Pillai's V under the GLM alternative . . . 1583
16.5.7 Noncentral Pillai's V under the independence alternative . . . 1583
16.5.8 Noncentral Roy's largest root under the GLM alternative . . . 1583
16.5.9 Noncentral Roy's largest root under the independence alternative . . . 1584
16.6 Approximations based on hypergeometric functions of scalar argument . . . 1585
16.6.1 Hypergeometric function ${}_1F_1$ for matrix argument (Butler's approximation) . . . 1585
16.6.2 Comparisons with MATLAB: some results . . . 1585
16.6.3 Hypergeometric function ${}_2F_1$ for matrix argument (Butler's approximation) . . . 1586
16.6.4 Comparison with MATLAB: some results . . . 1586

IV Gallery of Plots **1587**

17 Visualisation of datasets **1588**
17.1 Bar Charts . . . 1589
17.1.1 Bar chart, part 1 . . . 1589
17.1.2 Bar chart, part 2 . . . 1590
17.1.3 Stacked Bar Plot . . . 1591
17.1.4 Grouped Bar Plot . . . 1592
17.1.5 Grouped StackedBar Plot . . . 1593
17.1.6 Barplot with error bar . . . 1594
17.1.7 Waterfall Plot . . . 1595
17.1.8 Mirror Histogram . . . 1596
17.1.9 Horizontal Bar . . . 1597
17.1.10 Horizontal Error Bar . . . 1598
17.1.11 Stacked horizontal bar with labels . . . 1599
17.1.12 Stacked and grouped horizontal bar . . . 1600
17.1.13 Gantt Chart . . . 1601
17.1.14 Marketing Funnel . . . 1602
17.1.15 Population Pyramid . . . 1603
17.1.16 Mirror Bar Plot (horizontal) . . . 1604
17.1.17 Tornado Chart . . . 1605
17.1.18 Circular Barplot . . . 1606
17.1.19 Barplot with color . . . 1607

17.2 Line and lollipop charts . . . 1608
17.2.1 Line chart (Seaborn) . . . 1608
17.2.2 Slope Chart . . . 1609
17.2.3 Line chart with error Bar . . . 1610
17.2.4 Confidence band (RandomWalk) . . . 1611
17.2.5 Plotting Parallel (Pandas) . . . 1612
17.2.6 Andrew Curves (Pandas) . . . 1613
17.2.7 Highlighted LinePlot . . . 1614
17.2.8 Multiple Lines And Panels . . . 1615
17.2.9 Line chart with fancy formatting . . . 1616
17.2.10 Lolllipop 2 Groups . . . 1617
17.2.11 Highlight Group In Lollipop . . . 1618
17.2.12 Lolllipop Conditional Color . . . 1619
17.2.13 Lollipop chart with fancy formatting . . . 1620
17.2.14 Circular Lolllipop . . . 1621
17.3 Area Plots . . . 1623
17.3.1 Percentage Stacked Area Chart . . . 1623
17.3.2 StackedAreaChart1 . . . 1624
17.3.3 Steam graph . . . 1626
17.3.4 Area Chart . . . 1627
17.3.5 Density Chart . . . 1628
17.3.6 Ridgetline Plot . . . 1629
17.3.7 Kde Plot, 3 versions . . . 1630
17.4 Boxplot, Violinplot and Raincloud plot . . . 1633
17.4.1 Boxplot, simple . . . 1633
17.4.2 Boxplot, multiple groups . . . 1634
17.4.3 ViolinPlot . . . 1635
17.4.4 Boxplot vs violinplot . . . 1636
17.4.5 Boxenplot . . . 1637
17.4.6 Swarmplot . . . 1638
17.4.7 Stripplot . . . 1639
17.4.8 Catplot . . . 1640
17.4.9 Raincloud Plot . . . 1641
17.5 Correlation and regression . . . 1642
17.5.1 Linear regression with confidence Band . . . 1642
17.5.2 Anscombe example . . . 1643
17.5.3 Faceted Scatter Plots: all in one plot . . . 1644
17.5.4 Faceted Scatter Plots: separate plots . . . 1645
17.5.5 Faceted Scatter Plots: further subgrouping . . . 1646
17.5.6 Bubbleplot . . . 1647
17.5.7 Scatterplot with fancy formatting . . . 1648
17.5.8 Scatterplots with positive, negative and weak correlation: confidence ellipses . . . 1649
17.5.9 Scatterplot with confidence confidence ellipses at different standard deviations . . . 1650
17.5.10 Hexagonal binned plot and marginal histograms (Seaborn) . . . 1651
17.5.11 Joint and marginal Kde (Seaborn) . . . 1652
17.5.12 Marginal ticks . . . 1653
17.5.13 Regression_marginals (Seaborn) . . . 1654
17.5.14 Pair grid with kde (Seaborn) . . . 1655
17.5.15 Scatterplot matrix (Seaborn) . . . 1656
17.6 Financial plots (requires mplfinance) . . . 1657
17.6.1 HiLoPlot . . . 1657
17.6.2 CandlePlot . . . 1658
17.6.3 LinePlot . . . 1659
17.6.4 RenkoPlot . . . 1660

17.6.5 PnfPlot . . . 1661
17.6.6 OhlcMav4Plot . . . 1662
17.6.7 CandleMav369Plot . . . 1663
17.6.8 CandleMav369VolPlot . . . 1664
17.6.9 CandleMav369VolNonTradPlot . . . 1665
17.7 Geographic data (requires cartopy) . . . 1666
17.7.1 Antarctis . . . 1666
17.7.2 Australia . . . 1667
17.7.3 Africa . . . 1668
17.7.4 World Flight . . . 1669
17.7.5 World Night Shading . . . 1670
17.7.6 World2projections . . . 1671
17.7.7 Country population estimates . . . 1672
17.7.8 Arctis and Antarctis . . . 1673
17.7.9 Geographic Mapping, with longitude and altitude on 4 axes crs=ccrs.PlateCarree . . . 1674
17.7.10 Geographic Mapping, World, projection=ccrs.InterruptedGoodeHomolosine . . . 1675
17.7.11 Geographic Mapping, World, projection=ccrs.PlateCarree . . . 1676
17.7.12 Labelling projection axes: PlateCarree and Mercator . . . 1677
17.8 Geographic data (requires geopandas) . . . 1678
17.8.1 World Happiness Report 2019 . . . 1678
17.8.2 World Happiness Report 2019: Europe . . . 1679
17.8.3 US state populations . . . 1680
17.8.4 California . . . 1681
17.8.5 Berlin, Esda . . . 1682
17.8.6 New York, Collisions . . . 1683
17.8.7 New York, Tickets . . . 1684
17.8.8 New York, Factors . . . 1685
17.8.9 Europe CO2 Emissions . . . 1686

17.9.1 Waffle Chart . . . 1690
17.9.2 Pie Chart . . . 1691
17.9.3 Donut Chart . . . 1692
17.9.4 Radar Chart . . . 1693
17.9.5 Venn Diagram . . . 1694
17.9.6 Treemap . . . 1695
17.10 Dendrograms, heatmaps and clustermaps . . . 1696
17.10.1 Dendrogram . . . 1696
17.10.2 Heatmap, simple . . . 1699
17.10.3 Heatmap, complex . . . 1700
17.10.4 Matshow . . . 1701
17.10.5 Many pairwise correlations (Seaborn) . . . 1702
17.10.6 Structured heatmap (Seaborn) . . . 1703
17.10.7 Clustermap (Seaborn) . . . 1704
17.11 PlotTable . . . 1705
17.11.1 PlotTable1 . . . 1705
17.11.2 PlotTable2 . . . 1706
17.11.3 PlotTable3 . . . 1707
17.11.4 PlotTable4 . . . 1708
17.11.5 PlotTable5 . . . 1709
17.12 Flow and connections . . . 1710
17.12.1 Sankey Default . . . 1710

17.12.2 Sankey 2 Systems . . . 1711
17.12.3 Sankey Rankine . . . 1712
17.12.4 Sankey One 2 one . . . 1713
17.12.5 Sankey Flow . . . 1714
17.12.6 Arcplot . . . 1715
17.12.7 Funnel Chart . . . 1716
17.13 Circular plots and flows . . . 1717
17.13.1 Circular track plotting . . . 1717
17.13.2 Circular heatmap . . . 1718
17.13.3 Chord diagram (matrix 3x6) . . . 1719
17.13.4 Chord diagram (matrix10x10) . . . 1720
17.13.5 Chord diagram (from-to table) . . . 1721
17.13.6 Circos plot: genom of a phage . . . 1722
17.13.7 Circos plot: genom of homo sapiens . . . 1723
17.13.8 Circos plot: chromosome links . . . 1724
17.13.9 Philogenetic tree: bars . . . 1725
17.13.10 Philogenetic tree: heatmap . . . 1726
17.14 Network data (requires networkx) . . . 1727
17.14.1 Multipartite_Layout . . . 1727
17.14.2 Rainbow_Coloring . . . 1728
17.14.3 Random_Geometry . . . 1729
17.14.4 Travelling_Salesman . . . 1730
17.14.5 NapoleonRussianCampaign . . . 1731
17.14.6 Community Visualisation . . . 1732
17.14.7 Connected Components . . . 1733

18 Visualisation of functions and curves (2D) 1734
18.1 Introduction to 2D functions plots . . . 1734
18.1.1 Simple plot of (well-behaved) functions in 2D . . . 1734
18.1.2 Function plots on different scales . . . 1735
18.1.3 Stepplot . . . 1736
18.1.4 Stemplot . . . 1737
18.1.5 Histograms and densities . . . 1738
18.1.6 Cumulative histogram and CDF . . . 1739
18.1.7 Plots of continuous distribution functions . . . 1740
18.1.8 Plots of discrete distribution functions . . . 1747
18.1.9 Mpmath-inspired functions plots in 2D . . . 1754
18.2 Basic curves . . . 1760
18.2.1 Regular convex polygon . . . 1760
18.2.2 Circle . . . 1761
18.2.3 Ellipse . . . 1762
18.2.4 Parabola . . . 1763
18.2.5 Hyperbola . . . 1764
18.2.6 Cycloid . . . 1765
18.2.7 Trochoid . . . 1766
18.2.8 Cardioid . . . 1767
18.2.9 Limaçon curve . . . 1768
18.2.10 Conchoid of de Sluze . . . 1769
18.2.11 Freeth's Nephroid . . . 1770
18.2.12 Strophoid . . . 1771
18.2.13 Cycloid of Ceva . . . 1772
18.2.14 Lemniscate of Gerono . . . 1773
18.2.15 Lemniscate of Bernoulli . . . 1774
18.3 Spirals . . . 1775

18.3.1 Archimedes' spiral . . . 1775
18.3.2 Fermat's spiral . . . 1776
18.3.3 Hyperbolic Spiral . . . 1777
18.3.4 Lituus . . . 1778
18.3.5 Logarithmic Spiral . . . 1779
18.3.6 Poinsot's Spiral . . . 1780
18.3.7 Cotes's spiral . . . 1781
18.3.8 Tanh Spiral . . . 1782
18.3.9 Nielsens Spiral . . . 1783
18.3.10 Cornu Spiral . . . 1784
18.4 Decorative curves . . . 1785
18.4.1 Fish curve . . . 1785
18.4.2 Heart curve . . . 1786
18.4.3 Chrysanthemum curve . . . 1787
18.4.4 Butterfly curve . . . 1788
18.5 General curve families . . . 1789
18.5.1 Regular star polygon . . . 1789
18.5.2 Regular compound polygon (polygram) . . . 1790
18.5.3 Epicycloid . . . 1791
18.5.4 Hypocycloid . . . 1792
18.5.5 Epitrochoid . . . 1793
18.5.6 Hypotrochoid . . . 1794
18.5.7 Rose curve . . . 1795
18.5.8 Lissajous curves . . . 1796
18.5.9 Superellipses (Lamé curves) . . . 1797
18.5.10 Epispirals . . . 1798
18.5.11 Nodal curves (stereographic projections of the clelia) . . . 1799
18.5.12 Cyclic-harmonic curves . . . 1800
18.5.13 Rational circular cubics . . . 1801
18.6 Field lines . . . 1802
18.6.1 Colored electric field lines: 1 positive vs 1 negative charge . . . 1802
18.6.2 Colored electric field lines: 3 positive vs 1 negative charge(s) . . . 1803
18.6.3 Colored electric field lines: 3 positive vs 1 positive charge(s) . . . 1804
18.6.4 Colored electric field lines: 3 positive and 2 negative vs 1 positive charge(s) . . . 1805
18.7 Contours . . . 1806
18.7.1 Open Contourplot . . . 1806
18.7.2 Filled Contourplot . . . 1807
18.7.3 Electric dipole: field lines and open contours . . . 1808
18.7.4 Electric quadrupole: field lines and open contours . . . 1809
18.7.5 Electric dipoles: field lines and filled contours . . . 1810
18.7.6 Electric quadrupole: field lines and filled contours . . . 1811
18.7.7 Orthogonal electric dipoles: field lines and filled contours . . . 1812
18.7.8 Electric field lines around a point charge with grounded sphere . . . 1813
18.8 Complex functions rendered as contours . . . 1814
18.8.1 Complex square function . . . 1814
18.8.2 Complex sqrt function . . . 1815
18.8.3 Complex exp function . . . 1816
18.8.4 Complex log function . . . 1817
18.8.5 Complex sine function . . . 1818
18.8.6 Complex asin function . . . 1819
18.8.7 Complex tan function . . . 1820
18.8.8 Complex atan function . . . 1821
18.9 Streams, barbs and quivers (some require cartopy) . . . 1822
18.9.1 Streams, Electric Dipole: vector field . . . 1822

18.9.2 Streams, Electric Quadrupole: vector field . . . 1823
18.9.3 Streams, Electric Octopole: vector field . . . 1824
18.9.4 Streams, Electric Hexapole: vector field . . . 1825
18.9.5 Streams, North Atlantic Ocean and Europe (requires cartopy) . . . 1826
18.9.6 Quivers, North Atlantic Ocean and Europe (requires cartopy) . . . 1827
18.9.7 Quivers, plain and regridded (requires cartopy) . . . 1828
18.9.8 Barbs, North Atlantic Ocean and Europe (requires cartopy) . . . 1829

19 Bitmaps **1830**
19.1 Fractals: introduction . . . 1830
19.1.1 Barnsley's Fern . . . 1831
19.1.2 Dragon curve . . . 1832
19.1.3 Sierpiński carpet . . . 1833
19.2 Fractals related to the Mandelbrot set . . . 1834
19.2.1 Mandelbrot set, example 1, classical set: $z_{n+1} = z_n^2 + c$ . . . 1834
19.2.2 Mandelbrot set, example 2: higher powers . . . 1835
19.2.3 Mandelbrot set, example 3: $z_{n+1} = z_n^5 + \frac{c}{z_n}$ . . . 1836
19.2.4 Mandelbrot set, example 4: $z_{n+1} = z_n^5 + \frac{c}{z_n^5}$ . . . 1837
19.2.5 Mandelbrot set, example 5, "Inverse Mandelbrot" . . . 1838
19.2.6 Mandelbrot set, example 6, "Marek Dragon Fractal": . . . 1839
19.2.7 Mandelbrot set, example 7, "Burning Ship Fractal" . . . 1840
19.3 Fractals related to the Julia set . . . 1841
19.3.1 Julia sets, example 1: Classical set . . . 1841
19.3.2 Julia sets, example 2: Glynn fractals . . . 1842
19.3.3 Julia sets, example 3: Spiral Septagon fractal . . . 1843
19.3.4 Julia sets, example 4: Reuleaux Triangle fractal . . . 1844
19.3.5 Julia sets, example 5: Phoenix Julia fractals . . . 1845
19.3.6 Julia sets, example 6: Cubic Julia fractals . . . 1846
19.3.7 Julia sets, example 7: Spiral Julia fractal (uses $z_{n+1} = \tan(z_n^2 + c)$) . . . 1847
19.3.8 Julia sets, example 8: Julia set of $\sin(z)$ . . . 1848
19.3.9 Julia sets, example 9: Julia09 fractals . . . 1849
19.3.10 Julia sets, example 10: Julia10 fractals . . . 1850
19.3.11 Julia sets, example 11: Julia11 fractals . . . 1851
19.4 Newton Fractals . . . 1852
19.4.1 Newton, zeros of $z^3 - 1$ . . . 1852
19.4.2 Newton, zeros of $\cos(z)$ . . . 1853
19.4.3 Modified Newton (containing an error), zeros of $z^3 - 1$ . . . 1854
19.4.4 Modified Newton (containing an error), not converging . . . 1855
19.4.5 Halley, zeros of $z^3 - 1$ . . . 1856
19.4.6 Halley, zeros of $\cos(z)$ . . . 1857
19.4.7 Modified Halley (containing an error), zeros of $z^3 - 1$ . . . 1858
19.5 Domain coloring . . . 1859
19.5.1 Domain coloring without contours: $f(z) = (z^3 - 1)/z$ . . . 1860
19.5.2 Domain coloring with contours of the phase: $f(z) = (z^3 - 1)/z$ . . . 1861
19.5.3 Domain coloring with contours of the modulus: $f(z) = (z^3 - 1)/z$ . . . 1862
19.5.4 Domain coloring with contours of phase and modulus: $f(z) = (z^3 - 1)/z$ . . . 1863
19.5.5 Domain coloring with contours of phase and modulus: $f(z) = z^5 + z$ . . . 1864
19.5.6 Domain coloring with contours of phase and modulus: $f(z) = (z^6 - 1)/(z^{12} + 1)$ . . . 1865
19.5.7 Domain coloring with contours of phase and modulus: $f(z) = (z - 0.5(1 + i))/z^2$ . . . 1866
19.5.8 Domain coloring with contours of phase and modulus: $f(z) = \exp(1/z)$ . . . 1867
19.5.9 Domain coloring with contours of phase and modulus: $f(z) = z\exp(1/z)$ . . . 1868
19.5.10 Domain coloring with contours of phase and modulus: $f(z) = \exp(1/z^2)$ . . . 1869
19.5.11 Domain coloring with contours of phase and modulus: $f(z) = \sin(z)$ . . . 1870
19.5.12 Domain coloring with contours of phase and modulus: $f(z) = z\sin(1/z)$ . . . 1871

19.5.13 Domain coloring with contours of phase and modulus: $f(z) = \sin(z)/(z-i)^2$ . . . 1872
19.5.14 Domain coloring with contours of phase and modulus: $f(z) = \tan(z)$ . . . 1873

20 Matplotlib 3D Graphics **1874**
20.1 Introduction . . . 1874
20.1.1 Overview . . . 1874
20.2 Matplotlib: 3D Graphics (from Matplotlib tutorials) . . . 1875
20.2.1 Klein bottle . . . 1875
20.2.2 Lorentz attractor . . . 1876
20.2.3 Parametric curve . . . 1877
20.2.4 Projected filled contour . . . 1878
20.2.5 Projected open contour . . . 1879
20.2.6 Scatterplot . . . 1880
20.2.7 Surface colormap . . . 1881
20.2.8 Surface hillshading . . . 1882
20.2.9 Surface solid . . . 1883
20.2.10 Surface triangular . . . 1884
20.3 S3dlib: Basic geometric figures . . . 1885
20.3.1 Base 3D class surface . . . 1885
20.3.2 Hypercube . . . 1886
20.3.3 Surface elements . . . 1887
20.3.4 Hyperboloid 3D . . . 1888
20.3.5 Conic sections . . . 1889
20.3.6 Base 3D class surface, part 2 . . . 1890
20.3.7 Rhombicuboctahedron . . . 1891
20.3.8 Rhombicuboctahedron, bubbles . . . 1892
20.4 S3dlib: Real functions . . . 1893
20.4.1 Surface plot of a real function, basic example . . . 1893
20.4.2 Surface plot of a real function, grid . . . 1894
20.4.3 Surface plot of a real function, peaks example . . . 1895
20.4.4 Function plots: Ackley, Himmelblau, Rosenbrock, Rastrigin . . . 1896
20.4.5 McCormick function . . . 1897
20.4.6 Surface plot combined with contour . . . 1898
20.4.7 Sliced polar surface . . . 1899
20.5 S3dlib: Parametric Surfaces . . . 1900
20.5.1 Color representation vs geometric representation, part 1 . . . 1900
20.5.2 Color representation vs geometric representation, part 2 . . . 1901
20.5.3 Color maps: Möbius function example . . . 1902
20.5.4 Shading: Möbius function example . . . 1903
20.5.5 Color maps: Boy, Dini, Bour, Roman, Klein, and Figure8 examples . . . 1904
20.5.6 Colored knot in 3D . . . 1905
20.5.7 Multiple geometric maps . . . 1906
20.5.8 Example from Mayavi . . . 1907
20.5.9 S3Dlib Logo . . . 1908
20.5.10 Spherical harmonics, 3D representation . . . 1909
20.5.11 Boy surface . . . 1910
20.5.12 Dini surface . . . 1911
20.5.13 Bour surface . . . 1912
20.5.14 Roman surface . . . 1913
20.5.15 Klein bottle . . . 1914
20.5.16 Klein bottle8 . . . 1915
20.6 S3dlib: Image mapping and clipping . . . 1916
20.6.1 Image HSV value clipping . . . 1916
20.6.2 Spherical image mapping . . . 1917

20.6.3 Earth in 3D . . . 1918
20.6.4 Cylindrical image mapping . . . 1919
20.6.5 Imaginary Earth, part A . . . 1920
20.6.6 Imaginary Earth, part B . . . 1921
20.6.7 Earth, projected on Klein bottle . . . 1922
20.6.8 Earth, projected on planar, screw, knot and swirl surfaces . . . 1923
20.7 S3dlib: Edge-to-edge surface coloring . . . 1924
20.7.1 Platonic solid, with surface edges filled, part 1 . . . 1924
20.7.2 Platonic solid, with surface edges filled, part 2 . . . 1925
20.7.3 Spherical contour surface, filled . . . 1926
20.7.4 Edge-to-edge surface, part 1 . . . 1927
20.7.5 Spherical edge surface, filled . . . 1928
20.7.6 Edge-to-edge surface, part 2 . . . 1929
20.7.7 Line colormap sequence . . . 1930
20.7.8 Sequential line color, part 1 . . . 1931
20.7.9 Sequential line color, part 2 . . . 1932
20.8 S3dlib: Decorative parametric surfaces . . . 1933
20.8.1 Shell surface with colormap . . . 1933
20.8.2 Escher Knot . . . 1934
20.8.3 Escher sphere spirals . . . 1935
20.8.4 Escher spirals . . . 1936
20.9 S3dlib: Geometric and color datagrid mapping (requires scipy) . . . 1937
20.9.1 Mandelbrot contours . . . 1937
20.9.2 Geometric and color datagrid mapping . . . 1938
20.9.3 MRI 3D . . . 1939
20.9.4 Jacksboro fault . . . 1940
20.9.5 Mandelbrot 3D . . . 1941
20.9.6 MRI regions . . . 1942
20.10 S3dlib: Implicit surfaces (requires scikit-image) . . . 1943
20.10.1 Sphere (implicit definition), part 1 . . . 1943
20.10.2 Sphere (implicit definition), part 2 . . . 1944
20.10.3 Goursat surface . . . 1945
20.10.4 Schwarz P surface . . . 1946
20.10.5 Nodal surface . . . 1947
20.10.6 Spirals surface . . . 1948
20.10.7 Iso surface . . . 1949
20.10.8 Implicit surface . . . 1950

21 Plotly **1951**
21.1 General surface plots in 3D . . . 1951
21.1.1 Mount Bruno . . . 1951
21.1.2 Ring Cyclide . . . 1952
21.1.3 Torus . . . 1953
21.1.4 Möbius surface . . . 1954
21.1.5 Boy surface . . . 1955
21.1.6 Overlaid function . . . 1956
21.1.7 Iris data . . . 1957
21.2 Geographical plots . . . 1958
21.2.1 Movable projection of the world . . . 1958
21.2.2 Rotatable globe . . . 1959
21.2.3 Choropleth of the US with Alaska and Hawai . . . 1960
21.2.4 Voting results embedded in map . . . 1961
21.3 Sankey plots . . . 1962
21.3.1 Sankey plot 1 . . . 1962

21.3.2 Sankey plot 2 . . . 1963
21.3.3 Sankey plot 3 . . . 1964

V Interactive 3D Wpf Plots 1965

22 Wpf: Altitude surfaces in 3D, real and complex functions 1966
22.1 Special techniques for height surfaces, real and complex functions . . . 1966
22.1.1 Wpf figures as standard display of complex functions . . . 1966
22.1.2 Truncation vs loglog transformation . . . 1967
22.1.3 Displaying branch cuts . . . 1967
22.2 Scatterplots and building 3D scenes . . . 1968
22.2.1 Scatter plot of bivariate normal . . . 1968
22.2.2 Scatter plot of surfaces . . . 1969
22.3 Height plots of general bivariate real functions . . . 1970
22.3.1 Hyperbolic paraboloid . . . 1970
22.3.2 Array Surface, general . . . 1971
22.3.3 Fractal Landscape surface . . . 1972
22.3.4 Sombrero function . . . 1973
22.3.5 General 3D Wave function . . . 1974
22.3.6 Bivariate normal function . . . 1974

23 Wpf: Parametric surfaces 1975
23.1 Surfaces of translation . . . 1975
23.1.1 Fermat spiral as generator . . . 1975
23.1.2 Lemniscate as generator . . . 1976
23.1.3 Tanh spiral as generator . . . 1977
23.1.4 Rose curve as generator . . . 1978
23.1.5 Hypocycloid as generator . . . 1979
23.1.6 Epicycloid as generator . . . 1980
23.2 Surfaces of revolution . . . 1981
23.2.1 One-Sheeted Hyperboloid . . . 1981
23.2.2 Sphere . . . 1982
23.2.3 Prolate Spheroid . . . 1983
23.2.4 Oblate Spheroid . . . 1984
23.2.5 Drop surface . . . 1985
23.2.6 Egg surface . . . 1986
23.2.7 Apple surface . . . 1987
23.2.8 Spinning top . . . 1988
23.2.9 Pseudosphere . . . 1989
23.2.10 Wave sphere Surface . . . 1990
23.2.11 Torus . . . 1991
23.2.12 Horn Torus . . . 1992
23.2.13 Spindle Torus . . . 1993
23.2.14 Elliptic Torus . . . 1994
23.3 Generalisations of common surfaces . . . 1995
23.3.1 Ellipsoid . . . 1995
23.3.2 Superellipsoid . . . 1996
23.3.3 Hexaedron . . . 1997
23.3.4 Super Toroid . . . 1998
23.3.5 Elliptic Helicoid . . . 1999
23.3.6 Hyperbolic Helicoid . . . 2000
23.3.7 Lemniscate . . . 2001
23.3.8 Bohemian Dome . . . 2002

23.3.9 Dupin1 surface . . . 2003
23.3.10 Dupin2 surface . . . 2004
23.3.11 Dinis Surface (twisted pseudosphere) . . . 2005
23.3.12 Plueckers conoid . . . 2006
23.3.13 Umbilic Torus . . . 2007
23.3.14 Skidian's ruled surface . . . 2008
23.3.15 Umbrella surface . . . 2009
23.3.16 Cyclic surfaces (generalized torus) . . . 2010
23.3.17 Goursat surfaces . . . 2012
23.3.18 Cyclides triples . . . 2014
23.3.19 Ship Lamé . . . 2016
23.4 Minimal surfaces . . . 2017
23.4.1 Catenoid . . . 2017
23.4.2 Helicoid . . . 2018
23.4.3 Bours minimal surface . . . 2019
23.4.4 Catalan minimal surface . . . 2020
23.4.5 Ennepers first minimal surface . . . 2021
23.4.6 Enneper second minimal surface . . . 2022
23.4.7 Hennebergs minimal surface . . . 2023
23.4.8 Scherk's first minimal surface . . . 2024
23.4.9 Scherk's second minimal surface . . . 2025
23.4.10 Richmond minimal surface . . . 2026
23.4.11 Generalized Ennneper surfaces . . . 2027
23.5 Nonorientable (one-sided) Surfaces . . . 2028
23.5.1 Moebius Strip . . . 2028
23.5.2 Cross-Cap Surface . . . 2029
23.5.3 Pseudo Cross-Cap Surface . . . 2030
23.5.4 Roman Surface (or Steiner Surface) . . . 2031
23.5.5 Klein bagel . . . 2032
23.5.6 Klein bottle . . . 2033
23.5.7 3D Boy Surface, version 1 . . . 2034
23.5.8 3D Boy Surface, version 2 . . . 2035
23.5.9 Morin Surface . . . 2036
23.6 Decorative parametric surfaces . . . 2037
23.6.1 Bourke Seashell . . . 2037
23.6.2 Seashell (mathworld.wolfram) . . . 2038
23.6.3 3D Apple . . . 2039
23.6.4 Bow curve . . . 2040
23.6.5 Fish Surface . . . 2041
23.6.6 Bourke Horn . . . 2042
23.6.7 Hexa torus . . . 2043
23.6.8 3D Breather Surface . . . 2044
23.6.9 Kuen surface . . . 2045
23.6.10 Tranguloid trefoil . . . 2046
23.6.11 Triaxial teardrop . . . 2047
23.6.12 Gray Bottle . . . 2048
23.6.13 Surfaces mimicking snail shells . . . 2049

24 Wpf: Path surfaces in 3D **2052**
24.1 Introduction to path surfaces . . . 2052
24.1.1 Borromean rings, A, B, C . . . 2052
24.1.2 Ellipses, A, B, C . . . 2054
24.1.3 Trefoil 2 . . . 2055
24.1.4 Formatting options for path surfaces, Trefoil 5 . . . 2056

24.2 Functions with real input and complex results . . . 2057
24.2.1 Expj (Cis) function . . . 2057
24.2.2 Hankel function of the first kind $H_{1,\nu}(x)$ . . . 2059
24.2.3 Hankel function of the second kind $H_{2,\nu}(x)$ . . . 2060
24.2.4 Kelvin functions ber and bei . . . 2061

26 Real elementary functions 2151
26.1 Root, exponential, logarithmic and power functions . . . 2152
26.1.1 Auxiliary function $\mathrm{sqrt1pmx}(x) = \sqrt{1+x^2} - x$ . . . 2152
26.1.2 Bring radical . . . 2152
26.1.3 Auxiliary function $\mathrm{expmx2h}(x) = \exp(-x^2/2)$ . . . 2152
26.1.4 Relative error exponential $\mathrm{exprel}(x) = (\exp(x) - 1)/x$ . . . 2152

26.1.5 Auxiliary function $\mathrm{expx2}(x) = \exp(x \cdot |x|)$ . . . 2153
26.1.6 Auxiliary function $\mathrm{logistic}(x) = 1/(1 + \exp(-x))$ . . . 2153
26.1.7 Einstein functions . . . 2154
26.1.8 Auxiliary function $\mathrm{log1mexp}(x) = \log(1 - \exp(-|x|))$ . . . 2154
26.1.9 Auxiliary function $\mathrm{log1pexp}(x) = \log(1 + \exp(x))$ . . . 2155
26.1.10 Auxiliary function $\mathrm{log1pmx}(x) = \log(1 + x) - x$ . . . 2155
26.1.11 Auxiliary function $\mathrm{logaddexp}(x, y) = \log[\exp(x) + \exp(y)]$ . . . 2155
26.1.12 Auxiliary function $\mathrm{logsubexp}(x, y) = \log[\exp(x) - \exp(y)]$ . . . 2156
26.1.13 Auxiliary function $\mathrm{logit}(x) = \log(x/(1.0 - x))$ . . . 2156
26.1.14 Wright ω function . . . 2156
26.1.15 Auxiliary function $\mathrm{compound}(x, n) = (1 + x)^n$ . . . 2156
26.1.16 Auxiliary function $\mathrm{comprel}(x, n) = (1 + x)^n - 1$ . . . 2157
26.1.17 Auxiliary function $\mathrm{hypot3}(x, y, z) = \sqrt{x^2 + y^2 + z^2}$ . . . 2157
26.1.18 Fibonacci polynomials, $\mathrm{fibpoly}(n, x)$ . . . 2157
26.1.19 Lucas polynomials, $\mathrm{lucaspoly}(n, x)$ . . . 2158
26.1.20 Fibonacci function, $F_\nu(x)$, of real index ν . . . 2158
26.2 Trigonometric functions . . . 2159
26.2.1 Sine, x in degrees, $\mathrm{sind}(x)$ . . . 2159
26.2.2 Inverse sine, input in degrees, $\mathrm{asind}(x)$ . . . 2159
26.2.3 Cosine, x in degrees, $\mathrm{cosd}(x)$ . . . 2159
26.2.4 Inverse cosine, input in degrees, $\mathrm{acosd}(x)$ . . . 2159
26.2.5 Tangent, with x in degrees, $\mathrm{tand}(x)$ . . . 2159
26.2.6 Inverse tangent, input in degrees, $\mathrm{atand}(x)$ . . . 2160
26.2.7 Cotangent, with x in degrees, $\mathrm{cotd}(x)$ . . . 2160
26.2.8 Inverse cotangent, input in degrees, $\mathrm{acotd}(x)$ . . . 2160
26.2.9 Auxiliary function, $\mathrm{acos}(1 - x)$ . . . 2160
26.2.10 Haversine function $\mathrm{hav}(x) = (1 - \cos(x))/2$ . . . 2160
26.2.11 Inverse haversine function $\mathrm{archav}(x) = \mathrm{acos}(1 - 2x)$ . . . 2160
26.2.12 Versine function $\mathrm{vers}(x) = 1 - \cos(x)$ . . . 2161
26.2.13 Coversine, $\mathrm{covers}(x) = 1 - \sin(x)$ . . . 2161
26.2.14 Versint function $\mathrm{versint}(x) = x - \sin(x)$ . . . 2161
26.2.15 Integral of cos powers, $\mathrm{cosint}(n, x)$ . . . 2161
26.2.16 Integral of sin powers, $\mathrm{sinint}(n, x)$ . . . 2162
26.3 Hyperbolic functions . . . 2163
26.3.1 Cardinal hyperbolic sine, $\mathrm{sinhc}(x) = \sinh(x)/x$ . . . 2163
26.3.2 Auxiliary function, $\mathrm{sinhmx}(x) = \sinh(x) - x$ . . . 2163
26.3.3 Auxiliary function, $\mathrm{coshm1}(x) = \cosh(x) - 1$ . . . 2163
26.3.4 Auxiliary function $\mathrm{acosh}(1 + x)$ . . . 2163
26.3.5 Auxiliary function $\log(\cosh(x))$ . . . 2164
26.3.6 Auxiliary function $\log(\sinh(x))$ . . . 2164
26.3.7 Gudermannian function $\mathrm{gd}(x) = \mathrm{asin}(\tanh(x))$ . . . 2164
26.3.8 Inverse Gudermannian function $\mathrm{arcgd}(x) = \mathrm{atanh}(\sin(x))$ . . . 2164
26.3.9 Langevin function, $L(x)$ . . . 2164
26.3.10 Inverse Langevin function, $L^{-1}(x)$ . . . 2165
26.3.11 Solutions of Kepler's equation, $\mathrm{kepler}(M, e)$ . . . 2165
26.4 Gamma functions . . . 2166
26.4.1 Sign of the gamma function . . . 2166
26.4.2 Logarithm and sign of the gamma function . . . 2166
26.4.3 Logarithm of $\Gamma(1 + x)$ . . . 2166
26.4.4 Logarithm of factorials: $\log(x!)$ . . . 2166
26.4.5 Logarithm of the binomial coefficient . . . 2167
26.4.6 Log-Beta function . . . 2167
26.4.7 Inverse of the gamma function, $\Gamma^{-1}(y)$ . . . 2167
26.4.8 Inverse of the logarithm of the gamma function, $\log \Gamma^{-1}(y)$ . . . 2167

26.4.9 Temme's regulated gamma function, $\Gamma^*(x)$ . . . 2168
26.4.10 Relative Pochhammer symbol, $((a)_x - 1)/x$ . . . 2168
26.4.11 Catalan function $C(x)$ . . . 2168

27 Real elliptic functions **2170**
27.1 Conversions of parameters of elliptic functions . . . 2171
27.1.1 Elliptic nome $q(k)$ (DAMath) . . . 2171
27.1.2 Elliptic modulus $k(q)$ (DAMath) . . . 2171
27.1.3 Jacobi amplitude, $\mathrm{am}(x, k)$ (DAMath) . . . 2171
27.2 Elliptic integrals . . . 2172
27.2.1 Legendre complete elliptic integral $B(k)$ . . . 2172
27.2.2 Legendre complete elliptic integral $D(k)$ . . . 2172
27.2.3 Legendre incomplete elliptic integral $B(\phi, k)$ . . . 2172
27.2.4 Legendre incomplete elliptic integral $D(\phi, k)$ . . . 2172
27.2.5 Heuman's Lambda function, $\Lambda_0(\phi, k)$ . . . 2173
27.2.6 Jacobi Zeta function, $Z(\phi, k)$ . . . 2173
27.3 Bulirsch elliptic integrals . . . 2175
27.3.1 Complete elliptic integral of the 1st kind $\mathrm{cel1}(k_c)$ . . . 2175
27.3.2 Complete elliptic integral of the 2nd kind $\mathrm{cel2}(k_c, a, b)$ . . . 2175
27.3.3 General complete elliptic integral $\mathrm{cel}(k_c, p, a, b)$ . . . 2176
27.3.4 Incomplete elliptic integral of the 1st kind $\mathrm{el1}(x, k_c)$ . . . 2176
27.3.5 Incomplete elliptic integral of the 2nd kind $\mathrm{el2}(x, k_c, a, b)$ . . . 2176
27.3.6 Incomplete elliptic integral of the 3rd kind $\mathrm{el3}(x, k_c, p)$ . . . 2176
27.4 Maple style elliptic integrals . . . 2178
27.4.1 Complete integral of the 1st kind, $\mathrm{EllipticK}(k)$ . . . 2178
27.4.2 Complete integral of the 1st kind for imaginary modulus, $\mathrm{EllipticKim}(k)$ . . . 2178
27.4.3 Complementary complete integral of the 1st kind, $\mathrm{EllipticCK}(k) = K'(k)$ . . . 2178
27.4.4 Complete integral of the 2nd kind, $\mathrm{EllipticEC}(k)$ . . . 2179
27.4.5 Complete integral of the 2nd kind for imaginary modulus, $\mathrm{EllipticECim}(k)$ . . . 2179
27.4.6 Complementary complete integral of the 2nd kind, $\mathrm{EllipticCE}(k)$ . . . 2179
27.4.7 Complete integral of the 3rd kind, $\mathrm{EllipticPiC}(\nu, k)$ . . . 2179
27.4.8 Complete integral of the 3rd kind for imaginary modulus, $\mathrm{EllipticPiCim}(\nu, k)$ . . . 2180
27.4.9 Complementary complete integral of the 3rd kind, $\mathrm{EllipticCPi}(\nu, k)$ . . . 2180
27.4.10 Incomplete integral of the 1st kind, $\mathrm{EllipticF}(z, k)$ . . . 2180
27.4.11 Incomplete integral of the 2nd kind, $\mathrm{EllipticE}(z, k)$ . . . 2181
27.4.12 Incomplete integral of the 3rd kind, $\mathrm{EllipticPi}(z, \nu, k)$ . . . 2181
27.5 Jacobi theta functions at $x = 0$ for $0 \le q < 1$ . . . 2182
27.5.1 Jacobi theta function $\theta_1'(q)$ . . . 2182
27.5.2 Jacobi theta function $\theta_2(q)$ . . . 2182
27.5.3 Jacobi theta function $\theta_3(q)$ . . . 2182
27.5.4 Jacobi theta function $\theta_4(q)$ . . . 2182
27.6 Inverse Jacobi elliptic functions . . . 2183
27.6.1 Inverse Jacobi elliptic function $\mathrm{arcsn}(x, k)$ . . . 2183
27.6.2 Inverse Jacobi elliptic function $\mathrm{arccn}(x, k)$ . . . 2183
27.6.3 Inverse Jacobi elliptic function $\mathrm{arcdn}(x, k)$ . . . 2183
27.6.4 Inverse Jacobi elliptic function $\mathrm{arccd}(x, k)$ . . . 2184
27.6.5 Inverse Jacobi elliptic function $\mathrm{arcsd}(x, k)$ . . . 2184
27.6.6 Inverse Jacobi elliptic function $\mathrm{arcnd}(x, k)$ . . . 2184
27.6.7 Inverse Jacobi elliptic function $\mathrm{arcdc}(x, k)$ . . . 2184
27.6.8 Inverse Jacobi elliptic function $\mathrm{arcnc}(x, k)$ . . . 2185
27.6.9 Inverse Jacobi elliptic function $\mathrm{arcsc}(x, k)$ . . . 2185
27.6.10 Inverse Jacobi elliptic function $\mathrm{arcns}(x, k)$ . . . 2185
27.6.11 Inverse Jacobi elliptic function $\mathrm{arcds}(x, k)$ . . . 2186
27.6.12 Inverse Jacobi elliptic function $\mathrm{arccs}(x, k)$ . . . 2186

27.7 Lemniscate functions . . . 2187
27.7.1 Lemniscate sine function, $\mathrm{sinlemn}(x)$ . . . 2187
27.7.2 Lemniscate cosine function, $\mathrm{coslemn}(x)$ . . . 2187
27.7.3 Inverse lemniscate sine function, $\mathrm{arcsl}(x)$ . . . 2187
27.7.4 Inverse lemniscate cosine function, $\mathrm{arccl}(x)$ . . . 2187

28 Real functions related to Lerchs phi **2189**
28.1 Polygamma, and related functions . . . 2190
28.1.1 Pentagamma function $\psi'''(x)$ . . . 2190
28.1.2 Tetragamma function, $\psi''(x)$ . . . 2190
28.1.3 Auxiliary function $\psi^*(x)$ . . . 2190
28.1.4 Inverse digamma function $\psi^{-1}(y)$ . . . 2190
28.1.5 Bateman function $G(x)$ . . . 2191
28.2 Polylogarithm, and related functions . . . 2192
28.2.1 Polylogarithm of integer order, $\mathrm{Li}_n(x)$ . . . 2192
28.2.2 Fermi-Dirac integrals of integer order, $F_n(x)$ . . . 2192
28.2.3 Fermi-Dirac integral $F_{-1/2}(x)$ . . . 2192
28.2.4 Fermi-Dirac integral $F_{1/2}(x)$ . . . 2193
28.2.5 Fermi-Dirac integral $F_{3/2}(x)$ . . . 2193
28.2.6 Fermi-Dirac integral $F_{5/2}(x)$ . . . 2193
28.2.7 Inverse tangent integral, $\mathrm{Ti}_2(x)$ . . . 2193
28.2.8 Lobachevsky's log-cos integral, $L(x)$ . . . 2194
28.2.9 Lobachevsky's log-sin integral, $\Lambda(x)$ . . . 2194
28.2.10 Debye functions, $\mathrm{D}_n(x)$ . . . 2194
28.2.11 Transport integral, $\mathrm{J}_n(x)$ . . . 2195
28.3 Riemann zeta, and related functions . . . 2196
28.3.1 Riemann $\zeta(n)$ for integer arguments . . . 2196
28.3.2 Riemann $\zeta(1+x)$ . . . 2196
28.3.3 Dirichlet eta function for integer argument, $\eta(n)$ . . . 2196
28.3.4 Prime zeta function . . . 2196
28.3.5 Riemann prime counting function, $R(x)$ . . . 2197
28.3.6 Inverse of the Riemann prime counting function, $R^{-1}(x)$ . . . 2197
28.3.7 Rogers-Ramanujan continued fraction . . . 2197
28.3.8 Moebius function, $\mu(n)$ . . . 2198
28.3.9 q-Pochhammer Euler function, $(q)_\infty$ . . . 2198
28.4 Miscellaneous functions . . . 2199
28.4.1 Log-series distribution, pmf . . . 2199
28.4.2 Log-series distribution, cdf . . . 2199
28.4.3 Zeta distribution, pmf . . . 2199
28.4.4 Zeta distribution, cdf . . . 2200

29 Real functions related to ${}_0F_1$ **2201**
29.1 Bessel functions of integer order . . . 2201
29.1.1 Bessel function of the 1st kind, order 0, $J_0(x)$ . . . 2201
29.1.2 Bessel function of the 1st kind, order 1, $J_1(x)$ . . . 2201
29.1.3 Bessel function of the 1st kind, integer order n, $J_n(x)$ . . . 2201
29.1.4 Bessel function of the 2nd kind, order 0, $Y_0(x)$ . . . 2202
29.1.5 Bessel function of the 2nd kind, order 1, $Y_1(x)$ . . . 2202
29.1.6 Bessel function of the 2nd kind, integer order n, $Y_n(x)$ . . . 2202
29.1.7 Bessel Lambda function, $\Lambda(\nu, x)$ . . . 2204
29.2 Modified Bessel functions of integer order . . . 2205
29.2.1 Modified Bessel function of the 1st kind, order 0, $I_0(x)$ . . . 2205
29.2.2 Modified Bessel function of the 1st kind, order 1, $I_1(x)$ . . . 2205
29.2.3 Modified Bessel function of the 1st kind, integer order n, $I_n(x)$ . . . 2205

29.2.4 Modified Bessel function of the 2nd kind, order 0, $K_0(x)$ . . . 2205
29.2.5 Modified Bessel function of the 2nd kind, order 1, $K_1(x)$ . . . 2206
29.2.6 Modified Bessel function of the 2nd kind, integer order n, $K_n(x)$ . . . 2206
29.2.7 Exponentially scaled modified Bessel function of the 1st kind, order 0, $I_{0,e}(x)$ . . . 2206
29.2.8 Exponentially scaled modified Bessel function of the 1st kind, order 1, $I_{1,e}(x)$ . . . 2207
29.2.9 Exponentially scaled modified Bessel function of the 2nd kind, order 0, $K_{0,e}(x)$ . . . 2207
29.2.10 Exponentially scaled modified Bessel function of the 2nd kind, order 1, $K_{1,e}(x)$ . . . 2207
29.3 Integrals of zero-order Bessel functions . . . 2208
29.3.1 Integral of I_0 . . . 2208
29.3.2 Integral of J_0 . . . 2208
29.3.3 Integral of K_0 . . . 2208
29.3.4 Integral of Y_0 . . . 2208
29.4 Kelvin functions of order 0 . . . 2210
29.4.1 Kelvin function $\mathrm{ber0}(x)$ . . . 2210
29.4.2 Kelvin function $\mathrm{bei0}(x)$ . . . 2210
29.4.3 Kelvin function $\mathrm{ker0}(x)$ . . . 2210
29.4.4 Kelvin function $\mathrm{kei0}(x)$ . . . 2211
29.4.5 First derivative of the Kelvin function $\mathrm{ber0}, \mathrm{ber0}'(x)$ . . . 2211
29.4.6 First derivative of the Kelvin function $\mathrm{bei0}, \mathrm{bei0}'(x)$ . . . 2211
29.4.7 First derivative of the Kelvin function $\mathrm{ker0}, \mathrm{ker0}'(\nu, x)$ . . . 2212
29.4.8 First derivative of the Kelvin function $\mathrm{kei0}, \mathrm{kei0}'(x)$ . . . 2212
29.5 Synchrotron functions . . . 2213
29.5.1 First synchrotron function $F(x)$ . . . 2213
29.5.2 Second synchrotron function $G(x)$ . . . 2213

30 Real functions related to ${}_1F_1$ 2214
30.1 Incomplete gamma functions . . . 2215
30.1.1 Truncated exponential function, $e_n(x)$ . . . 2215
30.1.2 Relative exponential, $\mathrm{exprel}_n(x)$ . . . 2215
30.2 Coulomb wave functions . . . 2216
30.2.1 Normalizing Gamow constant for Coulomb wave functions . . . 2216
30.2.2 Coulomb phase shift $\sigma_L(\eta)$ . . . 2217
30.2.3 Regular Coulomb wave functions $F_l(\eta, x), F_l'(\eta, x)$ . . . 2218
30.2.4 Irregular Coulomb wave functions $G_l(\eta, z), x), G_l'(\eta, z)$ . . . 2219
30.3 Error function, and related functions . . . 2220
30.3.1 Exponentially scaled complementary error function, $\mathrm{erfcx}(x)$ . . . 2220
30.3.2 Difference of error functions, $\mathrm{erfh}(x, h) = \mathrm{erf}(x + h) - \mathrm{erf}(x - h)$ . . . 2220
30.3.3 Difference of error functions, $\mathrm{erf2}(x_1, x_2) = \mathrm{erf}(x_2) - \mathrm{erf}(x_1)$ . . . 2220
30.3.4 Probability function $Q(x) = \Phi(-x)$ . . . 2220
30.3.5 Inverse of the exponentially scaled complementary error function, $\mathrm{erfcx}^{-1}(x)$ . . . 2221
30.3.6 Inverse of the imaginary error function, $\mathrm{erfi}^{-1}(x)$ . . . 2221
30.3.7 Generalized Dawson integral, $F(p, x)$ . . . 2221
30.3.8 Generalized error function, $\mathrm{erfg}(p, x)$ . . . 2221
30.3.9 Expint3, $\mathrm{erfg}(3, x)$ . . . 2222
30.3.10 Scaled repeated integrals of the complementary error function, $i^n\mathrm{erfc}(x)$ . . . 2222
30.3.11 Fresnel auxiliary function $\mathrm{f}(x)$ . . . 2223
30.3.12 Fresnel auxiliary function $\mathrm{g}(x)$ . . . 2223
30.3.13 Goodwin-Staton integral, $G(x)$ . . . 2223
30.3.14 Voigt function U . . . 2224
30.3.15 Voigt function V . . . 2224
30.3.16 Voigt function H . . . 2224
30.3.17 Voigt Profile distribution, pdf . . . 2225
30.4 Exponential integrals, and related functions . . . 2226
30.4.1 Entire cosine integral $\mathrm{Cin}(x)$ . . . 2226

30.4.2 Entire hyperbolic cosine integral $\mathrm{Cinh}(x)$ . . . 2226
30.4.3 Entire exponential integral $\mathrm{Ein}(x)$ . . . 2226
30.4.4 Scaled exponential integral $\mathrm{e1s}(x)$ . . . 2226
30.4.5 Scaled exponential integral $\mathrm{eis}(x)$ . . . 2227
30.4.6 Scaled exponential integral $\mathrm{eisx2}(x)$ . . . 2227
30.4.7 Inverse of the exponential integral, $\mathrm{Ei}^{-1}(x)$ . . . 2227
30.4.8 Generalized exponential integral $E_p(p, x)$ . . . 2227
30.4.9 Exponential integral $\beta_n(x)$ . . . 2228
30.4.10 Inverse of the logarithmic integral, $\mathrm{li}^{-1}(x)$ . . . 2228
30.4.11 Shifted sine integral $\mathrm{si}(x) = \mathrm{Si}(x) - \pi/2$ . . . 2228
30.5 Struve functions . . . 2229
30.5.1 Struve function $\mathbf{H}_0(x)$ . . . 2229
30.5.2 Struve function $\mathbf{H}_1(x)$ . . . 2229
30.5.3 Struve function $\mathbf{L}_0(x)$ . . . 2229
30.5.4 Struve function $\mathbf{L}_1(x)$ . . . 2229

31 Real and complex functions **2231**
31.1 Additional elementary complex functions . . . 2232
31.1.1 Auxiliary function $\sqrt{1 - z^2}$ . . . 2232
31.1.2 Cube root, $\mathrm{cuberoot}(x) = \sqrt[3]{x} = y$, with $\arg(y)$ closest to $\arg(x)$ . . . 2232
31.1.3 Nth root, $\mathrm{surd}(x, n) = \sqrt[n]{x} = y$, with $\arg(y)$ closest to $\arg(x)$ . . . 2232
31.1.4 Continuous inverse cotangent, $\mathrm{acotc}(x)$ . . . 2232
31.1.5 Continuous inverse hyperbolic cotangent, $\mathrm{acothc}(x)$ . . . 2233
31.2 Neville theta functions . . . 2234
31.2.1 Neville $\theta_s(x, k)$ . . . 2234
31.2.2 Neville $\theta_c(x, k)$ . . . 2234
31.2.3 Neville $\theta_d(x, k)$ . . . 2234
31.2.4 Neville $\theta_n(x, k)$ . . . 2234
31.3 Conversions of parameters of Weierstrass $\wp$ . . . 2236
31.3.1 Elliptic lattice roots e_1, e_2, e_3 from elliptic lattice invariants g_2, g_3 . . . 2236
31.3.2 Elliptic half periods ω_1, ω_2 from elliptic lattice invariants g_2, g_3 . . . 2238
31.3.3 Elliptic half-period ω_1 and elliptic period ratio τ from elliptic lattice invariants g_2 and g_3 . . . 2240
31.4 Weierstrass elliptic functions, in terms of (real) lattice invariants g_2, g_3 . . . 2242
31.4.1 Weierstrass function $\wp_g(z, g_2, g_3)$ (also DAMath) . . . 2242
31.4.2 Weierstrass function, first derivative: $\wp'_g(z, g_2, g_3)$ . . . 2244
31.4.3 Inverse Weierstrass function $\wp_g^{-1}(z, g_2, g_3)$ . . . 2246
31.4.4 Weierstrass Zeta function $\zeta_g(z, g_2, g_3)$ . . . 2247
31.4.5 Weierstrass Sigma function $\sigma_g(z, g_2, g_3)$ . . . 2248
31.5 Weierstrass elliptic functions, in terms of (real) lattice roots e_1, e_2 . . . 2249
31.5.1 Weierstrass function $\wp_e(x, e_1, e_2)$ (also DAMath) . . . 2249
31.5.2 Weierstrass function $\wp'_e(x, e_1, e_2)$ (also DAMath) . . . 2249
31.5.3 Inverse Weierstrass function $\wp_e^{-1}(y, e_1, e_2)$ (also DAMath) . . . 2249
31.5.4 Weierstrass Zeta function $\zeta_e(z, e_1, e_2)$ . . . 2250
31.5.5 Weierstrass Sigma function $\sigma_e(z, e_1, e_2)$ . . . 2250
31.6 Weierstrass elliptic functions, in terms of lattice half-periods ω_1 and ω_2 . . . 2251
31.6.1 Weierstrass function $\wp_\omega(z|\omega_1, \omega_2)$ . . . 2251
31.6.2 Weierstrass function, first derivative: $\wp'_\omega(z|\omega_1, \omega_2)$ . . . 2251
31.6.3 Inverse Weierstrass function $\wp_\omega^{-1}(z|\omega_1, \omega_2)$ . . . 2252
31.6.4 Weierstrass Zeta function $\zeta_\omega(z, \omega_1, \omega_2)$ . . . 2253
31.6.5 Weierstrass Sigma function $\sigma_\omega(z|\omega_1, \omega_2)$ . . . 2254

VII User library: numerical **2255**

32 Additional Classes **2256**

32.1 User defined functions based on multiple precision arithmetic (Python) . . . 2257
32.1.1 Overview . . . 2257
32.1.2 Double-precision arithmetic (`fpmlib`) . . . 2257
32.1.3 Binary floating-point in arbitrary-precision and with arbitrary exponent (`mpmlib`) . . . 2257
32.1.4 Interval arithmetic in arbitrary-precision and with arbitrary exponent (`ipmlib`) . . . 2257
32.1.5 Decimal floating-point in arbitrary-precision with limited exponent (`dpmlib`) . . . 2257
32.1.6 Rational numbers (quotients) in arbitrary-precision (`qpmlib`) . . . 2257
32.1.7 Binary floating-point in arbitrary-precision with limited exponent (`gpmlib`) . . . 2258
32.1.8 Binary balls in arbitrary-precision and with arbitrary exponent (`apmlib`) . . . 2258
32.2 User defined functions based on fixed precision arithmetic (C#) . . . 2259
32.2.1 Scalar functions with `Double` and `Complex`: `m53lib` and `m53libc` . . . 2260
32.2.2 Binary floating point, single precision: `slib` and `slibc` . . . 2261
32.2.3 Binary floating point, double precision: `dlib` and `dlibc` . . . 2262
32.2.4 Binary floating point, extended precision: `elib` and `elibc` . . . 2263
32.2.5 Binary floating point, quadruple precision: `qlib` and `qlib` . . . 2264
32.2.6 Binary floating point, octuple precision: `olib` and `olibc` . . . 2265
32.3 User defined functions based on arbitrary precision arithmetic (C#) . . . 2266
32.3.1 Binary floating point, multiple precision: `mlib`, `mlibc` . . . 2267
32.3.2 Binary floating point, single precision: `sflib` and `sflibc` . . . 2267
32.3.3 Binary floating point, double precision: `dflib` and `dflibc` . . . 2268
32.3.4 Binary floating point, extended precision: `eflib` and `eflibc` . . . 2269
32.3.5 Binary floating point, quadruple precision: `qflib` and `qflibc` . . . 2270
32.3.6 Binary floating point, octuple precision: `oflib` and `oflibc` . . . 2271
32.3.7 Binary floating point, multiple precision: `mflib`, `mflibc` . . . 2272
32.3.8 Binary arbitrary precision ball: `aflib` and `aflibc` . . . 2273
32.4 Scalar functions . . . 2274
32.4.1 Real and complex sine . . . 2274
32.4.2 Quadratic equation . . . 2275
32.4.3 Monic cubic equation . . . 2276
32.4.4 Cubic equation . . . 2277
32.4.5 Quartic equation . . . 2278
32.4.6 Transscribed from Julia: complex elliptic functions in double precision . . . 2279
32.4.7 Transscribed from Julia: complex hurwitz function, and related, in double precision . . . 2280
32.4.8 Speeedups for iterative algorithms which require an initial guess . . . 2281
32.4.9 Examples for matrix functions . . . 2282

33 Distribution functions **2283**

33.1 Distributions related to multiple comparisons of means . . . 2283
33.1.1 Normal maximum distribution, $\rho_{ij,i\neq j} = \rho$: pdf, cdf, qtf, boost class . . . 2283
33.1.2 Normal maximum modulus distribution, $\rho_{ij,i\neq j} = \rho$: pdf, cdf, qtf, boost class . . . 2285
33.1.3 Normal maximum distribution, $\rho_{ij,i\neq j} = \lambda_i\lambda_j$: pdf, cdf, qtf, boost class . . . 2286
33.1.4 Normal maximum modulus distribution, $\rho_{ij,i\neq j} = \lambda_i\lambda_j$: pdf, cdf, qtf, boost class . . . 2287
33.1.5 Normal range distribution: pdf, cdf, qtf, boost class . . . 2289
33.1.6 Studentized maximum distribution: pdf, cdf, qtf, boost class . . . 2290
33.1.7 Studentized maximum modulus distribution: pdf, cdf, qtf, boost class . . . 2291
33.1.8 Dunnett t-distribution, 1-sided: pdf, cdf, qtf, boost class . . . 2292
33.1.9 Dunnett t-distribution, 2-sided: pdf, cdf, qtf, boost class . . . 2293
33.1.10 Nair t-distribution: pdf, cdf, qtf, boost class . . . 2294
33.1.11 Halperin t-distribution: pdf, cdf, qtf, boost class . . . 2295
33.1.12 Studentized range distribution: pdf, cdf, qtf, boost class . . . 2296
33.2 Discrete (lattice) distribution functions related to (stratified) rank tests . . . 2297

33.2.1 Kendall S (or tau) distribution (under H_0), pmf vector . . . 2297
33.2.2 Mann-Whitney U distribution (under H_0), pmf vector . . . 2297
33.2.3 Jonckheere-Terpsta S distribution (under H_0), pmf vector . . . 2297
33.2.4 Spearman ρ distribution (under H_0), pmf vector . . . 2297
33.2.5 Sign test distribution (under H_0), pmf vector . . . 2298
33.2.6 Wilcoxon T distribution (under H_0), pmf vector . . . 2298
33.2.7 Page L distribution (under H_0), pmf vector . . . 2298
33.2.8 Quade L distribution (under H_0), pmf vector . . . 2299
33.3 Discrete (non-lattice) distribution functions related to rank tests . . . 2300
33.3.1 Cochran S distribution (under H_0), pmf vector . . . 2300
33.3.2 Friedman S distribution (under H_0), pmf vector . . . 2300
33.3.3 Quade S distribution (under H_0), pmf vector . . . 2300

34 Inferential statistics **2301**
34.1 Basic classical statistical tests (stratified) . . . 2301
34.1.1 Student t-test for 1 sample: tests (p-values) and confidence intervals . . . 2301
34.1.2 Student t-test for 1 sample: power calculations . . . 2304
34.1.3 Student t-test for 1 sample: sample size calculation . . . 2306
34.1.4 Chi-squared-test for the variance of 1 sample: tests (p-values) . . . 2307
34.1.5 Chi-squared-test for the variance of 1 sample: confidence intervals . . . 2308
34.1.6 Chi-squared-test for the variance of 1 sample: power . . . 2309
34.1.7 Chi-squared-test for the variance of 1 sample: sample size . . . 2310
34.2 Basic classical statistical tests for 2 independent samples (stratified) . . . 2311
34.2.1 Student t-test for 2 independent samples: tests (p-values) . . . 2311
34.2.2 Student t-test for 2 independent samples: confidence intervals . . . 2313
34.2.3 Student t-test for 2 independent samples: power . . . 2315
34.2.4 Student t-test for 2 independent samples: sample size calculation . . . 2317
34.2.5 Student t-test for 2 independent samples: power and sample size: failure to stratify . . . 2319
34.2.6 Student t-test for 2 independent samples: equivalence and non-inferiority . . . 2320
34.2.7 F-test for the variances of 2 independent samples: tests (p-values) . . . 2321
34.2.8 F-test for the variances of 2 independent samples: confidence intervals . . . 2323
34.2.9 F-test for the variances of 2 independent samples: power . . . 2325
34.2.10 F-test for the variances of 2 independent samples: sample size . . . 2327
34.3 Basic classical statistical tests for 2 correlated samples (stratified) . . . 2329
34.3.1 Student t-test for 2 correlated samples: tests (p-values) . . . 2329
34.3.2 Student t-test for 2 correlated samples: confidence intervals . . . 2331
34.3.3 Student t-test for 2 correlated samples: power . . . 2333
34.3.4 Student t-test for 2 correlated samples: sample size calculation . . . 2335
34.3.5 Morgan-Pitman test for the variances of 2 correlated samples: tests (p-values) . . . 2337
34.3.6 Morgan-Pitman test for the variances of 2 correlated samples: confidence intervals . . . 2339
34.3.7 Morgan-Pitman test for the variances of 2 correlated samples: power . . . 2341
34.3.8 Morgan-Pitman test for the variances of 2 correlated samples: sample size . . . 2343
34.3.9 Pearson's rho, 2 correlated samples: tests (p-values) . . . 2345
34.3.10 Pearson's rho, 2 correlated samples: confidence intervals . . . 2347
34.3.11 Pearson's rho, 2 correlated samples:: power . . . 2349
34.3.12 Pearson's rho, 2 correlated samples:: sample size calculation . . . 2351

Part I

Getting started

CHAPTER

ONE

SETUP AND GENERAL USAGE

XlCalcNet is a numerical library with parts written in Python and other parts written in C#, C++, C and Pascal, with focus on numerical calculations in multiple precision and data visualisation.

Since one of the main goals is to give access to software written in Python (or via PythonNet software written in C#) from within spreadsheet formulas, a dedicated CPython installation is strongly recommend, to make it easier to configure the interaction with Microsoft Excel and/or LibreOffice Calc, without disturbing existing Python installations.

The interaction with LibreOffice Calc is based on the fact that LibreOffice has built-in support for writing spreadsheet functions (which appear in the Function Wizard) in Python.

The interaction with Microsoft Excel is achieved by running a socket server written in Python, which is called from spreadsheet formulas using the functionality provided by Excel.Dna.

On the Python side XlCalcNet uses Mpmath 4.0 to provide a rich set of functions in arbitrary precision, using not only Mpmath's binary and interval data types, but also Python's built-in Decimal and Fraction data types. If GMP2 is installed, its data types can be used in many cases instead of Mpmath's binary data types, being much faster. Likewise, if Python-Flint is installed, its data types can be used in many cases instead of Mpmath's interval data types, being much faster, and often also more accurate.

On the C/C++ side, XlCalcNet uses DAMath, Boost Math, Boost Multiprecision and Eigen to provide numerical functions in single, double, extended, quadruple and octuple precision, which are available to the user both from C# and Python.

The XlCalcNet2 library, which is licensed under the LGPL-3.0 and is therefore provided as a separate project, is based on Boost Math, Boost Multiprecision, Eigen, GMP, MPFR, MPC and Flint and provides additional functions for the same fixed-precision data types as XlCalcNet and also in arbitrary precision.

XlCalcNet is intended to be used together with existing Python libraries like NumPy, Matplotlib, Pandas, SciPy. It can also be used from recent versions of RStudio and R, using the reticulate package.

1.1 Setting up XlCalcNet

1.1.1 Installing XlCalcNet

1.1.1.1 Installing a version of Python which is dedicated to MS Excel and/or LibreOffice Calc

The XlCalcNet package is compatible with Python versions 3.8 - 3.15. It is recommended to use a version of CPython which is both mature and supported. In this manual, we will use Python version 3.13.15.

> **Important**
>
> However, if we want to use XlCalcNet with LibreOffice (version 7.0 or later, 64 bit), we need to make sure that the version which we install is compatible with the main Python core installation of LibreOffice, which means that the first 2 numbers of the version number `x.y.z` must match.

To find out which version this is, follow these steps: In the folder `C:\Program Files\LibreOffice\program` double-click on `python.exe`. This opens the python console, which in the first line states which Python version is used. At the time of writing (October 2026), the most current version of LibreOffice is version 26.8, which uses Python version 3.13.15. Earlier version of LibreOffice use different versions of Python.

Python can be installed in different ways. It is recommended to install Python as a dedicated version for use with MS Excel and/or LibreOffice Calc, which does not require uninstalling any previous versions of Python, does not interfere with other Python installations, and does not require administrative privileges.

As installation folder any folder can be used for which the user has read and write access. In the following we will assume that the installation folder is `C:\Python313`. We assume that the path to this folder is NOT added to the PATH environment variable.

As an example of the installation process, we download the windows installer of version 3.13.15 (64 bit) from https://www.python.org/downloads/release/python-31315/. We will install this version into the folder `C:\Temp`, so we make sure beforehand that this folder exists and is empty.

In the Download folder, double-click on the downloaded file `python-3.13.15-amd64.exe` to start the installation. Click on "Customize installation".

In the next dialog page "Optional Features" unselect "Documentation", "Python test suite", "py launcher" and "for all users". Click on "Next".

In the next dialog page "Advanced Options" unselect all items, including "Create shortcuts". In the line below "Customize install location" enter `C:\Temp`. Click on `Install`. Once the installation has been completed, the last dialog page "Setup was successful" appears. Click on `Close`.

In the Windows explorer, navigate to the folder `C:\Temp`. Open another Windows explorer instance, navigate to `C:\`, and create the folder `C:\Python313`. Copy (DO NOT move!) the content of `C:\Temp` into `C:\Python313`.

Click the Start button and open **Settings** (or press `Windows Key + I`). Click on **Apps** on the left menu. Select **Installed apps** to view and manage all programs installed on your PC. Navigate to "Python 3.13.15 (64-bit)" and click on the `...` symbol. Select `Uninstall` and confirm. Once Uninstall has been completed, the last dialog page "Uninstall was successful" appears. Click on `Close`.

Now the folder `C:\Temp` can be deleted. The folder `C:\Python313` contains the ("freestanding") Python version that we will work with in this manual.

1.1.1.2 First steps with XlCalcNet

Since the path to `C:\Python313` is not added to the PATH environment variable, it is convenient to prepare, within the `C:\Python313` folder, batch files for the installation of the Python packages which one wishes to install and possibly update later.

The first batch file will ensure that our version of pip is up to date. Right-click over any free space in the `C:\Python313` folder, select `New -> Text Document`. Rename this document to `A01upgradepip.bat`, ignoring the warning. Open this file for editing in the

Windows standard editor. Type `python -m pip install -U --no-warn-script-location pip` as install command, begin a new line, type `pause`, save the file, and close the editor.

Now double-click on `A01upgradepip.bat`. This will update pip as needed.

In the same way prepare a batch file named `A02installxlcalcnet.bat`, using `python -m pip install -U xlcalcnet` as install command. Double-click on `A02installxlcalcnet.bat`. This will install the latest version of the XlCalcNet package.

To check that this installation was successful, double-click on `python.exe`, which will open the python console:

```
>>> from xlcalcnet import mpm
>>> mpm.dps = 40
>>> mpm.sqrt(2)
    mpf('1.4142135623730950488016887242096980785696621')
```

1.1.1.3 The 3 folders which are used by XlCalcNet

XlCalcNet uses the following 3 folders:

- The installation folder (in our example `C:\Python313\Lib\site-packages\xlcalcnet`), which contains the program code of the package (which should not be changed by the user during normal use). This folder is automatically created during the installation of XlCalcNet.
- The `DataXlCalcNet` folder in the Documents folder, which contains code examples and data which are directly manipulated by the user. This folder needs to created manually by the user (see below).
- The `XlCalcNetIDE` folder in the AppDataLocal folder, which contains data or executable binaries which are generated as a result of running a Python script or C# program. This folder is automatically created while using XlCalcNet.

Important

It is crucial for the correct functioning of XlCalcNetThat that the `DataXlCalcNet` folder is located in the Documents folder. The `DataXlCalcNet` folder has already been downloaded during the installation of XlCalcNet; it is located in the installation folder (in our example `C:\Python313\Lib\site-packages\xlcalcnet`). **The user needs to copy it manually from the installation folder into the Documents folder**.

1.1.1.4 Preparing the use of additional installation batch files for installing Python packages

The `DataXlCalcNet` folder contains a number of batch files for installing additional Python packages which can be used with XlCalcNet. These batch files are located in the subfolder `\PythonBatchFiles\BatchFiles`. The user can copy these batch files into the `C:\Python313` folder, and double-click on them to install the corresponding Python packages. The user can also create new batch files for installing additional Python packages, using the same procedure as described above for creating the batch files `A01upgradepip.bat` and `A02installxlcalcnet.bat`.

1.1.2 Installing and using Python.NET: Calling C# from Python

Python.NET is a package that gives Python programmers nearly seamless integration with the .NET Common Language Runtime (CLR) and provides a powerful application scripting tool for .NET developers. It allows Python code to interact with the CLR, and may also be used to embed Python into a .NET application.

See https://github.com/pythonnet/pythonnet

Assuming that the Python batch files have been installed as described *here*, Python.NET can be installed by double-clicking on the batch file `A03installpythonnet.bat` in the `C:\Python313` folder.

To check that this installation was successful, double-click on `python.exe`, which will open the python console. With Python.NET installed, we can access the C# module `qreal`, which provides functions in quadruple precision:

```
>>> from xlcalcnet import qreal
>>> qreal.sqrt(2)
    qreal('1.41421356237309504880168872420970')
```

Soem background information:

.NET Framework is part of the Microsoft Windows operating system since Windows Vista; .NET Framework 4.x can be installed since Windows XP. Recent versions of Windows (Windows 7 - Windows 11), which have been kept fully maintained, have .NET Framework 4.8 installed, which is the latest version of .NET Framework and will continue to be distributed with future releases of Windows. As long as it is installed on a supported version of Windows, .NET Framework 4.8 will continue to also be supported (see https://dotnet.microsoft.com/en-us/platform/support/policy/dotnet-framework).

As part of the .NET Framework 4.x runtime, 3 different compilers are provided: csc.exe (C#), vbc.exe (Visual Basic), and jsc.exe (JScript).

The 32 bit targeting versions are located in `C:\Windows\Microsoft.NET\Framework\v4.0.30319` and those for 64 bit in `C:\Windows\Microsoft.NET\Framework64\v4.0.30319`.

It is important to note that these compilers are not part of Visual Studio but part of Windows; they are, in a way, the closest to a compiler as part of the operating system that Windows has ever come up with. On the other hand, these compilers have been tugged away with the rest of the .NET Framework 4.x runtime; in that sense, they are "hidden" compilers.

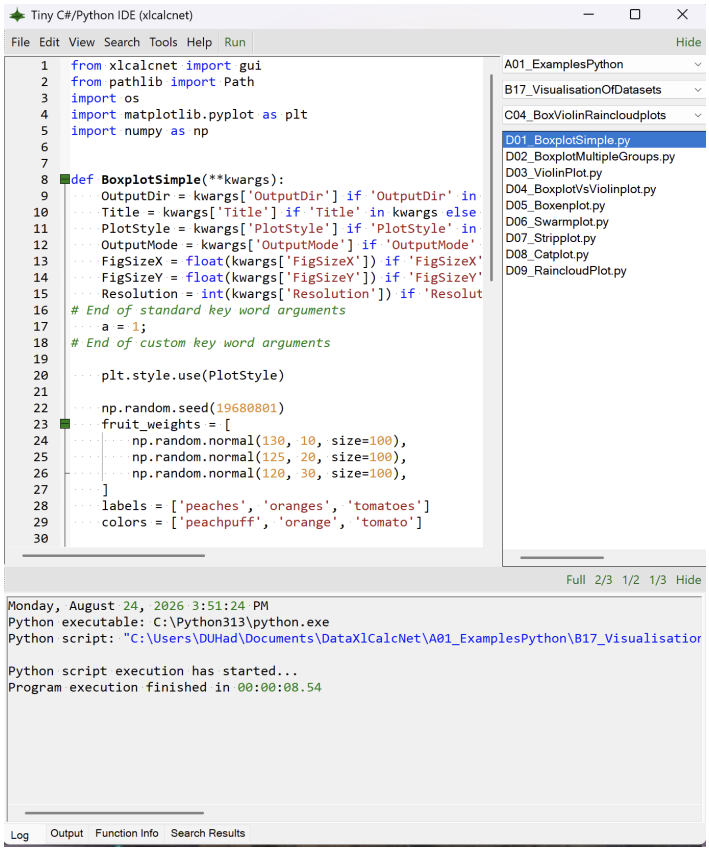
In the following, we will ignore the Visual Basic and JScript compilers, but focus only on C#. The C# compiler supports only language versions up to C# 5. Luckily, this still provides us with all language features which we need for our purposes.

In terms of usability, the .NET Framework 4.x runtime does not include an IDE; we therefore include a Tiny IDE as described below.

1.1.3 Installing and using the Tiny IDE as a Python application

1.1.3.1 Installation

With the `DataXlCalcNet` folder in the Documents folder and Python.NET installed, we can start using the "Tiny C#/Python IDE", which makes it easy to edit and run small programs written in Python or C#. The Tiny IDE is a Python program (it is started with `pythonw.exe`) which loads a UserControl written in C#. This is made possible by Python.NET.



Follow these steps to make the Tiny IDE available:

- In the Python installation folder, rightclick on `pythonw.exe`.
- Select `Create shortcut` -> Result: `pythonw.exe-Shortcut`. (On Windows 11: Select `Show more options` -> `Create shortcut` -> Result: `pythonw.exe-Shortcut`.)
- Rightclick on `pythonw.exe-shortcut`; Select Properties.
- In the dialogue Properties, select "Target", and type:`C:\Python313\pythonw.exe C:\Users\DUHad\Documents\DataXlCalcNet\A01_ExamplesPython\B01_GeneralUsage\C01_Setup\D03_ShowEditor.py`. Here the path to the documents folder (in our case `C:\Users\DUHad\Documents`) needs to be changed to meet the settings of your system. Then save.
- Rename `pythonw.exe-Shortcut` to `TinyIDE_Python313`
- Doubleclick on `TinyIDE_Python313`
- In the task-bar, right-click on the appearing Python symbol, and select "Pin to taskbar"

From now on, you can start the Tiny IDE by clicking on this Python symbol on the taskbar. To start an additional instance of the Tiny IDE when the Tiny IDE is already running, click in the main menu on `Tools` -> `Tiny IDE (external)`. Note that the Python source code for starting the Tiny IDE is also the Python code example which is shown after starting the Tiny IDE (in `A01_ExamplesPython\B01_GeneralUsage\C01_Setup\D03_ShowEditor.py`), so clicking on `Run` will also start an additional instance. However, now

the program does not return until it is closed, as it is not running in an additional instance of Python; running the program like this is useful for debugging and testing purposes, like modifying title, width and height of the window, which can be changed on lines 67-68.

1.1.3.2 Overview

The Tiny IDE is designed around the structure of the `DataXlCalcNet` folder, making it easy to navigate and manage existing code examples, as well a new code written by the user. The Tiny IDE can be used only to edit and run Python or C# code examples which are located in the `DataXlCalcNet` folder and are located in subfolders beginning with `A0`. The code examples are organized in a tree structure, which is shown in the top right panel (the "folder panel") of the Tiny IDE.

The top left panel (the "editor panel") of the Tiny IDE shows the code of the selected file, which can be edited and run. The Tiny IDE also provides features like syntax highlighting, autocompletion, bookmarks, code folding, and error highlighting to make coding easier.

The output of the program is shown in the bottom panel (the "output panel") of the Tiny IDE, which has 4 tabs: the "Log" tab, which documents the progress of compiling and running the code (and also displays warning and error messages); the "Output" tab, which shows the text output of the program (if any); the "Function Info" tab, which provides information about the functions (if they belong to a module from XlCalcNet); and the "Search Results" tab, which shows the search results.

Each file in the `DataXlCalcNet\A0*` folders can be opened in the Tiny IDE by clicking on it. Per Tiny IDE instance, only one file can be opened, edited and run at a time (to open an additional file, you need to start a new instance of the Tiny IDE: `Tools -> Tiny IDE (external)`). The Tiny IDE will load this file into the editor, and the code can be edited and run. To run the code, click on the "Run" button in the main menu. The output of the program (if any) is shown in the output tab of the output panel.

The ordering and naming of the code examples in the subfolders `A01_ExamplesPython` and `A02_ExamplesCSharp` matches the ordering and naming of the corresponding chapters, sections and subsections in this manual, making it easy to find the code example which corresponds to a specific section of the manual. In addition, the "section help" feature (`Help -> Section Help`), which is available in the main menu of the Tiny IDE and opens the corresponding section of this manual in a web browser, depends on this ordering and naming.

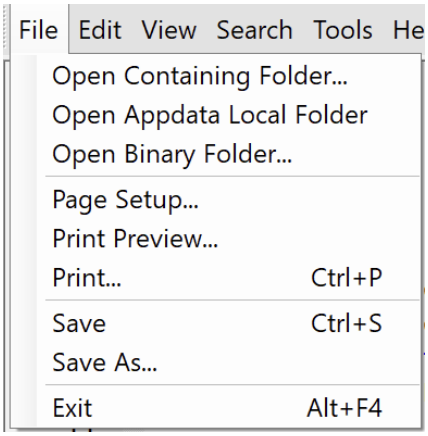
Also, in Python, the feature that code examples can be called like modules, using statements like `from A01_ExamplesPython.B17_VisualisationOfDatasets.C01_BarCharts import D01_BarChartPart1`, depends on keeping this ordering and naming intact.

Therefore the names of these folders and files should not be changed, and new code examples should be added to the appropriate folders, either `A03_UserlibPython` or `A04_UserlibCSharp` for user-defined libraries, or `A05_UserExamplesPython` or `A06_UserExamplesCSharp` for code examples which demonstrate the use of existing or user-defined libraries. The Tiny IDE will automatically detect new files and folders, and will update the tree structure accordingly.

1.1.3.3 The menu bar of the Editor

The Menubar of the Tiny IDE contains the following menus: `File`, `Edit`, `View`, `Search`, `Tools`, and `Help`. Each menu contains a number of items, which are described below.

There are also two buttons (with green foreground color) in the menu bar: the "Run" button, which runs the code of the current file, and the "Show/Hide" button, which toggles the visibility of the folder panel.



In the `File` menu, two standard items are missing: "New" and "Open".

The "New" item is missing because the Tiny IDE is designed to work within the `DataXlCalcNet` folder, and therefore new files which are not in the current folder should be created in the appropriate subfolders of `DataXlCalcNet`, which often have to be created manually first using the Windows Explorer.

There is, however, a `Save As` item in the file menu, which allows to save the current file under a new name in the current folder. This is useful for creating a copy of an existing file, and using this as a starting point for a new file.

The "Open" item (which would typically open a dialog box with the functionally of the Windows Explorer) is missing because the Tiny IDE is limited to the `DataXlCalcNet` folder. Instead the folder panel allows to navigate through the `DataXlCalcNet` folder and open any file in it.

Renaming or deleting files and folders is possible, but should be done with care, using the Windows Explorer, and not using the Tiny IDE. After these changes, when returning to the Tiny IDE, the tree structure will not be updated automatically, but has to be updated manually by clicking on the appropriate parent folder in the tree structure.

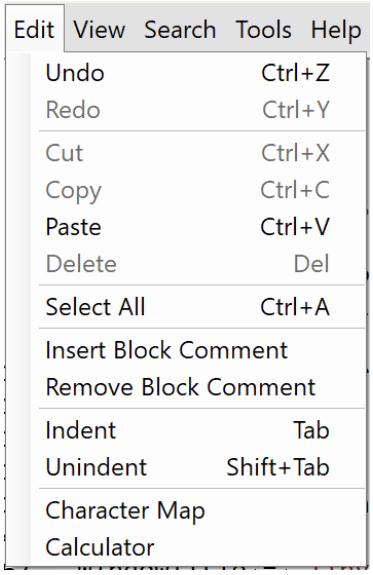
`Open Containing Folder` opens the Windows Explorer in the folder of the current file. This is useful for quickly accessing other files in the same folder, or for deleting files and folders.

`Open Appdata Local Folder` opens the Windows Explorer in the `AppData\Local\XlCalcNetIDE` folder. This is useful for quickly accessing files and folders which are generated by running Python or C# code examples in the Tiny IDE.

`Open Binary Folder` opens the Windows Explorer in the `Bin` subfolder of the `XlCalcNet` installation. This is useful mostly for debugging purposes.

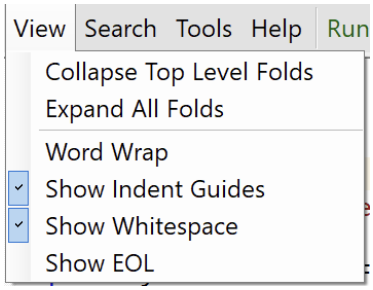
`Page Setup` opens the standard Windows dialog for setting up the page layout for printing. `Print Preview` opens a preview of the current file, which can be printed from there. `Print` opens the standard Windows dialog for printing the current file.

`Save` will just save the current file without any further action. `Save As` has been descibed above. `Exit` will close the Tiny IDE.



In the `Edit` menu, `Undo`, `Redo`, `Cut`, `Copy`, `Paste`, `Delete`, and `Select All` are standard items. `Insert BlockComment` and `Remove BlockComment` allows to comment or uncomment a block of code, which is useful for testing purposes (these 2 items are available in the context menu as well). `Indent` and `Unindent` allow to indent or unindent a block of code, which is useful for formatting purposes.

`Character Map` opens the standard Windows dialog for selecting special characters, which can be inserted into the code. `Calculator` opens the standard Windows calculator, which can be used for quick calculations.



In the `View` menu, `Collapse Top Level Folds` allows to collapse all top level folds in the code, which is useful for quickly navigating through the code.

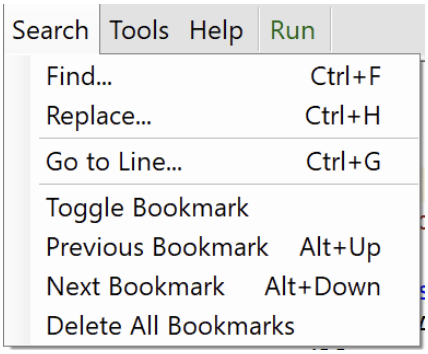
`Expand All Folds` allow to collapse or expand all folds in the code, which will make all code visible

`Show Indentation Guides` toggles the visibility of indentation guides in the editor panel.

`Word Wrap` toggles word wrap in the editor panel.

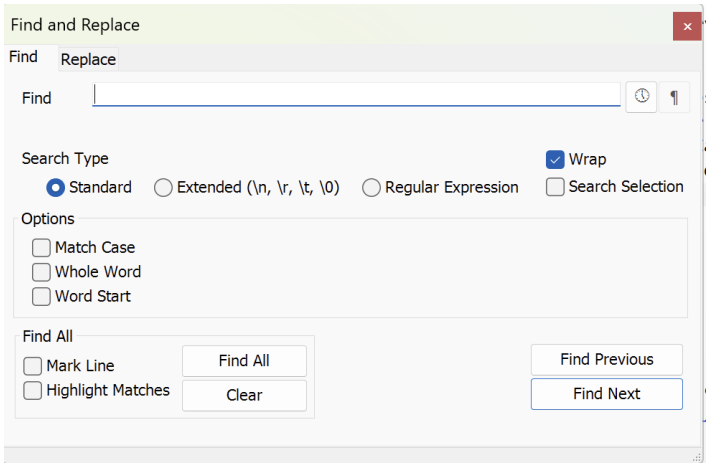
`Show Whitespace` toggles the visibility of whitespace characters in the editor panel.

`Show EOL` toggles the visibility of end of line markers in the editor panel.

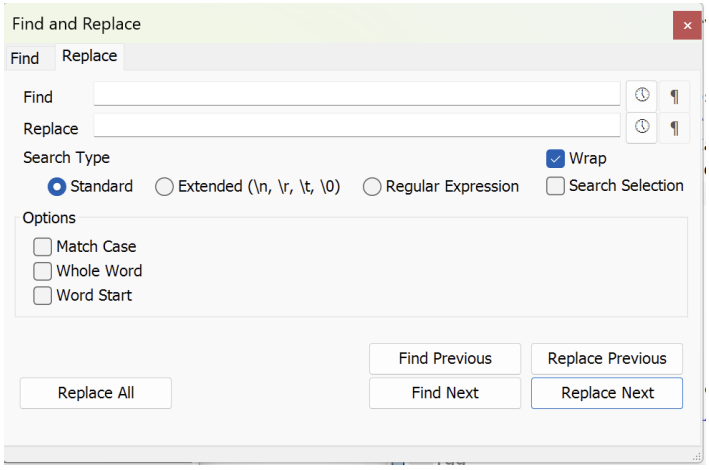


In the `Search` menu, `Find` starts the search for a string in the code, `Replace` allows to replace a string in the code, and `Goto` allows to jump to a specific line number in the code.

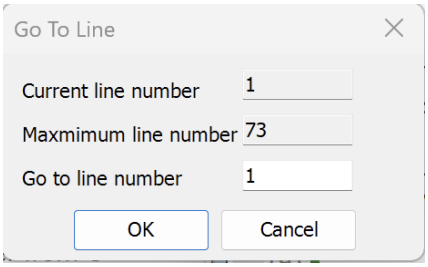
The corresponding dialog boxes are shown below:



If the string is found, the first occurrence is highlighted in the code. If the string is not found, a message box appears which informs that the string was not found. The search can be continued by clicking on `Find Next` or `Find Previous`. The search can be limited to the current selection, and it can be case sensitive or insensitive. The search can also be done using regular expressions.

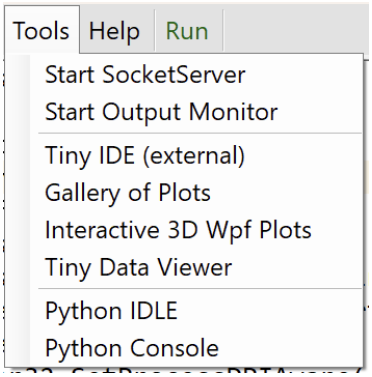


If the string is found, the first occurrence is highlighted in the code. If the string is not found, a message box appears which informs that the string was not found. The search can be continued by clicking on `Find Next` or `Find Previous`. `Replace Next`, `Replace Previous` or `Replace All` can be used to decide what to do with the found string. The search can be limited to the current selection, and it can be case sensitive or insensitive. The search can also be done using regular expressions.



if the line number is valid, the cursor jumps to the specified line number. If the line number is invalid, a message box appears which informs that the line number is invalid.

`Toggle Bookmark` allows to set or delete a bookmark in the code, which can be used to quickly navigate through the code. `Delete All Bookmarks` deletes all bookmarks in the code. `Next Bookmark` jumps to the next bookmark in the code. `Previous Bookmark` jumps to the previous bookmark in the code.



In the `Tools` menu, `Start Socket Server` starts the socket server, see *here* for details.

`Start Output Monitor` starts the output monitor application, see *here* for details.

`Tiny IDE (external)` starts an additional instance of the Tiny IDE, which can be used to edit and run another file.

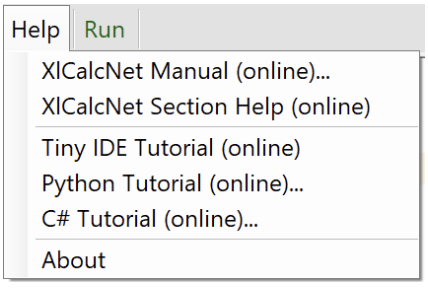
`Gallery of Plots` starts the gallery of plots application, see *here* for details.

`Interactive 3D Wpf Plots` starts the Interactive 3D Wpf Plots application, see *here* for details.

`Tiny Data Viewer` starts the Tiny Data Viewer application, see *here* for details.

`Python IDLE` starts the Python IDLE application.

`Python Console` starts the Python console.



In the `Help` menu, `XlCalcNet Manual (online)...` displays the start page of the XlCalcNet online manual in a web browser.

`XlCalcNet Section Help (online)...` displays the section of the XlCalcNet.online manual which corresponds to the current file in a web browser.

`Tiny IDE Tutorial (online)...` displays the section of the XlCalcNet.online manual which explains the use of the Tiny IDE in a web browser.

`Python Tutorial (online)...` displays the online tutorial for Python, which is available on the official Python website in a web browser.

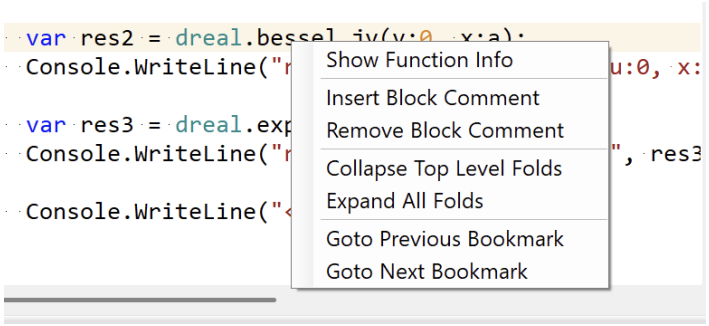
`C\# Tutorial (online)...` displays the online tutorial for C#, which is available on the official C# website in a web browser.

`About XlCalcNet...` displays information about the XlCalcNet package, including version number and copyright information.

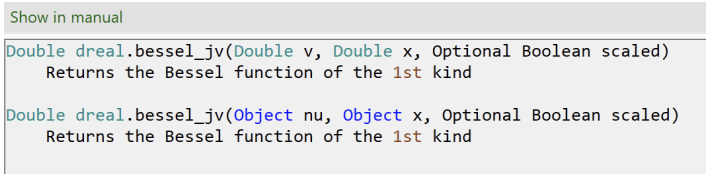
1.1.3.4 The context menu of the editor

Right-clicking in the editor panel opens a context menu, which provides quick access to common actions like `Insert Block`, `Remove Block Comment`, `Collapse Top Level Folds`, `Expand All Folds`, `Goto Previous Bookmark`, `Goto Next Bookmark`, all of which are also available in the main menu.

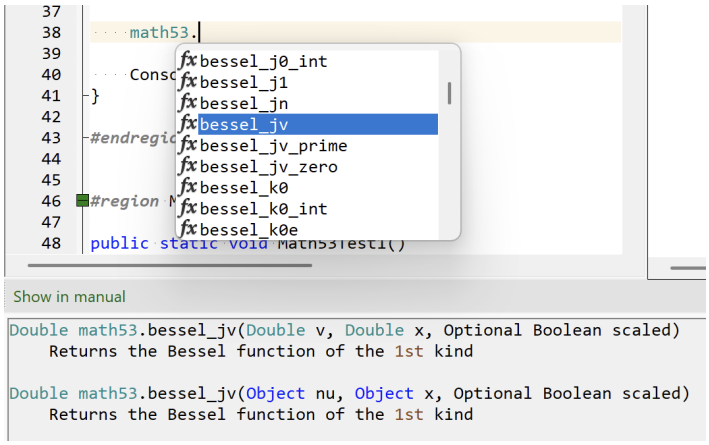
New in this context menu is the item `Show Function Info`, which for functions which belong to a module from XlCalcNet, displays information about the function in the "Function Info" tab of the output panel.



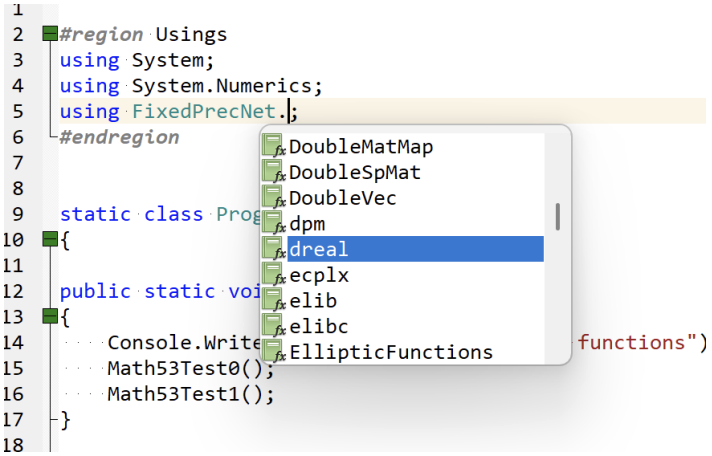
In the screenshot above, the context menu is shown after right-clicking on the function `dreal.bessel_jv` (with the curser to the right of the dot). The item `Show Function Info` is highlighted, and the corresponding information about this function is shown in the "Function Info" tab of the output panel below.



Just to the upper left of the `Show Function Info` item, the button `Show in Manual` is visible. Clicking on this button opens the corresponding section of the XlCalcNet online manual in a web browser.



This works in combination with the autocomplete feature, which is activated by pressing `Ctrl + Space`. The autocomplete feature shows a list of functions which belong to a module from XlCalcNet, and for each function, the corresponding information is shown in the "Function Info" tab of the output panel. This allows to quickly find the function which is needed, and to see how it can be used.



The autocomplete feature also works for user-defined libraries, however in these cases no additional information is shown in the "Function Info" tab of the output panel.

1.1.3.5 The Python development cycle in the Tiny IDE

Here we describe the Python development cycle in the Tiny IDE for producing and running python programs. The process for producing a Python library is similar but different, and is described *here*.

Overall, the Python development cycle in the Tiny IDE consists of the following steps: The file is opened in the editor panel, and the code is edited as needed. The code can be run by clicking on the "Run" button in the main menu bar. If there are any errors or warnings, they are shown in the "Log" tab of the output panel. When clicking on the error messages in the "Log" tab, they are also highlighted in the code. After correcting the errors, the "Run" button can be clicked again. If there are no errors, the code is is executed. Any text output of the program is shown in the "Output" tab of the output panel after the program has finished running.

These steps are illustrated in the following screenshots, which show the Python development cycle in the Tiny IDE for producing and running python programs.

```
 1
 2  # See: https://python-graph-gallery.
 3
 4  from xlcalcnet import gui
 5  from pathlib import Path
 6  import os, time
 7  import seaborn as sns
 8  import pandas as pd
 9
10
11  def KdePlot3(**kwargs):
56  try:
64  except Exception:
```

Directly after loading the Python code example, the code is folded, and the “Log” tab of the output panel is empty. The “Output” tab of the output panel is also empty, since the program has not been run yet. The unfolded code looks like this:

```
# See: https://python-graph-gallery.com/80-contour-plot-with-seaborn/

from xlcalcnet import gui
from pathlib import Path
import os, time
import seaborn as sns
import pandas as pd

def KdePlot3(**kwargs):
    OutputDir = kwargs['OutputDir'] if 'OutputDir' in kwargs else 'OutputMonitor'
    Title = kwargs['Title'] if 'Title' in kwargs else 'KdePlot3'
    PlotStyle = kwargs['PlotStyle'] if 'PlotStyle' in kwargs else 'default'
    OutputMode = kwargs['OutputMode'] if 'OutputMode' in kwargs else 'svg'
    FigSizeX = float(kwargs['FigSizeX']) if 'FigSizeX' in kwargs else 4
    FigSizeY = float(kwargs['FigSizeY']) if 'FigSizeY' in kwargs else 4
    Resolution = int(kwargs['Resolution']) if 'Resolution' in kwargs else 300
# End of standard key word arguments

    # Choose 'Agg' as backend unless we want to display the graphics
    if (OutputMode != 'gui'):
        import matplotlib
        matplotlib.use('Agg')
    import matplotlib.pyplot as plt
    plt.style.use(PlotStyle)

    fn = gui.get_dataxlcalcnet()
    fn += r'\DataExamples\MainExamples\Workbooks\Datasets.xlsx'
    datasets = pd.ExcelFile(fn)
    df = pd.read_excel(datasets, 'iris')

    sns.set_style('white')
    sns.kdeplot(x=df.sepal_width, y=df.sepal_length,
                cmap='Blues', fill=True, bw_adjust=0.5)

    fig = plt.gcf()
    fig.tight_layout()

# Start of output choices
    if (OutputMode == 'plt'):
        plt.show()
    elif (OutputMode == 'gui'):
        gui.plot(fig, __file__, Title)
    else:
```

(continues on next page)

(continued from previous page)

```
        FName = 'Temp'
        if OutputDir != 'Temp': FName = (Path(__file__).stem)
        LocalDir = gui.get_local_appdata_xlcalcnet()
        FullPath = os.sep.join([LocalDir, OutputDir, FName + '.' + OutputMode])
        plt.savefig(FullPath,  bbox_inches='tight')
        if OutputDir != 'Temp': print('Graphics written to: ', FullPath)
    plt.close('all')

try:
    if __name__ == '__main__':
        start0 = time.time()
        KdePlot3(OutputMode = 'gui')
        end0 = time.time()
        print('Elapsed time:', format(end0 - start0, '.4g'), 'seconds' )

except Exception:
    import traceback
    print(traceback.format_exc())
```

Folding in Python works on code blocks which are defined by indentation. At the top of the file are the import statements, followed by a `def funcname(**kwargs)` statement, where "funcname" in this case is `KdePlot3`. The body of this function is the place where "the real work" is done.

This function also has two standardized parts (for Matplotlib graphic code examples), one at the beginning, which takes care of the keyword arguments and ensures that the 'Agg' backend is used unless one wants to display the graphics (this is necessary to ensure this function can be called from older versions of Libreoffice like 7.4); and another at the end ("# Start of output choices"), which makes sure that interactive use, output to the OutputMonitor folder, or output to another folder is possible in verious formats (like jpg, png, svg, pdf).

At the end of the file, the `try ... except` block makes sure that exceptions are dealt with properly, that the time for actually running the code (as opposed to the time required to load and initialize the imported libraries) is printed, and that we have the chance to call the function with a specific set of keyword arguments (in this case `OutputMode = 'gui'`).

Python files with this overall structure are well suited for calls from within spreadsheet functions.

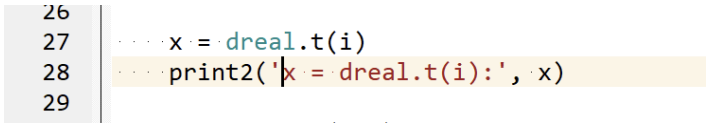
```
  1
  2 <H1 Title="General assignments and conversions">
 17 <H1 Title="Functions with argument conversion">
 32 <H1 Title="Arithmetic operators with dreal">
 45 <H1 Title="Arithmetic operators with floats">
 57 <H1 Title="Arithmetic operators with (long) integers">
 70 <H1 Title="Arithmetic operators with (short) integers">
 81 <H1 Title="Arithmetic comparisons with dreal">
 98 <H1 Title="Arithmetic comparisons with floats">
114 <H1 Title="Arithmetic comparisons with (long) integers">
131 <H1 Title="Arithmetic comparisons with (short) integers">
147 <H1 Title="Assignments to matrices">
149
```

The output of the program is shown in the "Output" tab of the output panel after the program has finished running. Lengthy text output can be folded and unfolded, and the context menu allows to copy the output to the clipboard, clear the output, or save the output to a file.

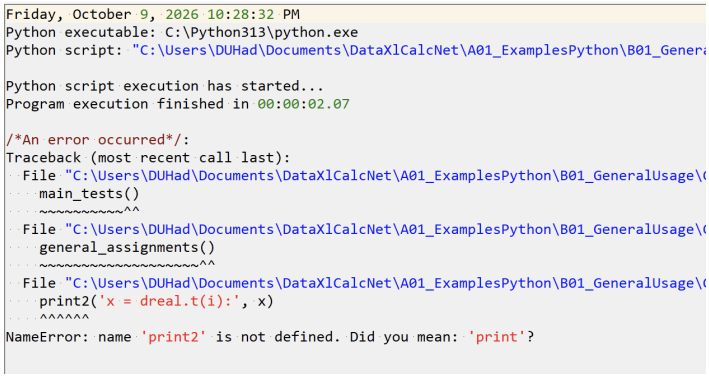
```
Saturday, October 10, 2026 7:49:52 AM
Python executable: C:\Python313\python.exe
Python script: "C:\Users\DUHad\Documents\DataXlCalcNet\

Python script execution has started...
Program execution finished in 00:00:07.33
```

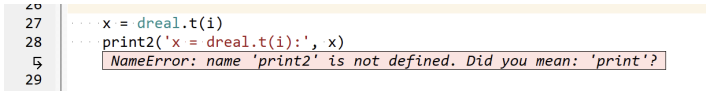
The "Log" tab of the output panel contains additional information after successfully running the program.



The snapshot above shows a code snippet which contains an error (`print` is misspelled as print2``)



This error is detected by the Python interpreter, and is reported in the Log tab of the output panel.



After double-clicking in the Log tab on the first line in red color, the error is also indicated in the editor, with a full error message below the line where the error occured.

1.1.3.6 The CSharp development cycle in the Tiny IDE

Here we describe the C# development cycle in the Tiny IDE for producing `*.exe` files which are stored in the `AppData\Local\XlCalcNetIDE\Bin` folder, and which can be run immediately. The process for producing `*.dll` files which can be called from Python is similar but different, and is described *here*.

Overall, the C# development cycle in the Tiny IDE consists of the following steps: The file is opened in the editor panel, and the code is edited as needed. The code can be compiled by clicking on the "Run" button in the main menu bar. If there are any errors or warnings, they are shown in the "Log" tab of the output panel. When clicking on the error messages in the "Log" tab, they are also highlighted in the code. After correcting the errors, the "Run" button can be clicked again to compile the code. If there are no errors, the code is compiled into a `*.exe` file, which is stored in the `AppData\Local\XlCalcNetIDE\Bin` folder and which is executed automatically after successful compilation. Any text output of the program is shown in the "Output" tab of the output panel after the program has finished running.

These steps are illustrated in the following screenshots, which show the C# development cycle in the Tiny IDE for producing `*.exe` files:

```
#region Usings

 static class Program
{

 public static void MainTests()
{
    Console.WriteLine("Demo of some scplx functions");
    ScplxTest0();
    ScplxTest1();
}

#region ScplxTest0

#region ScplxTest1

 /* This region contains the program entry point. Do not change */
#region Main

}

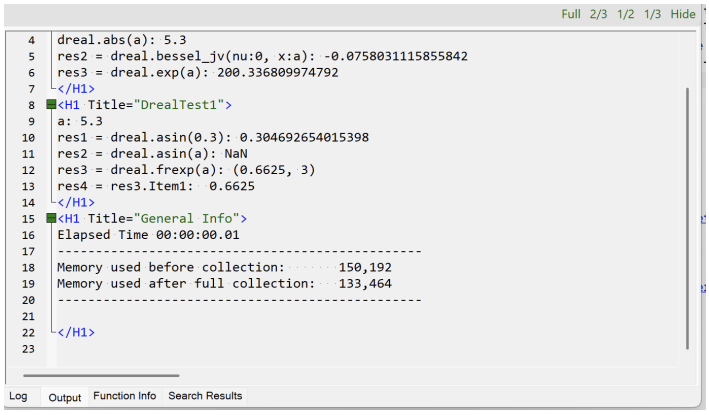
 /* Do not remove. Do not add anything after this */
#region EOF
```

Directly after loading the C# code example, the code is folded, and the "Log" tab of the output panel is empty. The "Output" tab of the output panel is also empty, since the program has not been run yet.

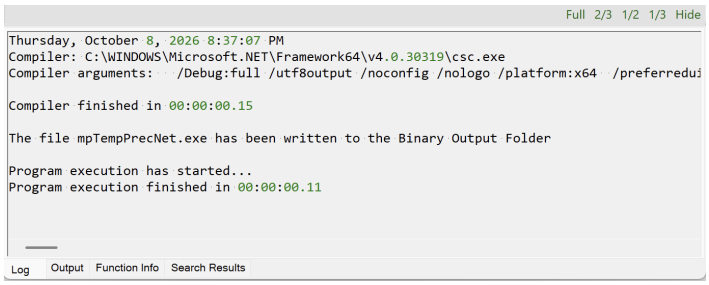
Folding in C# works both on regions and on code blocks. Overall, the folding of regions is more important than the folding of code blocks, since it allows to hide the implementation of functions and classes, and to focus on the overall structure of the code. The folding of code blocks is useful for hiding the implementation of loops and conditional statements, and to focus on the overall structure of the code.

The screenshot above shows the overall structure of the C# code examples in XlCalcNet, which are organized into regions. The first region contains the using statements, followed (outside of any region) by a `static class Program` statement, and the first function in this class, which always has the form `public static void MainTests()`. The body of this function contains calls to the functions where "the real work" is done.

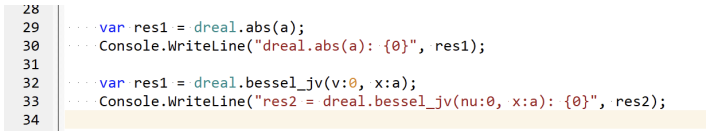
The implementations of these functions are located in the following regions (in this example the regions "ScplxTest0" and "ScplxTest1"), which are organized according to the functionality of the functions. The next region is called "Main", and contains the implementation of the `Main` function, which is the entry point of the program, and contains a lot of necessary boilerplate code, which makes sure that the program can run without a project file (which Visual Studio would require). The last region is called "EOF", and makes sure that code folding is working properly (adressing a small bug in the underlying ScintillaNet library). These last two regions should never be changed by the user during normal use.



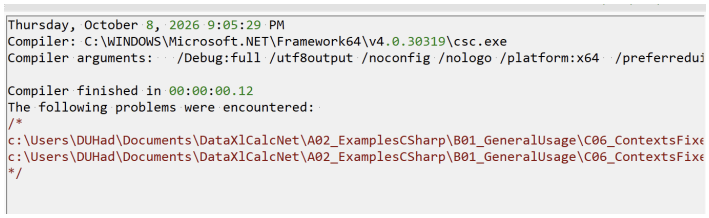
The output of the program is shown in the "Output" tab of the output panel after the program has finished running. The output can be folded and unfolded, and the context menu allows to copy the output to the clipboard, clear the output, or save the output to a file.



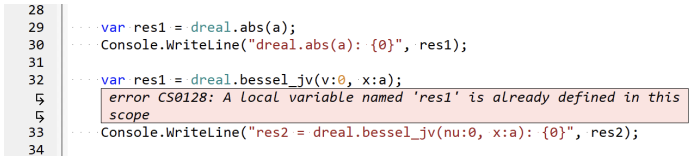
The “Log” tab of the output panel contains additional information after successfully compiling and running the program.



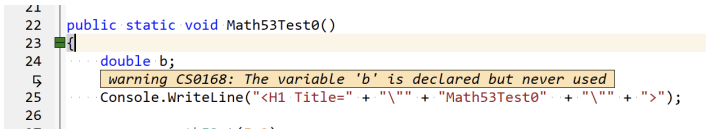
The snapshot above shows a code snippet which contains an error (the variable `res1` is defined twice)



This error is detected by the compiler, and is reported in the Log tab of the output panel.



After double-clicking in the Log tab on the first line in red color, the error is also indicated in the editor, with a full error message below the line where the error occured.

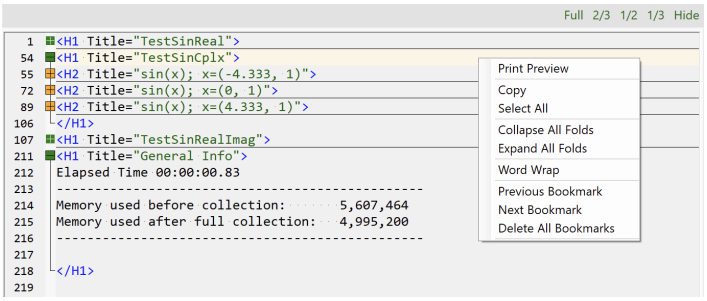


Warnings are treated in a way similar to errors: in this case the program is compiled (in the absence of errors), but is not run. Instead the warning is shown in the Log tab, and after double-clicking on it the warning is also indicated in the editor, with a full error message below the line where the warning was triggered.

1.1.3.7 The Output tab in the Output Panel

Describe the toolbar on top of the Output tab.

Note that the Output tab in the Output Panel can be used to display any text output of a Python or C# program. The output can be folded and unfolded, and the context menu allows to copy the output to the clipboard, clear the output, or save the output to a file.



1.1.3.8 Source code

The Python source code for starting the IDE can be found here: https://github.com/duhadler/XlCalcNet/blob/master/xlcalcnet/ShowEditor.py

The C# source code for the IDE can be found here: https://github.com/duhadler/XlCalcNet/tree/master/xlcalcnet/Addin/NET48/Source/TinyEditor

1.1.4 Installing and using Numpy, Matplotlib, Pandas, Scipy, Seaborn, Statsmodels and Scikit-learn

1.1.4.1 Numpy

Numpy is "The fundamental package for scientific computing with Python". For more information, see https://numpy.org/ and https://en.wikipedia.org/wiki/NumPy.

Assuming that the Python batch files have been installed as described *here*, Numpy can be installed by double-clicking on the batch file `A04installnumpy.bat` in the `C:\Python313` folder.

The following example shows how Numpy can be used with the Decimal type to calculate the mean:

```
import numpy as np
from xlcalcnet import dpm

def demo_mp():
    r = 8
    c = 2
    dpm.dps = 30
    R = np.ndarray((r,c),dtype=dpm.realtype)
    d1 = dpm.t(1.0)
    for i in range(r):
        for j in range(c):
            R[i,j] = 10*(i+1) + d1/(j+7)
    print(R)
    print()
    res = np.mean(R)
    print("res = np.mean(R): \n", res, type(res))
    print()
    res = np.mean(R, axis=0)
    print("res = np.mean(R, axis=0): \n", res, type(res))
    print()
    res = np.mean(R, axis=1)
    print("res = np.mean(R, axis=1): \n", res, type(res))

def demo_all():
    demo_mp()

demo_all()
```

The output looks like this:

```
[[Decimal('10.1428571428571428571428571429') Decimal('10.125')]
 [Decimal('20.1428571428571428571428571429') Decimal('20.125')]
 [Decimal('30.1428571428571428571428571429') Decimal('30.125')]
 [Decimal('40.1428571428571428571428571429') Decimal('40.125')]
 [Decimal('50.1428571428571428571428571429') Decimal('50.125')]
 [Decimal('60.1428571428571428571428571429') Decimal('60.125')]
 [Decimal('70.1428571428571428571428571429') Decimal('70.125')]
 [Decimal('80.1428571428571428571428571429') Decimal('80.125')]]

res = np.mean(R):
 45.133928571428571428571428571 <class 'decimal.Decimal'>

res = np.mean(R, axis=0):
 [Decimal('45.142857142857142857142857143') Decimal('45.125')] <class 'numpy.ndarray'>

res = np.mean(R, axis=1):
 [Decimal('10.133928571428571428571428571')
 Decimal('20.133928571428571428571428571')
 Decimal('30.133928571428571428571428571')
 Decimal('40.133928571428571428571428571')
 Decimal('50.133928571428571428571428571')
 Decimal('60.133928571428571428571428571')
```

(continues on next page)

(continued from previous page)

```
Decimal('70.133928571428571428571428571')
Decimal('80.133928571428571428571428571')] <class 'numpy.ndarray'>
```

1.1.4.2 Matplotlib

Matplotlib is "a comprehensive library for creating static, animated, and interactive visualizations in Python". For more information, see https://matplotlib.org/ and https://en.wikipedia.org/wiki/Matplotlib.

Assuming that the Python batch files have been installed as described *here*, Matplotlib can be installed by double-clicking on the batch file `A05installmatplotlib.bat` in the `C:\Python313` folder.

The following example shows how Matplotlib can be used to produce a boxplot. This code example shows how parameters can be passed:

The Python code for the example below can also be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D04b_Matplotlib3D.py.

```
from xlcalcnet import gui
import os, re
import numpy as np
import mpl_toolkits.mplot3d.axes3d as axes3d
import matplotlib.pyplot as plt

def ProjectFilledContour(**kwargs):
    OutputDir = kwargs['OutputDir'] if 'OutputDir' in kwargs else 'OutputMonitor'
    Title = kwargs['Title'] if 'Title' in kwargs else 'ProjectFilledContour'
    PlotStyle = kwargs['PlotStyle'] if 'PlotStyle' in kwargs else 'default'
    OutputMode = kwargs['OutputMode'] if 'OutputMode' in kwargs else 'gui'
    FigSizeX = float(kwargs['FigSizeX']) if 'FigSizeX' in kwargs else 4
    FigSizeY = float(kwargs['FigSizeY']) if 'FigSizeY' in kwargs else 4
    Resolution = int(kwargs['Resolution']) if 'Resolution' in kwargs else 300
# End of standard key word arguments

    plt.style.use(PlotStyle)

    fig = plt.figure()
    ax = fig.add_subplot(projection='3d')
    X, Y, Z = axes3d.get_test_data(0.05)

    # Plot the 3D surface
    ax.plot_surface(X, Y, Z, edgecolor='royalblue', lw=0.5, rstride=8, cstride=8,
                    alpha=0.3)

    # Plot projections of the contours for each dimension.  By choosing offsets
    # that match the appropriate axes limits, the projected contours will sit on
    # the 'walls' of the graph
    ax.contourf(X, Y, Z, zdir='z', offset=-100, cmap='coolwarm')
    ax.contourf(X, Y, Z, zdir='x', offset=-40, cmap='coolwarm')
    ax.contourf(X, Y, Z, zdir='y', offset=40, cmap='coolwarm')

    ax.set(xlim=(-40, 40), ylim=(-40, 40), zlim=(-100, 100),
           xlabel='X', ylabel='Y', zlabel='Z')
    fig.tight_layout()

# Start of output choices
    if (OutputMode == 'gui'):
        gui.plot(fig, __file__, Title)
    else:
        FName = 'Temp'
        if OutputDir != 'Temp': FName = re.sub('[^a-zA-Z0-9]', '', Title)
        LocalDir = gui.get_local_appdata_xlcalcnet()
        FullPath = os.sep.join([LocalDir, OutputDir, FName])
        plt.savefig(FullPath + '.' + OutputMode,  bbox_inches='tight')
    plt.close('all')

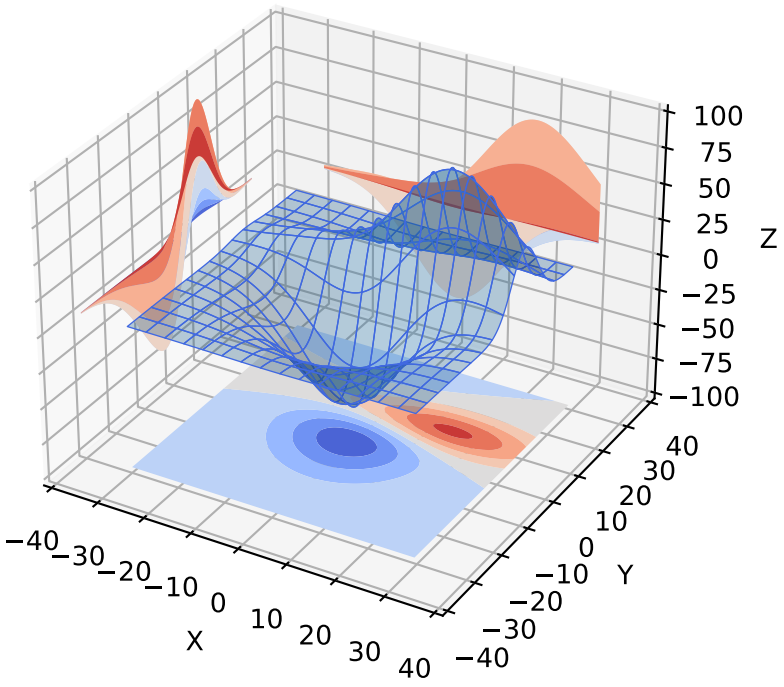
try:
    if __name__ == '__main__':
        ProjectFilledContour()
```

(continues on next page)

(continued from previous page)

```
except Exception:
    import traceback
    print(traceback.format_exc())
```

This produces the following output:



1.1.4.3 Pandas

Pandas is "a fast, powerful, flexible and easy to use open source data analysis and manipulation tool, built on top of the Python programming language". For more information, see https://pandas.pydata.org/ and https://en.wikipedia.org/wiki/Pandas_(software)

Assuming that the Python batch files have been installed as described *here*, Pandas can be installed by double-clicking on the batch file `A06installpandas.bat` in the `C:\Python313` folder.

The following example shows how Pandas can be used to access data in an Excel workbook:

```
import time
import pandas as pd

def main_tests():
    get_irisdata()

def get_documents_folder():
    """Returns the documents folder."""
    import ctypes, ctypes.wintypes
    buf = ctypes.create_unicode_buffer(ctypes.wintypes.MAX_PATH)
    ctypes.windll.shell32.SHGetFolderPathW(None, 0x0005, None, 0, buf)
    return str(buf.value)

def get_irisdata():
    fn = get_documents_folder()
    fn += r'\DataXlCalcNet\DataExamples\MainExamples\Workbooks\Datasets.xlsx'
    datasets = pd.ExcelFile(fn)
    df = pd.read_excel(datasets, 'iris')
    print(df)
    print(df.head(8))
    print(df.dtypes)

try:
    if __name__ == '__main__':
        start0 = time.time()
        main_tests()
        end0 = time.time()
        print('Elapsed time:', format(end0 - start0, '.4g'), 'seconds' )

except Exception:
    import traceback
    print(traceback.format_exc())
```

The output looks like this:

```
     Sepal.Length  Sepal.Width  Petal.Length  Petal.Width    Species
0             5.1          3.5           1.4          0.2     setosa
1             4.9          3.0           1.4          0.2     setosa
2             4.7          3.2           1.3          0.2     setosa
3             4.6          3.1           1.5          0.2     setosa

1.1.4.4 Scipy

Scipy is "a fast, powerful, flexible and easy to use open source data analysis and manipulation tool, built on top of the Python programming language". For more information, see https://scipy.org/ and https://en.wikipedia.org/wiki/SciPy.

Assuming that the Python batch files have been installed as described *here*, Scipy can be installed by double-clicking on the batch file `A07installscipy.bat` in the `C:\Python313` folder.

The following example shows how Scipy can be used for fitting data:

```
import numpy as np
import matplotlib.pyplot as plt
from scipy.optimize import curve_fit

def func(x, a, b, c):
    return a * np.exp(-b * x) + c

def test_curvefit():
    # See https://docs.scipy.org/doc/scipy/reference/generated/scipy.optimize.curve_fit.html
    print('Hello from test_curvefit!')

    xdata = np.linspace(0, 4, 50)
    y = func(xdata, 2.5, 1.3, 0.5)
    rng = np.random.default_rng()
    y_noise = 0.2 * rng.normal(size=xdata.size)
    ydata = y + y_noise
    plt.plot(xdata, ydata, 'b-', label='data')

    popt, pcov = curve_fit(func, xdata, ydata)
    print(popt)
    plt.plot(xdata, func(xdata, *popt), 'r-',
             label='fit: a=%5.3f, b=%5.3f, c=%5.3f' % tuple(popt))

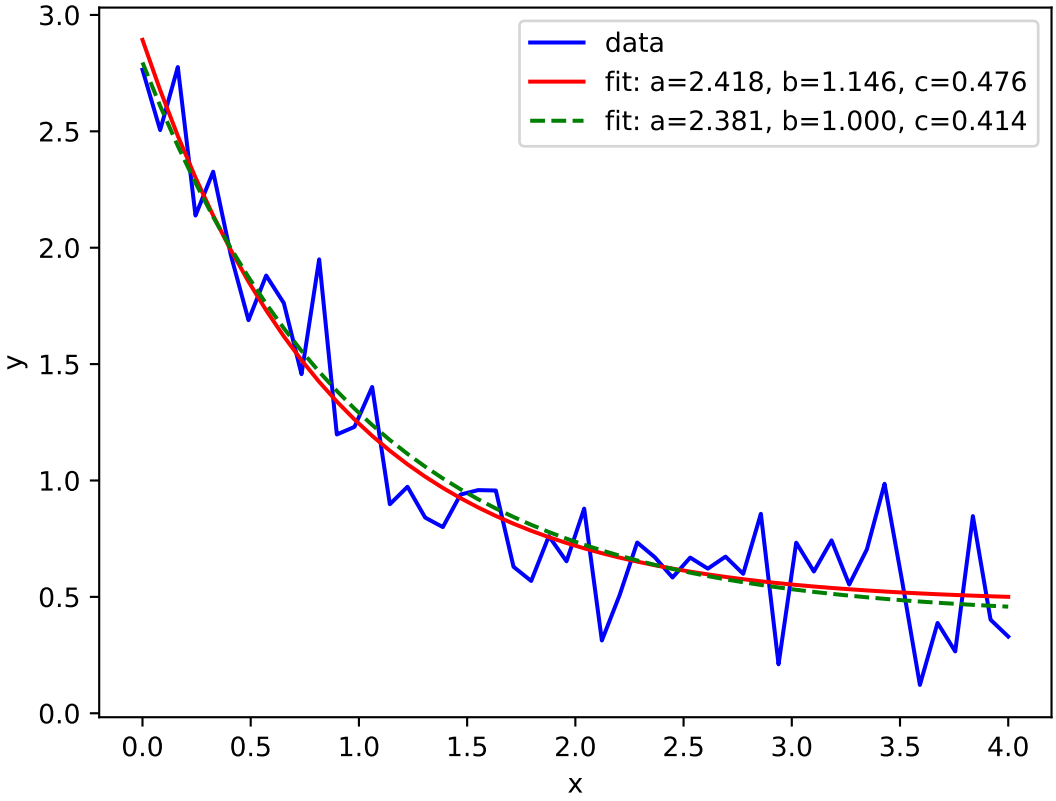
    popt, pcov = curve_fit(func, xdata, ydata, bounds=(0, [3., 1., 0.5]))
    print(popt)
    plt.plot(xdata, func(xdata, *popt), 'g--',
             label='fit: a=%5.3f, b=%5.3f, c=%5.3f' % tuple(popt))

    plt.xlabel('x')
    plt.ylabel('y')
    plt.legend()
    plt.show()

try:
    print()
    test_curvefit()

except Exception:
    import traceback
    print(traceback.format_exc())
```

This produces the following output:



data
fit: a=2.418, b=1.146, c=0.476

1.1.4.5 Seaborn

Seaborn is "a Python data visualization library based on matplotlib. It provides a high-level interface for drawing attractive and informative statistical graphics". For more information, see https://seaborn.pydata.org/.

Assuming that the Python batch files have been installed as described *here*, Seaborn can be installed by double-clicking on the batch file `A08installseaborn.bat` in the `C:\Python313` folder.

The following example shows how Seaborn can be used to produce a scatterplot matrix:

```
from xlcalcnet import gui
from pathlib import Path
import os
import seaborn as sns
import matplotlib.pyplot as plt

# See also: https://seaborn.pydata.org/examples/scatterplot_matrix.html

def ScatterplotMatrix(**kwargs):
    OutputDir = kwargs['OutputDir'] if 'OutputDir' in kwargs else 'OutputMonitor'
    Title = kwargs['Title'] if 'Title' in kwargs else 'ScatterplotMatrix'
    PlotStyle = kwargs['PlotStyle'] if 'PlotStyle' in kwargs else 'default'
    OutputMode = kwargs['OutputMode'] if 'OutputMode' in kwargs else 'svg'
    FigSizeX = float(kwargs['FigSizeX']) if 'FigSizeX' in kwargs else 4
    FigSizeY = float(kwargs['FigSizeY']) if 'FigSizeY' in kwargs else 4
    Resolution = int(kwargs['Resolution']) if 'Resolution' in kwargs else 300
# End of standard key word arguments

    plt.style.use(PlotStyle)

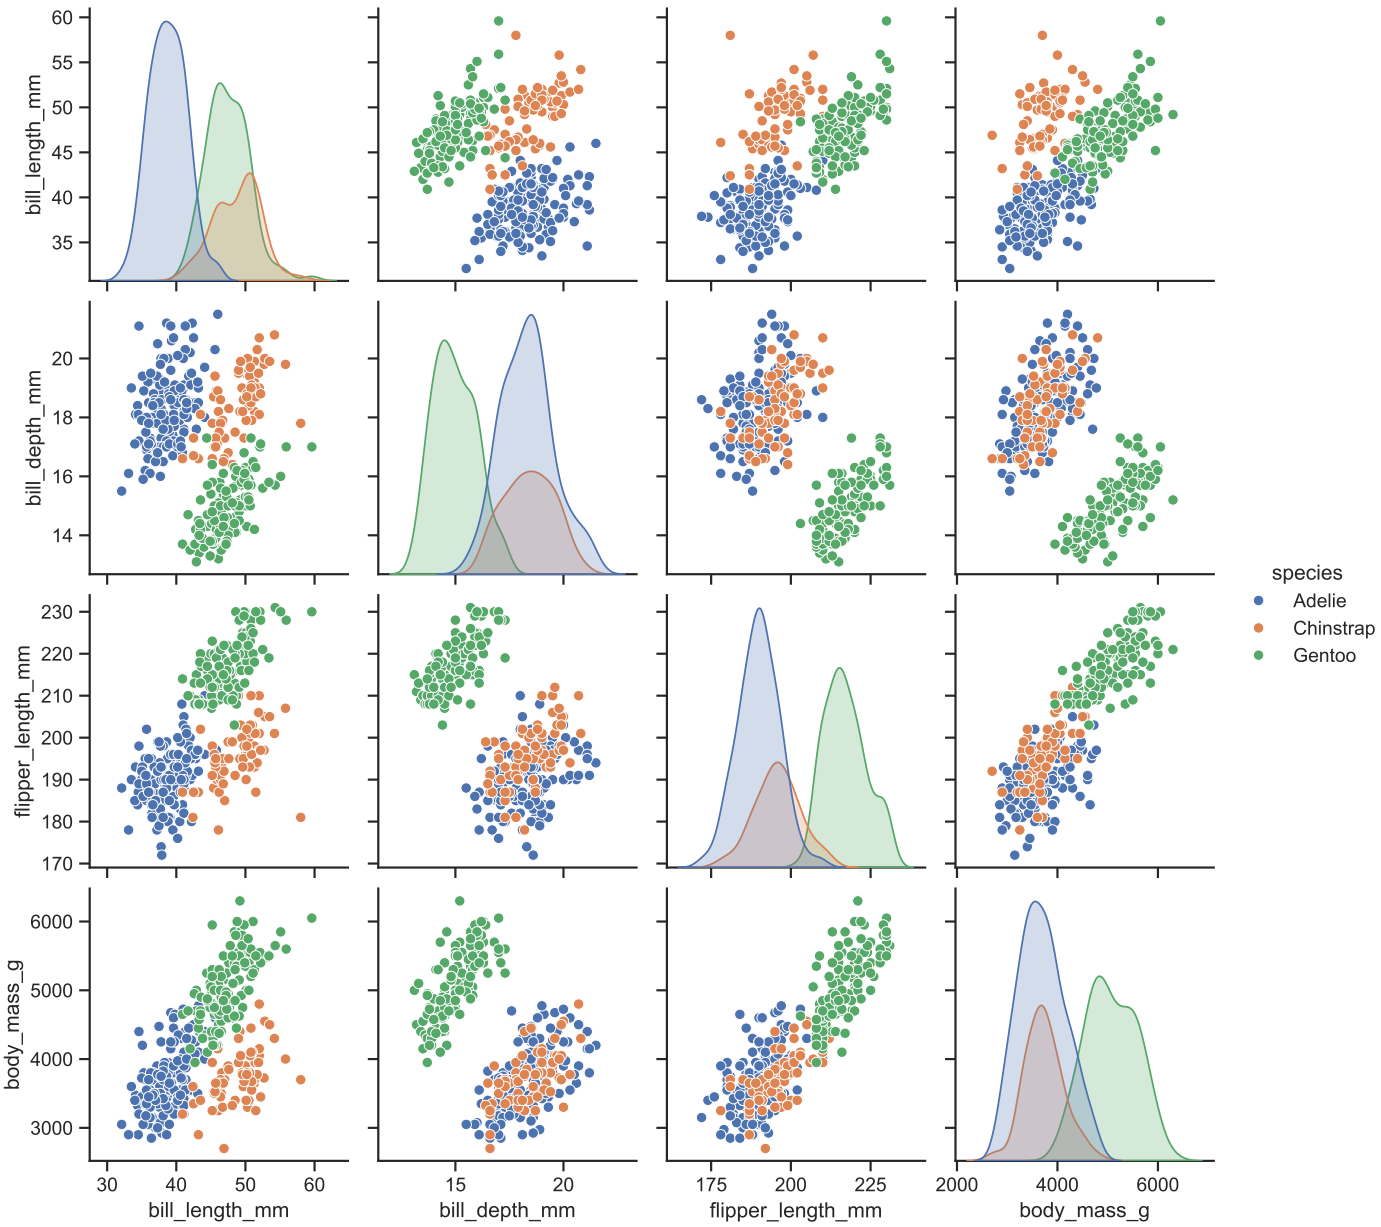
    sns.set_theme(style='ticks')
    df = sns.load_dataset('penguins')
    sns.pairplot(df, hue='species')
    fig = plt.gcf()

# Start of output choices
    if (OutputMode == 'plt'):
        plt.show()
    elif (OutputMode == 'gui'):
        gui.plot(fig, __file__, Title)
    else:
        FName = 'Temp'
        if OutputDir != 'Temp': FName = (Path(__file__).stem)
        LocalDir = gui.get_local_appdata_xlcalcnet()
        FullPath = os.sep.join([LocalDir, OutputDir, FName + '.' + OutputMode])
        plt.savefig(FullPath,  bbox_inches='tight')
        if OutputDir != 'Temp': print('Graphics written to: ', FullPath)
    plt.close('all')

try:
    if __name__ == '__main__':
        ScatterplotMatrix(OutputMode='gui')

except Exception:
    import traceback
    print(traceback.format_exc())
```

This produces the following output:



bill_length_mm
bill_depth_mm
flipper_length_mm
body_mass_g
species
Adelie
Chinstrap
Gentoo

1.1.4.6 Statsmodels

Statsmodels is a Python package for statistical computations. For more information, see https://www.statsmodels.org/stable/index.html.

Assuming that the Python batch files have been installed as described *here*, Statsmodels can be installed by double-clicking on the batch file `A09installstatsmodels.bat` in the `C:\Python313` folder.

The following example shows how Statsmodels can be used for ordinary least squares calculations:

```
import time
import numpy as np
import pandas as pd
import statsmodels.api as sm

# See also: https://www.statsmodels.org/stable/examples/notebooks/generated/ols.html

def OLS(**kwargs):

# End of standard key word arguments

    nsample = 100
    x = np.linspace(0, 10, 100)
    X = np.column_stack((x, x**2))
    beta = np.array([1, 0.1, 10])
    e = np.random.normal(size=nsample)

    X = sm.add_constant(X)
    y = np.dot(X, beta) + e

    model = sm.OLS(y, X)
    results = model.fit()
    print(results.summary())

try:
    if __name__ == '__main__':
        start0 = time.time()
        OLS()
        end0 = time.time()
        print('Elapsed time:', format(end0 - start0, '.4g'), 'seconds' )

except Exception:
    import traceback
    print(traceback.format_exc())
```

The output looks like this

```

1.1.4.7 Scikit-learn

Scikit-learn is a Python package for machine learning. For more information, see https://scikit-learn.org/stable/index.html.

Assuming that the Python batch files have been installed as described *here*, Scikit-learn can be installed by double-clicking on the batch file `A10install_scikit_learn.bat` in the `C:\Python313` folder.

The following example shows how Scikit-learn can be used for a Principal Component Analysis (PCA) on the Iris dataset.:

```
from xlcalcnet import gui
from pathlib import Path
import os, time
import numpy as np
from sklearn.decomposition import PCA

# see https://scikit-learn.org/stable/auto_examples/decomposition/plot_pca_iris.html

def PlotPCA(**kwargs):
    OutputDir = kwargs['OutputDir'] if 'OutputDir' in kwargs else 'OutputMonitor'
    Title = kwargs['Title'] if 'Title' in kwargs else 'First three principal components'
    PlotStyle = kwargs['PlotStyle'] if 'PlotStyle' in kwargs else 'default'
    OutputMode = kwargs['OutputMode'] if 'OutputMode' in kwargs else 'svg'
    FigSizeX = float(kwargs['FigSizeX']) if 'FigSizeX' in kwargs else 8
    FigSizeY = float(kwargs['FigSizeY']) if 'FigSizeY' in kwargs else 6
    Resolution = int(kwargs['Resolution']) if 'Resolution' in kwargs else 300
# End of standard key word arguments

    # Choose 'Agg' as backend unless we want to display the graphics
    if (OutputMode != 'gui'):
        import matplotlib
        matplotlib.use('Agg')
    import matplotlib.pyplot as plt
    plt.style.use(PlotStyle)

    from sklearn.datasets import load_iris
    iris = load_iris(as_frame=True)
    #print(iris.keys())
    fig = plt.figure(1, figsize=(FigSizeX, FigSizeY))
    ax = fig.add_subplot(111, projection='3d', elev=-150, azim=110)

    X_reduced = PCA(n_components=3).fit_transform(iris.data)
    scatter = ax.scatter(
        X_reduced[:, 0],
        X_reduced[:, 1],
        X_reduced[:, 2],
        c=iris.target,
        s=40,
    )
    ax.set(
        title=Title,
        xlabel='1st Principal Component',
        ylabel='2nd Principal Component',
        zlabel='3rd Principal Component',
    )
    ax.xaxis.set_ticklabels([])
    ax.yaxis.set_ticklabels([])
    ax.zaxis.set_ticklabels([])

    # Add a legend
    legend1 = ax.legend(
        scatter.legend_elements()[0],
        iris.target_names.tolist(),
        loc='upper right',
        title='Classes',
    )
    ax.add_artist(legend1)
```

(continues on next page)

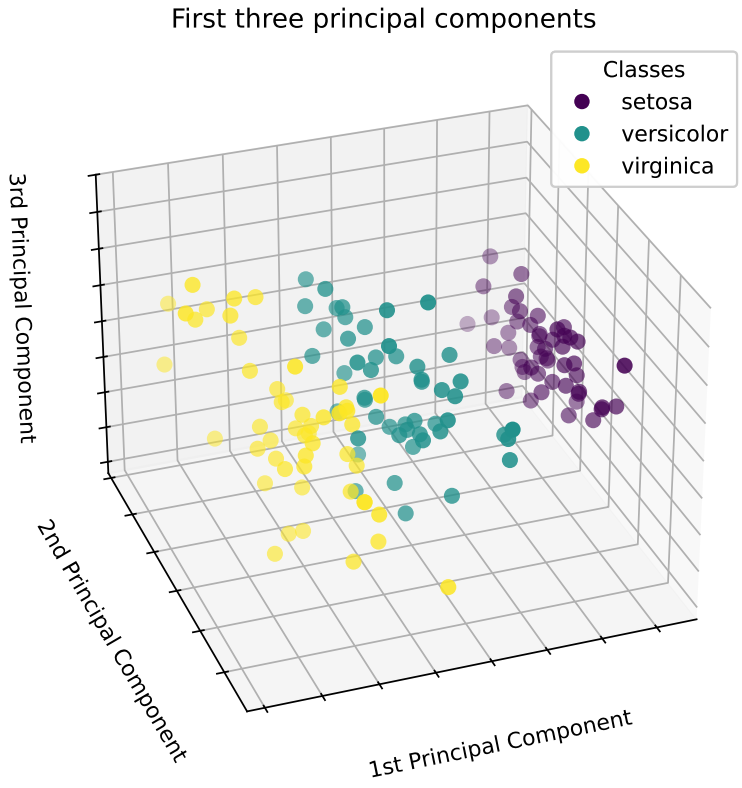
(continued from previous page)

```
# Start of output choices
    if (OutputMode == 'plt'):
        plt.show()
    elif (OutputMode == 'gui'):
        gui.plot(fig, __file__, Title)
    else:
        FName = 'Temp'
        if OutputDir != 'Temp': FName = (Path(__file__).stem)
        LocalDir = gui.get_local_appdata_xlcalcnet()
        FullPath = os.sep.join([LocalDir, OutputDir, FName + '.' + OutputMode])
        plt.savefig(FullPath,  bbox_inches='tight')
        if OutputDir != 'Temp': print('Graphics written to: ', FullPath)
    plt.close('all')

try:
    if __name__ == '__main__':
        start0 = time.time()
        PlotPCA(OutputMode = 'gui')
        end0 = time.time()
        print('Elapsed time:', format(end0 - start0, '.4g'), 'seconds' )

except Exception:
    import traceback
    print(traceback.format_exc())
```

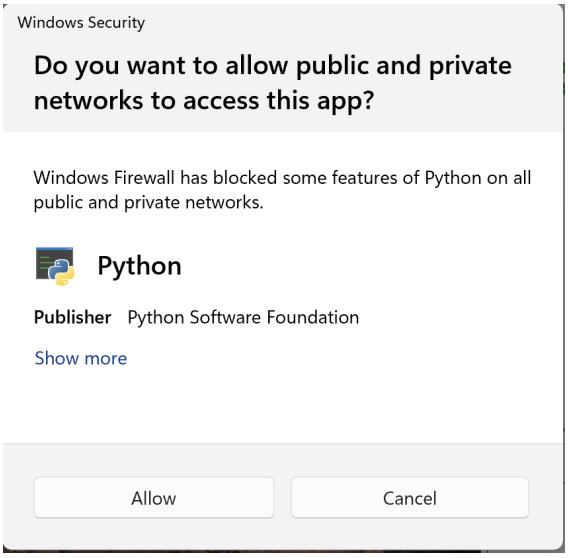
The output looks like this:



1.1.5 Calling Python from C:#: socket server vs in-process calls

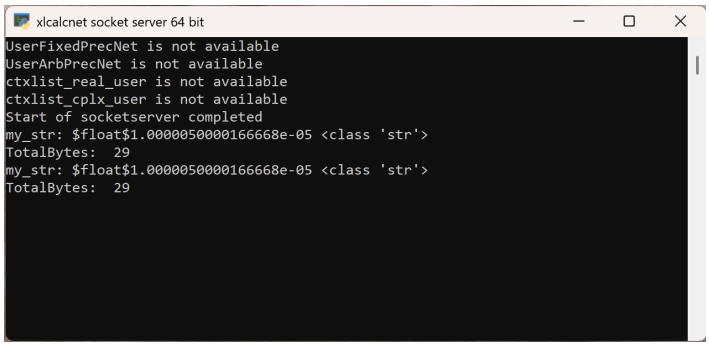
A running socket server is critical for the use of XlCalcNet from Microsoft Excel.

When starting the socket server for the first time from a specific installation of python.exe, a dialog will appear to allow access of this version of Python to networks.



Confirm, since this is required for the socket server to work properly. If you have multiple installations of Python, you may have to do this for each installation.

The socketserver is started from the TinyIDE: in the main menu, click on `Tools` -> `Start SocketServer`.



1.1.5.1 Calling the socketserver from C#

The full C# source code of the example below can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D05a_CallSocketServer.cs.

The following example illustrates the use:

```
#region Usings
using MpFunLabClient;
using System;
using System.Diagnostics;
using System.Globalization;
using System.Threading;
using System.Numerics;
using FixedPrecNet;
#endregion
```

(continues on next page)

(continued from previous page)

```
static class Program
{

public static void MainTests()
{
    Console.WriteLine("Demo of call socket server");
    for (int i = 0; i < 1; i++)
        TestSocketServer();
}

public static void TestSocketServer()
{
    Console.WriteLine("Hello TestSocketServer!");
    bool Transpose = false;
    bool ShowShape = true;

    string Code2 = "from A01_ExamplesPython.B18_FunctionsAndCurvesPlots.C02_BasicCurves import D02_Circle;";
    Code2 += "D02_Circle.CircleXY(); result = 'Done'";

    dynamic ResultFinal = MpFunLabSocketClientClass.CallSocketServer0(Code2, Transpose, ShowShape);
    Console.WriteLine();
    Console.WriteLine("Returned:");
    Console.WriteLine("{0}, {1}", ResultFinal.ToString(), ResultFinal.GetType());

    try
    {
        int U0 = ResultFinal.GetUpperBound(0);
        int U1 = ResultFinal.GetUpperBound(1);
        Console.WriteLine("U0: {0}, U1: {1}", U0, U1);
        for (int i = 0; i <= U0; i++)
        {
            for (int j = 0; j <= U1; j++)
            {
                Console.WriteLine("{0}, {1}", ResultFinal[i, j], ResultFinal[i, j].GetType());
            }
        }
    }
    catch (Exception)
    {
    }
    Console.WriteLine();
}
```

The Python source code for the socketserver itself can be found here: https://github.com/duhadler/XlCalcNet/blob/master/xlcalcnet/Addin/NET48/Bin/socketspy.py

The C# source code for the socket client which is called by the above program can be found here: https://github.com/duhadler/XlCalcNet/tree/master/xlcalcnet/Addin/NET48/Source/ClientServer

1.1.5.2 Calling Python from C# in-process

With Pythonnet, it is possible to call python from C# in-process. For the purposes of XlCalcNet this method is slower than calling the socket server. However, in other use cases, it might be the preferred method.

The full C# source code of the example below can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D05b_TestPythonNet.cs.

The following example illustrates the use. Note that this requires including a `using Python.Runtime;` statement (line 6), passing the full path of the Python root directory(line 61), the Python DLL path (line 62) and setting a number of environment variables (lines 87-90). The Python engine must be initialized before any Python code can be executed (line 22):

```
1 #region Usings
2 using System;
```

(continues on next page)

(continued from previous page)

```
using System.Collections.Generic;
using System.Numerics;
using FixedPrecNet;
using Python.Runtime;
#endregion

static class Program
{

public static void MainTests()
{
    TestPythonNet0();
}

#region TestPythonNet0

public static void TestPythonNet0()
{
    Console.WriteLine("Hello TestPythonNet1");
    PythonEngine.Initialize();
    using (Py.GIL())
    {
        dynamic np = Py.Import("numpy");
        Console.WriteLine(np.cos(np.pi * 2));

        dynamic sin = np.sin;
        Console.WriteLine(sin(5));

        double c = (double)(np.cos(5) + sin(5));
        Console.WriteLine(c);

        dynamic a = np.array(new List<float> { 1, 2, 3 });
        Console.WriteLine(a.dtype);

        dynamic b = np.array(new List<float> { 6, 5, 4 }, dtype: np.int32);
        Console.WriteLine(b.dtype);

        Console.WriteLine(a * b);
    }
}

#endregion

/* This region contains the program entry point. Do not change */
#region Main

public static void Main(string[] args)
{
    if (args.Length < 2)
    {
        Console.WriteLine(
            "This application needs to be started with 2 arguments;");
        Console.WriteLine("See the manual of xlcalcnet for details.");
    }
    else

            Environment.SetEnvironmentVariable("PYTHONNET_PYDLL",
                _PythonNetPyDll);
            MainTests();
        }
        catch (Exception Ex)
        {
            Console.Error.WriteLine(Ex.Message);
            Console.Error.WriteLine("$+$");
            Console.Error.WriteLine(Ex.StackTrace);
            Console.Error.WriteLine("$+$");
        }
        stopWatch.Stop();
        var ts = stopWatch.Elapsed;
        string elapsedTime = string.Format("{0:00}:{1:00}:{2:00}.{3:00}",
            ts.Hours, ts.Minutes, ts.Seconds, ts.Milliseconds / 10);
        Console.WriteLine("<H1 Title=" + "\"" + "General Info" + "\"" + ">");
        Console.WriteLine("Elapsed Time " + elapsedTime);
        Console.WriteLine("------------------------------------------------");
        Console.WriteLine("Memory used before collection:       {0:N0}",
            GC.GetTotalMemory(false));
        GC.Collect();
        Console.WriteLine("Memory used after full collection:   {0:N0}",
            GC.GetTotalMemory(true));
        Console.WriteLine("------------------------------------------------");
        Console.WriteLine("");
        Console.WriteLine("</H1>");
    }

}

private static string _PythonRootDir;
private static string _PythonNetPyDll;
private static string _LocalAppDataDir;

/*
    The code for LoadFromXlCalcNet, LoadFromXlCalcNet2, LoadFromPythonNet
    and LoadFromAppLocal is not shown here
*/

#endregion

}
```

Running the program produces the following output:

```
Hello TestPythonNet1
1.0
-0.9589242746631385
-0.675262089199912
float64
int32
[ 6. 10. 12.]
<H1 Title="General Info">
Elapsed Time 00:00:00.58
-------------------------------------------------
Memory used before collection:       5,854,328
Memory used after full collection:   1,431,368
-------------------------------------------------

</H1>
```

In other words, it took about 0.58 seconds to run the program. This is much slower than calling the socket server, which takes about 0.02 seconds. The reason for this is that Pythonnet has to load the entire Python interpreter into the C# process, which takes a lot of time and memory. In contrast, the socket server runs in a separate process and can be started once and then used for multiple calls from C#.

1.1.6 Reasons for using multiprecision arithmetic

An introduction to the problems of rounding errors and catastrophic cancellation can be found in Goldberg [351]. Excellent reference texts are Higham [370] and Higham [371].

In the following sections we will give a few examples of how the use of double precision without special precaution can give wrong results.

Example: Sums

Sums are often calculated exactly if all summands have an exact representation. If this is not the case, results can be unpredictable. In MS Excel, the formula

```
=SUM(10000000000,-16000000000,6000000000)
```

will give the correct result 0, but the analogous formula

```
=SUM(1E+40,-1.6E+40,6E+39)
```

returns $1.20893E+24$ instead of the correct result 0.

Example: Standard Deviation

Like sums, variances and standard deviations are often calculated exactly if all arguments have an exact representation. If this is not the case, results can again be unpredictable. In MS Excel, the formula

```
=VAR(1E+30,1E+30,1E+30)
```

returns $2.97106E+28$ instead of the correct result 0, which should be the obvious results since all arguments are the same.

Example: Overflow and underflow

In many situations where the final result is representable in double precision, some of the interim results cause overflow or underflow. A popular example is the function $f(x,y) = \sqrt{x^2+y^2}$. With $x = 3 \cdot 10^{300}$ and $y = 4 \cdot 10^{300}$ the result $f(x,y) = 5 \cdot 10^{300}$ is representable in double precision, but the (naive) calculation will overflow.

Example: Polynomials

Consider the following example from Cuyt *et al.* [190]:

For $a = 77617$ and $b = 33096$, calculate

$$Y = 333.75b^6 + a^2(11a^2b^2 - b^6 - 121b^4 - 2) + 5.5b^8 + \frac{a}{2b}$$

The correct result is $Y = -54767/66192 = -8.27396\ldots \cdot 10^{-1}$

Example: Trigonometric Functions

Trigonometric functions are sensitive to small perturbations.

In double precision and binary floating point arithmetic, the tangent of $x = 1.57079632679489$ is calculated as $\tan(x) = 1.48752 \cdot 10^{14}$, whereas the correct result is $\tan(x) = 1.51075 \cdot 10^{14}$. This amounts to an absolute error of $2.32287 \cdot 10^{12}$ and a relative error of 1.54%.

There are also limits on the range of arguments, e.g. $\sin(10^8)$ returns the value $-9.31639 \cdot 10^{-1}$ (with an relative error of $-6.22776 \cdot 10^{-13}$), whereas $\sin(10^9)$ returns an invalid result (the exact result is $5.45843 \cdot 10^{-1}$)

Example: Logarithms and Exponential Functions

Consider the following example from Kaveh R. Ghazi and Vincent Lefèvre and Philippe Théveny and Paul Zimmermann [1505]:

Determine 10 decimal digits of the constant

$$Y = 173746a + 94228b - 78487c, \quad \text{where}$$

$$a = \sin(10^{22}), b = \log(17.1), c = \exp(0.42).$$

The expected result is $Y = -1.341818958 \cdot 10^{-12}$.

Example: Linear Algebra

The following example is from W. Hofschuster and W. Krämer [1506]:

We want to solve the (ill-conditioned) system of linear equations $Ax = b$ with

$$A = \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix} = \begin{pmatrix} 64919121 & -159018721 \\ 41869520.5 & -102558961 \end{pmatrix}, b = \begin{pmatrix} b_1 \\ b_2 \end{pmatrix} = \begin{pmatrix} 1 \\ 0 \end{pmatrix}, x = \begin{pmatrix} x_1 \\ x_2 \end{pmatrix}$$

The correct solution is $x_1 = 205117922$, $x_2 = 83739041$.

To solve this 2×2 system numerically we first use the well known formulas

$$x_1 = \frac{a_{22}}{a_{11}a_{22} - a_{12}a_{21}}, \quad x_2 = \frac{-a_{21}}{a_{11}a_{22} - a_{12}a_{21}},$$

Calculating this directly in double precision gives the following wrong result:

$x_1 = 102558961$, $x_2 = 41869520.5$

Example: Eigenvalues

The following example is from Brown *et al.* [161]:

The behaviour and stability of many physical systems are connected with the spectral properties of non-self-adjoint operators. However, numerical approximations of eigenvalues of non-selfadjoint operators (even matrices) may fail dramatically. For example, the non-normal 7×7 matrix

$$A = \begin{pmatrix} 289 & 2054 & 326 & 128 & 70 & 32 & 6 \\ 1152 & 30 & 1312 & 512 & 288 & 128 & 32 \\ -29 & -1990 & 766 & 384 & 1018 & 224 & 58 \\ 512 & 128 & 640 & 0 & 640 & 512 & 128 \\ 1053 & 2246 & -514 & -384 & -766 & 800 & 198 \\ -287 & -6 & 1722 & -128 & 1978 & -30 & -2042 \\ -2176 & -285 & -1563 & -512 & -539 & -1152 & -287 \end{pmatrix}$$

has the eigenvalues $-2, -4, 0, 1, 1, 2, 4$. Calculations in double precision yield a set of complex eigenvalues, such as $8.57 \pm 3.73i; 2.29 \pm 8.33i; -5.43 \pm 6.56i; -8.85$ with imaginary parts as large as 8.33, which are nowhere near the true eigenvalues. The reason for this is that owing to the nonnormality of the matrix, its eigenvalues are highly sensitive to perturbations, and therefore unavoidable rounding errors render the numerical eigenvalue computations unreliable.

1.1.7 Rebuilding the .dll files of XlCalcNet and XlCalcNet2 from source code

The XlCalcNet and XlCalcNet2 python packages contain both precompiled .dll files and their source code.

This section descibes how to rebuild the .dll files of XlCalcNet and XlCalcNet2 from source code, either completely or only in part. The building process itself is not particularly difficult, but it requires the installation of MSYS2 (version 3.4.9.x86_64 or later: about 4 GB in size), Free Pascal (version 2.6.4 or later: about 320 MB in size), and Visual Studio Community (version 2019 or later: about 4.6 GB in size).

In the following it is assumed that the user has installed MSYS2, Free Pascal and Visual Studio Community and is comfortable using them.

MSYS2 is required to build the file `FixedPrecGCC64K8.dll` in the XlCalcNet `Bin` folder. The details of the building process are described in *FixedPrec*.

MSYS2 is also required to build the file `ArbPrecNetGCCK8.dll` in the XlCalcNet2 `Bin` folder. The details of the building process are described in *ArbPrec*.

Free Pascal is required to build the file `libwe64d.dll` in the XlCalcNet `Bin` folder. The details of the building process are described in *FixedPrec*.

Erverything else can be done in Visual Studio Community:

The details of building the file `FixedPrecNet.dll` in the XlCalcNet `Bin` folder are described in *FixedPrec*.

The details of building the file `ArbPrecNet.dll` in the XlCalcNet2 `Bin` folder are described in *ArbPrec*.

The details of building the files `MpFunLabClient.dll` and `MpFunLabAddin64.dll` in the XlCalcNet `Bin` folder are described in *ClientServer*.

The details of building the file `TinyOutputMonitorUserCtrl.dll` in the XlCalcNet `Bin` folder are described in *OutputMonitor*.

The details of building the file `TinyIDEUserCtrl.dll` and `FindReplaceSD.dll` in the XlCalcNet `Bin` folder are described in *TinyIde*.

The details of building the file `TinyPlot2DUserCtrl.dll` in the XlCalcNet `Bin` folder are described in *GalleryOfPlots*.

The details of building the file `TinyPlot3DUserCtrl.dll` in the XlCalcNet `Bin` folder are described in *Wpf3D*.

The details of building the file `TinyDataViewerUserCtrl.dll` in the XlCalcNet `Bin` folder are described in *DataViewer*.

All other .dll files in the XlCalcNet `Bin` folder have been aquired via https://www.nuget.org/ from the supporting libraries and should probably not be changed.

1.2 Using XlCalcNet within MS Excel

Compared to Microsofts "Python in Excel" (see https://support.microsoft.com/en-us/excel/python/introduction-to-python-in-excel), the following features of XlCalcNet can be highlighted:

- Everything is open source and can be modified by the user.
- The user can use any (locally installed) Python version from 3.8 to 3.15, and any Python package, including packages which are not supported by Microsoft.
- MS Excel 2010 - 2024 are supported.
- Everything stays local. No data and no code leave the computer of the user. An internet connection is not necessary.
- Using Python.NET, code written in C# can also be used from Python, and therefore from MS Excel.
- The user can use any Python IDE, including the Tiny IDE which is part of XlCalcNet.
- The user can write functions of arbitrary length and complexity in Python using an external editor, and call them in a short Python script in a spreadsheet cell.
- Such functions can also be called as procedures from VBA.
- There is extensive support for calculations in multiprecision, including arbitrary precision.

1.2.1 Preparing MS Excel for using XlCalcNet

Important

Before beginning to install the MS Excel addins, make sure that the socket server is up and running as expected (see the section above). When calling a function, which calls the socket server, for the first time, MS Excel will seem to freeze if the socket server does not respond quickly. However, subsequent calls will return quickly when the socket server is not up and running (there seems to be a learning effect).

To enable the use of XlCalcNet in MS Excel, two add-ins need to be installed: the first, named `Mpfunlablocal.xlam`, contains functions written in Visual Basic for Applications (VBA), including functions populating the XlCalcNet Navigator dialog, and is intended to be modified by the user during normal use. This add-in is located in a subfolder of the `DataXlCalcNet` folder in the `Documents` folder: `DataXlCalcNet\SpreadsheetAddins\MSExcel`.

The second, named `Mpfunlab.xll`, contains the functionality behind the spreadsheet functions `CPY_0` - `CPY_9` and `ASDOUBLE` and the XlCalcNet Navigator dialog container. The files comprising the whole add-in (`Mpfunlab.xll`, `ExcelDna.Integration.dll`, `MpFunLabAddin64.dll`, `MpFunLabClient.dll`, `MpFunLab.Dna`) have been compiled using Visual Studio and are NOT intended to be modified by the user during normal use. This add-in is located in the `Bin` folder in the `XlCalcNet` package: `PathToPython\Lib\site-packages\xlcalcnet\Addin\NET48\Bin`, where `PathToPython` is the path to the Python installation (in our example `C:\Python313`).

1.2.1.1 Installing Mpfunlablocal.xlam and Mpfunlab.xll

To install these two add-ins properly, follow these steps:

Again, make sure that the socket server is up and running.

Within MS Excel, on an Excel worksheet, open the Add-ins dialog from the main menu/ribbon: `Developer` -> `Excel Add-ins`. In the Add-ins dialog, click on `Browse...` and in the `Documents` folder navigate to the folder `DataXlCalcNet\SpreadsheetAddins\MSExcel`. Double-click on `Mpfunlablocal.xlam`, which will then appear in the Add-ins dialog under "Add-ins available". Still in the Add-ins dialog, click on `Browse...` again, and navigate to the folder `PathToPython\Lib\site-packages\xlcalcnet\Addin\NET48\Bin` (see above). Double-click on `Mpfunlab.xll`, which will then appear in the Add-ins dialog under "Add-ins available". Still in the Add-ins dialog, click on `OK`. Exit MS Excel.

When starting MS Excel the next time, both add-ins will be loaded.

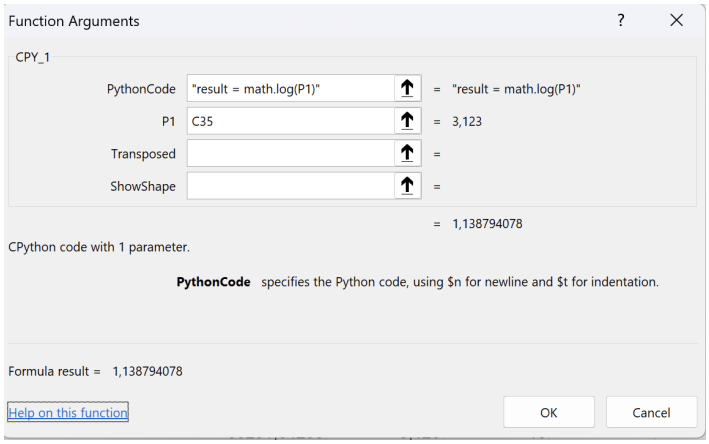
1.2.2 Using the Python standard library functions within spreadsheet formulas

> **Note**
>
> In the following subsections, we will work with the file `XlDemoCPYstd.xlsx`, which contains examples for using the Python standard library. More advanced examples using Numpy, Matplotlib, Pandas, Scipy, Seaborn and XlCalcNet start *here*, and examples for using dynamic arrays in MS Excel with XlCalcNet start *here*.

Within MS Excel, open from the main menu `File -> Open` in the Documents folder the MS Excel workbook `DataXlCalcNet\DataExamples\MainExamples\Workbooks\XlDemoCPYstd.xlsx`.

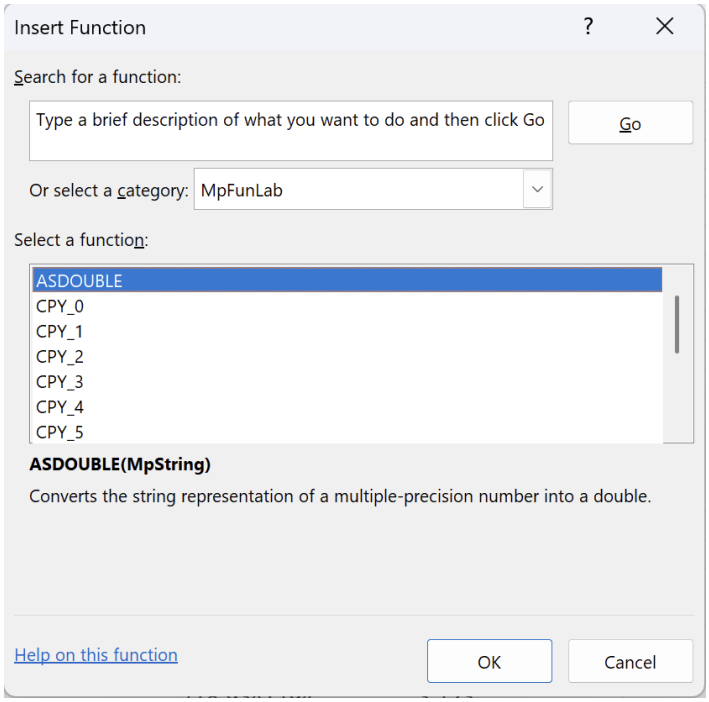
This file contains several worksheets which demonstrate different possibilities of using the Python standard library within MS Excel spreadsheet formulas.

Before we start with that we will briefly explore the use of these functions with the Function Dialog of MS Excel: In the worksheet "Math", select cell `B12` and click on the icon of the Function Dialog in the Formula Bar. This opens the Function Dialog:



We see that the formula in the spreadsheeet cell is `=CPY_1("result = math.ceil(P1)",C12)`. The function `CPY_1` has a required string parameter, `Formula`, which contains a Python script. This python script can contain several Python statement. The last statement is always expected to assign a value to the variable result, in this case a Python float, which is coverted to a floating point number in double precision (a "Double") in LibreOffice. The next optional parameter, `Param1`, can be a string, a Double, a Boolean value or a reference. In this case, it is a reference (`C12`) which points to a Double with the value `3.123`. This optional parameter, `Param1`, is referenced in the Python formula given above as `P1`. The last but one parameter, `Transposed`, and the last parameter, `ShowShape`, are only relevant when arrays are returned; this is discussed *here*.

In the worksheet "Math", select an emptz cell and click on the icon of the Function Dialog in the Formula Bar. This opens the Function Insert Dialog:



We see that the function `CPY_1` is in the Category "MpFunLab", and that there are 10 functions, `CPY_0` to `CPY_9`, which differ only by the number of parameters `Param1` to `Param9` which they support (The function `CPY_0` does not have a parameter `Param0`). There is also a function `ASDOUBLE`, which is used to convert string representations of a Python Fraction or Decimal into a Double; this is discussed *here*.

1.2.2.1 The worksheet "GeneralInfo"

The worksheet "GeneralInfo" contains calls to the Python modules `os`, `platform` and `sys`.

For example, the cell `B4` contains the formula `=CPY_0("result = platform.processor()")`. The function result depends on the hardware, e.g. `Intel64 Family 6 Model 165 Stepping 5, GenuineIntel`.

The cell `B16` contains the formula `=CPY_0("result = os.getcwd()")`. The function result depends on the LibreOffice installation, e.g. `C:\Program Files\LibreOffice\program`.

The cell `B33` contains the formula `=CPY_0("result = str(sys.float_info.epsilon)")`, which return the machine epsilon in double precision. The function result is: `2.220446049250313e-16`.

1.2.2.2 The worksheet "Math"

The worksheet "Math" demonstrates the use of the Python module `math` and the use of parameters in functions.

For example, the cell `B33` contains the formula `=CPY_1("result = math.exp(P1)-1",C33)`, which calculates $\exp(\mathrm{P1})-1$ naively. The function result is `1.00000500000696E-05`, with the cell `C33` containing the value `0.00001`.

The cell `B34` contains the formula `=CPY_1("result = math.expm1(P1)",C34)`, which calculates $\exp(\mathrm{P1}) - 1$ using the `expm1` function. The function result is `1.00000500001667E-05`, with the cell `C34` again containing the value `0.00001`.

The floating point values `NaN`, `+inf` and `-inf` are not supported in spreadsheet programs, which only return `#NUM!` in these cases. Use the string representation instead. This is shown in the cells `A4:B9` on this worksheet.

The cell `B36` contains the formula `=CPY_2("result = math.log(P1, P2)",C36, D36)`, with the cell `C36` containing the value `3.123` and the cell `D36` containing the value `10`. The function result is: `0.494571984230199`.

1.2.2.3 The worksheet "Arrays"

The worksheet "Arrays" demonstrates the use of arrays in functions. The Python equivalent of arrays are lists.

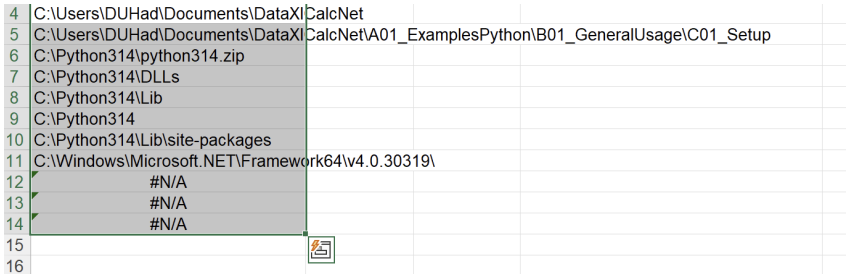
For example, the cell `B3` contains the formula `=CPY_0("result = str(sys.path)")`. The function `sys.path` returns a list of strings (containing the entries of the Python path), which is converted into one string by writing `str(sys.path)`. This makes sure that the result can be displayed in one cell, but the result string is quite long and hard to read.

We can use an array formula to improve readability. We recall that in addition to the usual parameters `P1` - `P9` in the functions `CPY_0` to `CPY_9` there are two more: The last but one paramter, named `Transposed`, which is optional with default value 0, where a non-zero value means that the returned array should be transposed; and the last paramter, named `ShowShape`, which is optional with default value 0, where a non-zero value means that the shape of the returned array should be indicated like `R7C3` for an array with 7 rows and 3 columns.

As an example, the cell `B6` contains the formula `=CPY_0("result = sys.path",1,1)` and returns the shape information `R12C1` followed by the separator `|`, followed by the first entry of the transposed array, i.e. in this case `R12xC1| C:\Users\DUHad\Documents\DataXlCalcNet`.

We can build the corresponding array formula by first selecting a range like `R12C1`, then typing in the input line of the formula bar `=CPY_0("result = sys.path",1,0)`, and finally, while keeping the shift and control keys pressed down, pressing the enter key.

This is what has been done in cells `B9:B20`. The formula is now displayed as `{=CPY_0("result = sys.path",1,0)}`, with curly braces, to indicate that it is an array formula. We can change the range which is covered by the array formula by dragging the small blue rectangle in the lower right corner in the selected range (see the screenshot below).



1.2.2.4 The worksheet "Data"

The worksheet "Data " demonstrates the use of named ranges in MS Excel spreadsheet formulas.

Currently there a two small datasets with predefined as named ranges: `matA` defined as the range $Data.$A$3:$A$7 and `matB` defined as the range $Data.$A$3:$A$7.

These ranges are used in the workbook "Arrays".

1.2.3 Using Numpy, Matplotlib, Pandas, Scipy, Seaborn and XlCalcNet within spreadsheet formulas

> **Note**
>
> In the following subsections we will work with the file `XlDemoCPYadv.xlsx`, which contains more advanced examples using Numpy, Matplotlib, Pandas, Scipy, Seaborn and XlCalcNet. Examples for using MS Excel with the Python standard library start *here*, and an example of using dynamic arrays in MS Excel starts *here*.

Within MS Excel, open from the main menu `File -> Open` in the Documents folder the MS Excel workbook `DataXlCalcNet\DataExamples\MainExamples\Workbooks\XlDemoCPYadv.xlsx`.

This file contains several worksheets which demonstrate different possibilities of using Numpy, Matplotlib, Pandas, Scipy, Seaborn and XlCalcNet within MS Excel spreadsheet formulas.

Some of these functions write their output into the `XlCalcNetIDE\OutputMonitor` folder in the AppDataLocal folder. In order to see it, we need to open the `Output Monitor` application: start the `Tiny IDE` by clicking on its icon in the task bar, and in the main menu, click on `Tools` -> `Start Output Monitor`.

1.2.3.1 The worksheet "FractionsInput"

The worksheet "FractionsInput " demonstrates the use of the Python data type `Fraction` in MS Excel spreadsheet formulas.

MpInputFractions | 123456789012345678 / 901234567890

If we try to enter a number like `123456789012345678/901234567890`, i.e. a number with more than 16 digits into a spreadsheet cell, it will automatically be shortened to `1.23456789012346E+029`. In order to be able to enter such numbers into spreadsheet cells, the cells must first be formatted as text, and thereafter these numbers can be entered as text. This is mostly useful when working with Python Fractions and Decimals.

However, this kind of input is hard to read; it is also not directly usable for numerical spreadsheet functions. This can be changed by using the function `ASDOUBLE`, a shown in column `B`

As an example, worksheet "FractionsInput" contains a named range called "MpInputFractions" in column `A`, which can be used as input for descriptive statistics or linear algebra routines.

The module `npm` of XlCalcNet can be used to calculate desciptive statistics, like `prod`, `sum`, `mean`, `median`, `variance` with fractions. The function `npm.mean` can be called from a spreadsheet cell as follows:

```
=CPY_1("from xlcalcnet import npm, qpm $n x = npm.array(P1, dtype=qpm); result=str(npm.prod(x))",MpInputFractions)
```

Às before, we are using `$n` for newline and `$t` for indentation. The result is itself a `Fraction` (converted to a string), and is exact. The corresponding Python code with conventional formatting would look like this (where `P1` is the input range):

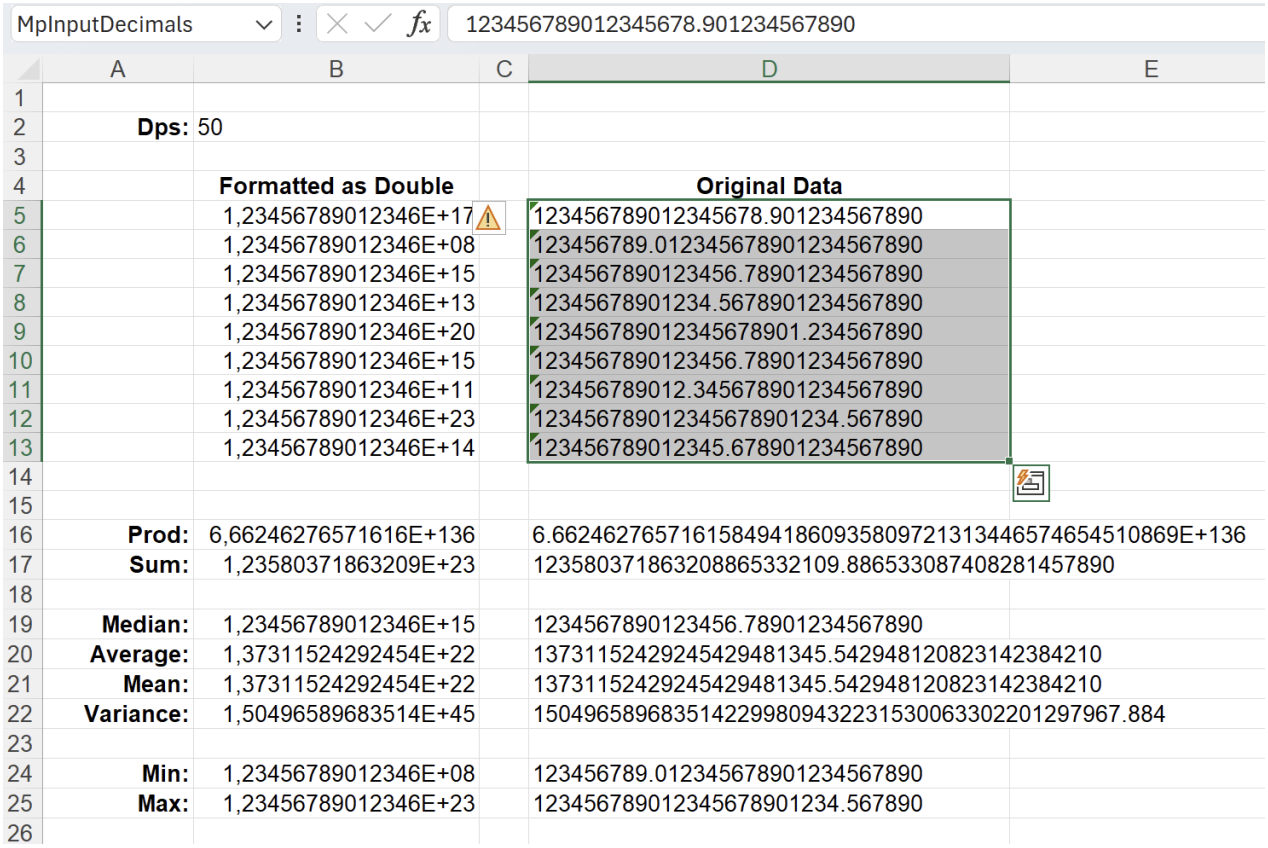
```
from xlcalcnet import npm, qpm
x = npm.array(P1, dtype=qpm)
result=str(npm.prod(x))
```

Note that the input range is converted into a Numpy array with data type `qpm`, which is the data type for rational numbers in XlCalcNet. The result is then converted into a string, so that it can be displayed in a spreadsheet cell.

Since the string output is quite long, we can use `result=float(npm.prod(x))` instead of `result=str(npm.prod(x))` to get a floating point number in double precision, which is more readable. However, this will not be exact anymore.

1.2.3.2 The worksheet "DecimalsInput"

The worksheet "DecimalsInput " demonstrates the use of the Python data type `Decimal` in MS Excel spreadsheet formulas.



MpInputDecimals | 123456789012345678.901234567890

20	**Average:**	1,37311524292454E+22		13731152429245429481345.542948120823142384210	
21	**Mean:**	1,37311524292454E+22		13731152429245429481345.542948120823142384210	
22	**Variance:**	1,50496589683514E+45		150496589683514229980943223153006330220129796 7.884	
23					
24	**Min:**	1,23456789012346E+08		123456789.012345678901234567890	
25	**Max:**	1,23456789012346E+23		123456789012345678901234.567890	
26					

If we try to enter a number like `123456789012345678.901234567890`, i.e. a number with more than 16 digits into a spreadsheet cell, it will automatically be shortened to `1.23456789012346E+017`. In order to be able to enter such numbers into spreadsheet cells, the cells must first be formatted as text, and thereafter these numbers can be entered as text. This is mostly useful when working with Python Fractions and Decimals.

However, this kind of input is hard to read; it is also not directly usable for numerical spreadsheet functions. This can be changed by using the function `ASDOUBLE`, a shown in column `B`

As an example, worksheet "DecimalsInput" contains a named range called "MpInputDecimals" in column `C`, which can be used as input for descriptive statistics or linear algebra routines.

The module `npm` of XlCalcNet can be used to calculate desciptive statistics, like `prod`, `sum`, `mean`, `median`, `variance` with decimals. The function `npm.mean` can be called from a spreadsheet cell as follows:

```
=CPY_2("from xlcalcnet import npm, dpm $n dpm.dps=int(P2); x = npm.array(P1, dtype=dpm); result=str(npm.mean(x))",
↪MpInputDecimals, $B$2)
```

Às before, we are using `$n` for newline and `$t` for indentation. The result is itself a `Decimal` (converted to a string), and is correct to the number of digits specified. The corresponding Python code with conventional formatting would look like this (where `P1` is the input range and `P2` is the number of digits):

```
from xlcalcnet import npm, dpm
dpm.dps=int(P2)
x = npm.array(P1, dtype=dpm)
result=str(npm.mean(x))
```

Note that the input range is converted into a Numpy array with data type `dpm`, which is the data type for decimal numbers in XlCalcNet. The result is then converted into a string, so that it can be displayed in a spreadsheet cell.

Since the string output is quite long, we can use `result=float(npm.prod(x))` instead of `result=str(npm.prod(x))` to get a floating point number in double precision, which is more readable. However, this will then be correct only to the precision of a double-precision floating-point number.

1.2.3.3 The worksheet "Programming"

The worksheet "Programming" demonstrates the use of small python scripts in MS Excel spreadsheet formulas.

	A	B	C	D
1				
2				
3	**Python standard library: simple loop**			
4	**n:**	45		
5	**Result:**	1980		
6				
7				
8				
9				
10	**Scipy: Numerical quadrature; f(x) = a*x**2 + b**			
11	**Lower limit of integration:**	-1,4		
12	**Upper limit of integration:**	1,5		
13	**Parameter a:**	2,1		
14	**Parameter b:**	1,1		
15	**Result (integral, error estimate):**	(7.473300000000001, 8.297029729931183e-14)		
16				
17				

The first example in this worksheeet shows how to program a simple loop. The formula in the cell `B4`. is

```
=CPY_1("temp = 0 $n for i in range(int(P1)): $n$t temp += i $n result = 2 * temp", B4)
```

The cell `B4` contains the value `45`; the result is `1980`. The corresponding Python code with conventional formatting would look like this(where `P1` is `n`, the number of iterations):

```
temp = 0
for i in range(int(P1)):
    temp += i
result = 2 * temp
```

The second example in this worksheet shows how to perform numerical integration.The formula in the cell `B15`. is

```
=CPY_4("from scipy.integrate import quad $n def integrand(x, a, b): return a*x**2 + b $n a = float(P3); b = float(P4);  $n I␣
↪= quad(integrand, float(P1), float(P2), args=(a,b))  $n result = str(I) ", B11, B12, B13, B14)
```

This formula calls the function `quad` from the module `scipy.integrate` in the package `scipy`. The parameters of this function are taken from the cells `B11` to `B14`. The result is a tuple containing the intergral and an error estimate. The corresponding Python code with conventional formatting would look like this (with P1 is the lower limit of integration, P2 is the upper limit, P3 is the coefficient of x^2, and P4 is the constant term):

```
from scipy.integrate import quad
def integrand(x, a, b): return a*x**2 + b
a = float(P3); b = float(P4)
I = quad(integrand, float(P1), float(P2), args=(a,b))
result = str(I)
```

The cells B16 to B17 show the same result as an array formula, with B16 containing the integral and B17 the error estimate.

1.2.3.4 The worksheet "OutputMonitorCSV"

This is a snapshot of the worksheet "OutputMonitorCSV" with the relevant formula in cell B1. The output of the formula in cell B1 is a CSV file named TTest1External.csv which is written to the Output Monitor folder. The Output Monitor application must be running in order to see the output. The Output Monitor can be started from the main menu of the Tiny IDE by clicking on Tools -> Start Output Monitor.

	A	B	C	D	E	F	G	H
1	**Python Script:**	Students t-test, 1 sample						
2								
3	**n:**	[10, 20, 30]						
4	**mu0:**	1.0						
5	**mean:**	[4.5,4.7]						
6	**std:**	[1,2,3,4]						
7	**alpha:**	0.05						
8	**Options:**	,I=True, D=True, T=True, C=True, Onesided=True, Twosided = True, OutputMode='csv'						
9								
10								
11								
12	**Note:**	The result is written to the Output Monitor folder (start the Output Monitor application first!)						
13								

The formula in the cell B1. is

```
=CPY_0(TEXTJOIN(" ",1,"from A06_UserlibExamplesPython.B29_InferentialStatistics.C01_BasicTests1Sample import D01_StudentT_
↪PValues $n importlib.reload(D01_StudentT_PValues) $n D01_StudentT_PValues.stats_student_t_1sample_test(n=",B3,", mu0=",B4,
↪", mean=",B5,", std=",B6,", alpha=", B7, B8, ")"," $n result='Students t-test, 1 sample'"))
```

This formula calls the function stats_student_t_1sample_test from the module D01_StudentT_PValues in the package A06_UserlibExamplesPython.B29_InferentialStatistics.C01_BasicTests1Sample. The parameters of this function are taken from the cells B3 to B8. The result is a CSV file named TTest1External.csv which is written to the Output Monitor folder. The corresponding Python code with conventional formatting and substitution of the referenced cell values would look like this:

```
from A06_UserlibExamplesPython.B29_InferentialStatistics.C01_BasicTests1Sample import D01_StudentT_PValues
importlib.reload(D01_StudentT_PValues)
D01_StudentT_PValues.stats_student_t_1sample_test(n=[10, 20, 30], mu0=1.0, mean=[4.5,4.7], std=[1,2,3,14], alpha=0.015,␣
↪I=True, D=True, T=True, C=True, Onesided=True, Twosided=True, OutputMode='csv')
result='Students t-test, 1 sample'
```

Note

Here we are using importlib.reload to make sure that any changes in the code of the module D01_StudentT_PValues which may have occured since the last use of this spreadsheet function become effective without restarting the Python interpreter.

The cell A3 contains ="n:", and the cell B3 contains ="[10, 20, 30]". This passes the list [10, 20, 30] as the parameter n to the function stats_student_t_1sample_test.

The cell A4 contains ="mu0:", and the cell B4 contains ="1.0". This passes the value 1.0 as the parameter mu0 to the function stats_student_t_1sample_test.

The cell A5 contains ="mean:", and the cell B5 contains ="[4.5,4.7]". This passes the list [4.5,4.7] as the parameter mean to the function stats_student_t_1sample_test.

The cell A6 contains ="std:", and the cell B6 contains ="[1,2,3,14]". This passes the list [1,2,3,14] as the parameter std to the function stats_student_t_1sample_test.

The cell A7 contains ="alpha:", and the cell B7 contains ="0.015". This passes the value 0.015 as the parameter alpha to the function stats_student_t_1sample_test.

The cell A8 contains ="Options:", and the cell B8 contains =",I=True, D=True, T=True, C=True, Onesided=True, Twosided = True, OutputMode='csv'". This passes the options I=True, D=True, T=True, C=True, Onesided=True, Twosided = True, OutputMode='csv' as keyword arguments to the function stats_student_t_1sample_test.

And this is the Output Monitor showing the result (with the project panel hidden)

1.2.3.5 The worksheet "OutputMonitorSVG"

This is a snapshot of the worksheet "OutputMonitorSVG" with the relevant formula in cell B1. The output of the formula in cell B1 is a SVG file named D07_DistPlotContinuous.svg which is written to the Output Monitor folder. The Output Monitor application must be running in order to see the output. The Output Monitor can be started from the main menu of the Tiny IDE by clicking on Tools -> Start Output Monitor.

	A	B	C	D	E	F	G	H	I
1	**Python Script:**	Beta distribution							
2									
3	**target:**	'pdf'	# 'pdf', 'cdf', 'sf', 'hf', 'chf', 'qtf', 'isf'						
4	**a:**	[5, 10.0, 20.5]							
5	**b:**	[20.5, 10.0, 5]							
6	**Title:**	'Beta distribution'							
7									
8									
9									
10	**Note:**	The result is written to the Output Monitor folder (start the Output Monitor application first!)							
11									

The formula in the cell B1. is

```
==CPY_0(TEXTJOIN(" ",1,"from A01_ExamplesPython.B18_FunctionsAndCurvesPlots.C01_Intro_Parametric2D import D07_
↪DistPlotContinuous $n importlib.reload(D07_DistPlotContinuous) $n  D07_DistPlotContinuous.DistPlotBeta(target=",B3,", a=",
↪B4,", b=",B5,", Title=",B6,", OutputMode = 'svg'",  ")"," $n result='Beta distribution'"))
```

This formula calls the function DistPlotBeta from the module D07_DistPlotContinuous in the package A01_ExamplesPython.B18_FunctionsAndCurvesPlots.C01_Intro_Parametric2D. The parameters of this function are taken from the cells B3 to B8. The result is a CSV file named TTest1External.csv which is written to the Output Monitor folder. The corresponding Python code with conventional formatting and substitution of the referenced cell values would look like this:

```
from A01_ExamplesPython.B18_FunctionsAndCurvesPlots.C01_Intro_Parametric2D import D07_DistPlotContinuous
importlib.reload(D07_DistPlotContinuous)
```

(continues on next page)

(continued from previous page)

```
D07_DistPlotContinuous.DistPlotBeta(target='pdf', a=[5, 10.0, 20.5], b=[20.5, 10.0, 5], Title='Beta distribution',␣
↪OutputMode = 'svg')
result='Beta distribution'
```

Note

Here we are using `importlib.reload` to make sure that any changes in the code of the module `D07_DistPlotContinuous` which may have occured since the last use of this spreadsheet function become effective without restarting the Python interpreter.

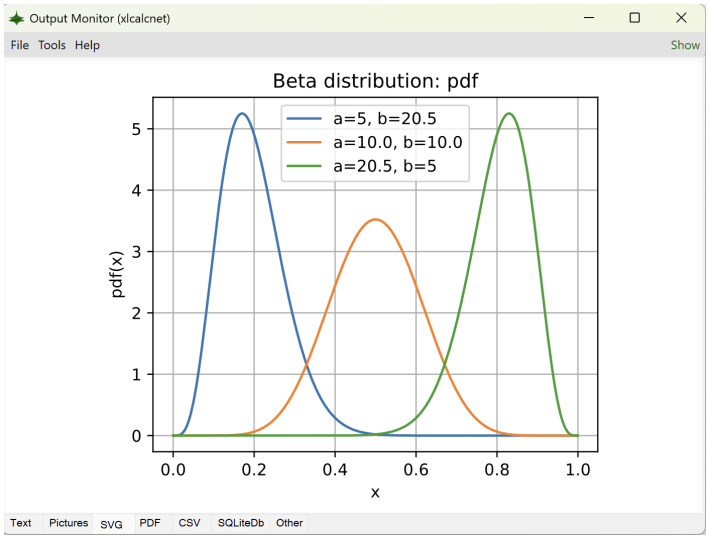
The cell `A3` contains `="target:"`, and the cell `B3` contains `="pdf"`. This passes the string `"pdf"` as the parameter `target` to the function `DistPlotBeta`.

The cell `A4` contains `="a:"`, and the cell `B4` contains `="[5, 10.0, 20.5]"`. This passes This passes the list `[5, 10.0, 20.5]` as the parameter `a` to the function `DistPlotBeta`.

The cell `A5` contains `="b:"`, and the cell `B5` contains `="[20.5, 10.0, 5]"`. This passes the list `[20.5, 10.0, 5]` as the parameter `b` to the function `DistPlotBeta`.

The cell `A6` contains `="Title:"`, and the cell `B6` contains `="Beta distribution"`. This passes the string `"Beta distribution"` as the keyword argument `Title` to the function `DistPlotBeta`.

And this is the Output Monitor showing the result (with the project panel hidden)



1.2.4 Using dynamic arrrays in MS Excel

Note

In the following subsection we will work with the file `XlDemoCPYdyn.xlsx`, which contains an example of using dynamic arrays in MS Excel with XlCalcNet. Examples for using MS Excel with the Python standard library start *here*, and more advanced examples using Numpy, Matplotlib, Pandas, Scipy, Seaborn and XlCalcNet start *here*.

1.2.4.1 The worksheet “Student_t_1sample_test”

Dynamic arrays are only supported in MS Excel 365 and MS Excel 2021 or later. In these versions, the output of a function can be an array, which is then automatically “spilled” into the cells below and to the right of the cell containing the formula. The size of the output array can be changed by changing the input parameters of the function.

The worksheet "Student_t_1sample_test" demonstrates the use of dynamic arrays in Excel with XlCalcNet.

This is a snapshot of the worksheet "Student_t_1sample_test" with the formula in cell `A11`, which is also where the output is starting. The main difference to the example with `*.csv` output is that now in "Options" we have `OutputMode='list'` and not `OutputMode='csv'`.

	A	B	C	D	E	F

31						

The formula in the cell `A11` is

```
=CPY_0(TEXTJOIN(" ",1,"from A06_UserlibExamplesPython.B29_InferentialStatistics.C01_BasicTests1Sample import D01_StudentT_
↪PValues $n importlib.reload(D01_StudentT_PValues) $n  D01_StudentT_PValues.stats_student_t_1sample_test(n=",B3,", mu0=",B4,
↪", mean=",B5,", std=",B6,", alpha=", B7, B8, ")"," $n result='Students t-test, 1 sample'"))
```

This formula calls the function `stats_student_t_1sample_test` from the module `D01_StudentT_PValues` in the package `A06_UserlibExamplesPython.B29_InferentialStatistics.C01_BasicTests1Sample`. The parameters of this function are taken from the cells `B3` to `B8`. The result is a Python list, which is displayed as a dynamic array. The corresponding Python code with conventional formatting and substitution of the referenced cell values would look like this:

```
from A06_UserlibExamplesPython.B29_InferentialStatistics.C01_BasicTests1Sample import D01_StudentT_PValues
importlib.reload(D01_StudentT_PValues)
D01_StudentT_PValues.stats_student_t_1sample_test(n=[10, 20, 30], mu0=1.0, mean=[4.5,4.7], std=[1,2,3,14], alpha=0.015,␣
↪I=True, D=True, T=True, C=True, Onesided=True, Twosided=True, OutputMode='list')
result='Students t-test, 1 sample'
```

Note

Here we are using `importlib.reload` to make sure that any changes in the code of the module `D01_StudentT_PValues` which may have occured since the last use of this spreadsheet function become effective without restarting the Python interpreter.

The cell `A3` contains `="n:"`, and the cell `B3` contains `="[10, 20, 30]"`. This passes the list `[10, 20, 30]` as the parameter `n` to the function `stats_student_t_1sample_test`.

The cell `A4` contains `="mu0:"`, and the cell `B4` contains `="1.0"`. This passes the value `1.0` as the parameter `mu0` to the function `stats_student_t_1sample_test`.

The cell `A5` contains `="mean:"`, and the cell `B5` contains `="[4.5,4.7]"`. This passes the list `[4.5,4.7]` as the parameter `mean` to the function `stats_student_t_1sample_test`.

The cell `A6` contains `="std:"`, and the cell `B6` contains `="[1,2,3,14]"`. This passes the list `[1,2,3,14]` as the parameter `std` to the function `stats_student_t_1sample_test`.

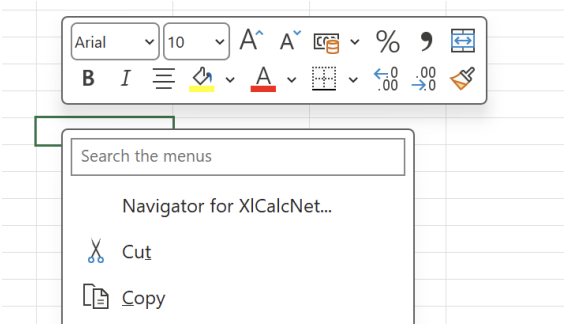
The cell `A7` contains `="alpha:"`, and the cell `B7` contains `="0.015"`. This passes the value `0.015` as the parameter `alpha` to the function `stats_student_t_1sample_test`.

The cell `A8` contains `="Options:"`, and the cell `B8` contains `=",I=True, D=True, T=True, C=True, Onesided=True, Twosided = True, OutputMode='csv'"`. This passes the options `I=True, D=True, T=True, C=True, Onesided=True, Twosided = True, OutputMode='list'` as keyword arguments to the function `stats_student_t_1sample_test`.

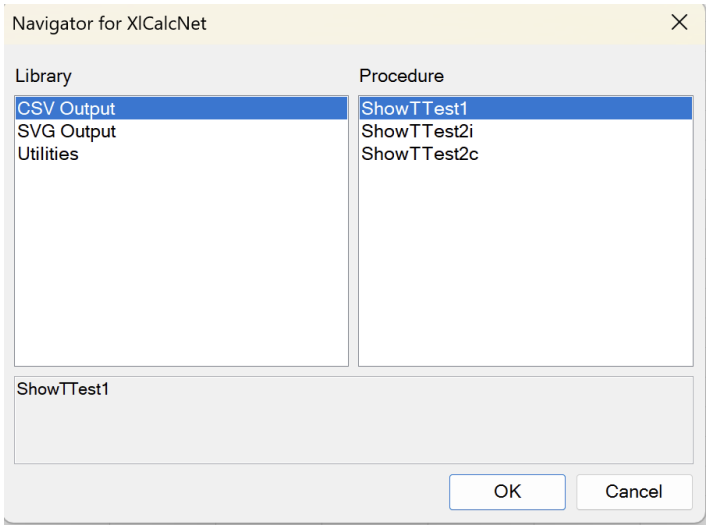
1.2.5 Managing procedures instead of functions

It is possible to call the spreadsheet functions `CPY_0` to `CPY_9` from LibreOffice Basic and to use this to start procedures instead of functions. A few simple examples have already been prepared to demonstrate the technique.

To access the relevant dialog, click on the XlCalcNet logo (in orange) on the main menu bar:



The following dialog box with the title **Navigator for XlCalcNet** will appear:



The first example, with `CSV Output` in "Category" and `ShowTTest1` in "Subroutine", will write a CSV file into the `XlCalcNetIDE\OutputMonitor` folder in the AppDataLocal folder. In order to see it, we need to open the `Output Monitor` application: start the `Tiny IDE` by clicking on its icon in the task bar, and in the main menu, click on `Tools -> Start Output Monitor`. With the `Output Monitor` application running, click `OK`. The CSV file will then immediately appear in the `Output Monitor`.

The corresponding code in the module `MpFunlabLocal -> BasicAndDialogs` is shown below:

```
Sub ShowTTest1()
    Rem Output (a .csv file) is shown in output monitor
    Code = "from A06_UserlibExamplesPython.B29_InferentialStatistics.C01_BasicTests1Sample import D01_StudentT_PValues;"
    Code = Code + "D01_StudentT_PValues.demo_stats_student_t_1sample_test(); result='Done';"
    Result = Application.Run("CPY_0", Code)
    showResult (Result)
End Sub
```

The second example, with `SVG Output` in "Category" and `ShowPolygon` in "Subroutine", will write a SVG file into the `XlCalcNetIDE\OutputMonitor` folder in the AppDataLocal folder. With the `Output Monitor` application running (see above), click `OK`. The SVG file will then immediately appear in the `Output Monitor`.

The corresponding code in the module `MpFunlabLocal` -> `BasicAndDialogs` is shown below:

```
Sub ShowPolygon()
    Rem Graphics is shown in output monitor
    Code = "from A01_ExamplesPython.B18_FunctionsAndCurvesPlots.C02_BasicCurves import D01_RegularConvexPolygon;"
    Code = Code + "D01_RegularConvexPolygon.RegularConvexPolygon(OutputMode='svg'); result='Done';"
    Result = Application.Run("CPY_0", Code)
    showResult (Result)
End Sub
```

1.2.6 Uninstalling

To uninstall these two Add-ins properly, follow these steps: Within MS Excel, on an Excel worksheet, open the Add-ins dialog from the main menu/ribbon: `Developer` -> `Excel Add-ins`. In the Add-ins dialog, unselect `MpFunlab` and `Mpfunlablocal`, and click on `OK`. Close MS Excel. When Excel is started the next time these Add-ins will not be loaded, however, they will still appear (unselected) in the Add-ins dialog (this seems to be a decade-old bug/feature). To remove them also from the Add-ins dialog, you need to rename them in their original location, start Excel again, and start the Add-ins dialog again. When you then re-select these unselected items, a dialog stating that the add-in cannot be found will appear, followed by "Delete from list?". Click on Yes, and the add-in will be removed from the list.

1.3 Using XlCalcNet within LibreOffice Calc

1.3.1 Preparing LibreOffice Calc for using XlCalcNet

To enable the use of XlCalcNet in LibreOffice Calc, two extensions need to be installed: the first, named `MpfunlabLocal.oxt`, contains functions and dialogs written in LibreOffice Basic and is intended to be modified by the user during normal use. The second, named `Mpfunlab.oxt`, contains the functionality behind the spreadsheet functions `APY0` - `APY9` and `ASDOUBLE`. It has been compiled using the SDK of LibreOfffice 7.4 and is NOT intended to be modified by the user during normal use. Both extensions are located in a subfolder of the `DataXlCalcNet` folder in the `Documents` folder: `DataXlCalcNet\SpreadsheetAddins\LibreOfficeCalc`.

1.3.1.1 Installing MpfunlabLocal.oxt and Mpfunlab.oxt

To install these two extensions properly, following the correct order is important. First install `MpfunlabLocal.oxt` within a normally launched LibreOffice Calc (i.e. without administrator privileges): Open the Extension dialog from the main menu:`Tools -> Extensions...`. In the Extension dialog click the `Add` button and in the `Documents` folder navigate to the folder `DataXlCalcNet\SpreadsheetAddins\LibreOfficeCalc`. Double- click on `MpfunlabLocal.oxt`. Then click on the `Close` button in the Extension dialog. In the dialog `Restart LibreOffice`, click on `Restart Now`. This will close LibreOffice Calc and will open the general LibreOffice desktop. Exit LibreOffice.

Now start LibreOffice with administrator privileges: Right-click on the desktop icon of LibreOffice and select `Run as administrator`. In the following dialog, confirm that you want to proceed. In the LibreOffice desktop, open a `Calc Spreadsheet`. Open the Extension dialog from the main menu:`Tools -> Extensions...`. In the Extension dialog click the `Add` button and in the `Documents` folder navigate to the folder `DataXlCalcNet\SpreadsheetAddins\LibreOfficeCalc`. Double- click on `Mpfunlab.oxt`. In the following dialog box "For whom do you want to install the extension?", click on `For all users`. In the following "License Agreement" dialog, click on `Accept`. Then click on the `Close` button in the Extension dialog. In the dialog `Restart LibreOffice`, click on `Restart Now`. This will close LibreOffice Calc and will open the general LibreOffice desktop. Exit LibreOffice.

Within a normally launched LibreOffice Calc, open the Macro Editor from the main menu: `Tools -> Macros -> Edit Macros...` In the Object Catalog of the Macro Editor, select `My Macros & Dialogs -> MpFunlabLocal -> CallsFromPython`: In the function `GetCPythonExeDirLocal` set the path of the external Python installation which matches the main internal Python version, e.g. `GetCPythonExeDirLocal ="C:\Python313"`. Then close the Macro Editor.

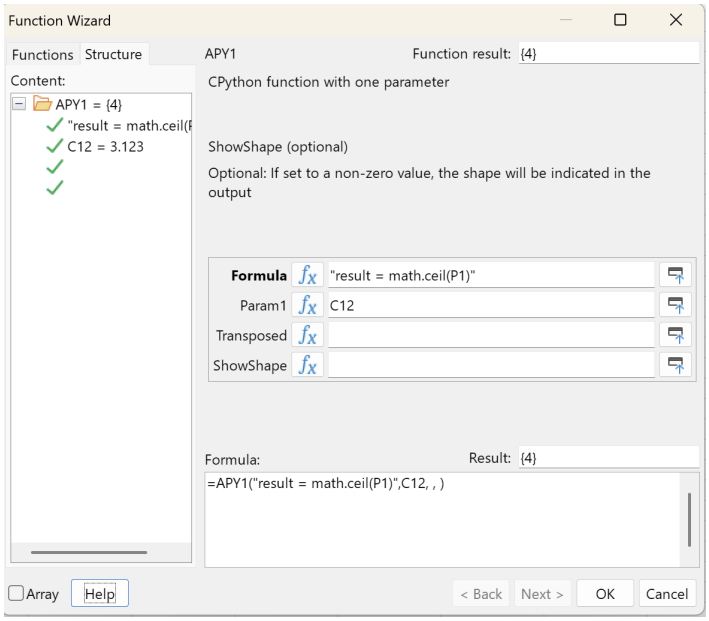
1.3.2 Using the Python standard library functions within spreadsheet formulas

> **Note**
>
> In the following subsections, we will work with the file `LoDemoAPYstd.ods`, which contains examples for using the Python standard library. More advanced examples using Numpy, Matplotlib, Pandas, Scipy, Seaborn and XlCalcNet start *here*.

Within LibreOffice Calc, open from the main menu `File -> Open` in the Documents folder the LibreOffice Calc workbook `DataXlCalcNet\DataExamples\MainExamples\Workbooks\LoDemoAPYstd.ods`.

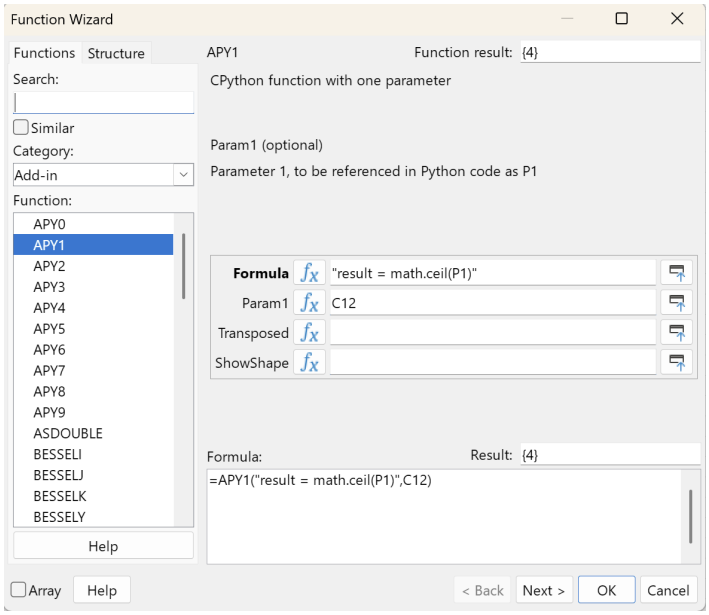
This file contains several worksheets which demonstrate different possibilities of using the Python standard library within Libreoffice Calc spreadsheet formulas.

Before we start with that we will briefly explore the use of these functions with the Function Wizard of LibreOffice Calc: In the worksheet "Math", select cell `B12` and click on the icon of the Function Wizard in the Formula Bar. This opens the Function Wizard with the Structure tab selected:



We see that the formula in the spreadsheeet cell is `=APY1("result = math.ceil(P1)",C12)`. The function `APY1` has a required string parameter, `Formula`, which contains a Python script. This python script can contain several Python statement. The last statement is always expected to assign a value to the variable result, in this case a Python float, which is coverted to a floating point number in double precision (a "Double") in LibreOffice. The next optional parameter, `Param1`, can be a string, a Double, a Boolean value or a reference. In this case, it is a reference (`C12`) which points to a Double with the value `3.123`. This optional parameter, `Param1`, is referenced in the Python formula given above as `P1`. The last but one parameter, `Transposed`, and the last parameter, `ShowShape`, are only relevant when arrays are returned; this is discussed *here*.

If we open the Functions tab, the Functions wizard looks like this:



We see that the function `APY1` is in the Category "Add-in", and that there are 10 functions, `APY0` to `APY9`, which differ only by the number of parameters `Param1` to `Param9` which they support (The function `APY0` does not have a parameter `Param0`). There is also a function `ASDOUBLE`, which is used to convert string representations of a Python Fraction or Decimal into a Double; this is discussed *here*.

1.3.2.1 The worksheet "GeneralInfo"

The worksheet "GeneralInfo" contains calls to the Python modules `os`, `platform` and `sys`.

For example, the cell `B4` contains the formula `=APY0("result = platform.processor()")`. The function result depends on the hardware, e.g. `Intel64 Family 6 Model 165 Stepping 5, GenuineIntel`.

The cell `B16` contains the formula `=APY0("result = os.getcwd()")`. The function result depends on the LibreOffice installation, e.g. `C:\Program Files\LibreOffice\program`.

The cell `B33` contains the formula `=APY0("result = str(sys.float_info.epsilon)")`, which return the machine epsilon in double precision. The function result is: `2.220446049250313e-16`.

1.3.2.2 The worksheet "Math"

The worksheet "Math" demonstrates the use of the Python module `math` and the use of parameters in functions.

For example, the cell `B33` contains the formula `=APY1("result = math.exp(P1)-1",C33)`, which calculates $\exp(\mathrm{P1}) - 1$ naively. The function result is `1.00000500000696E-05`, with the cell `C33` containing the value `0.00001`.

The cell `B34` contains the formula `=APY1("result = math.expm1(P1)",C34)`, which calculates $\exp(\mathrm{P1}) - 1$ using the `expm1` function. The function result is `1.00000500001667E-05`, with the cell `C34` again containing the value `0.00001`.

The floating point values `NaN`, `+inf` and `-inf` are not supported in spreadsheet programs, which only return `#NUM!` in these cases. Use the string representation instead. This is shown in the cells `A4:B9` on this worksheet.

The cell `B36` contains the formula `=APY2("result = math.log(P1, P2)",C36, D36)`, with the cell `C36` containing the value `3.123` and the cell `D36` containing the value `10`. The function result is: `0.494571984230199`.

1.3.2.3 The worksheet "Arrays"

The worksheet "Arrays" demonstrates the use of arrays in functions. The Python equivalent of arrays are lists.

For example, the cell `B3` contains the formula `=APY0("result = str(sys.path)")`. The function `sys.path` returns a list of strings (containing the entries of the Python path), which is converted into one string by writing `str(sys.path)`. This makes sure that the result can be displayed in one cell, but the result string is quite long and hard to read.

We can use an array formula to improve readability. We recall that in addition to the usual parameters `P1` - `P9` in the functions `APY0` to `APY9` there are two more: The last but one paramter, named `Transposed`, which is optional with default value 0, where a non-zero value means that the returned array should be transposed; and the last paramter, named `ShowShape`, which is optional with default value 0, where a non-zero value means that the shape of the returned array should be indicated like `R7C3` for an array with 7 rows and 3 columns.

As an example, the cell `B6` contains the formula `=APY0("result = sys.path",1,1)` and returns the shape information `R12C1` followed by the separator `|`, followed by the first entry of the transposed array, i.e. in this case `R12xC1| C:\Users\DUHad\Documents\DataXlCalcNet`.

We can build the corresponding array formula by first selecting a range like `R12C1`, then typing in the input line of the formula bar `=APY0("result = sys.path",1,0)`, and finally, while keeping the shift and control keys pressed down, pressing the enter key.

This is what has been done in cells `B9:B20`. The formula is now displayed as `{=APY0("result = sys.path",1,0)}`, with curly braces, to indicate that it is an array formula. We can change the range which is covered by the array formula by dragging the small blue rectangle in the lower right corner in the selected range (see the screenshot below).

4	C:\Users\DUHad\Documents\DataXlCalcNet
5	C:\Python313\Lib\site-packages
6	C:\Python313\Lib
7	C:\Python313\DLLs
8	C:\Python313
9	C:\Program Files\LibreOffice\program\python-core-3.13.15\lib
10	C:\Program Files\LibreOffice\program\python-core-3.13.15\lib\site-packages
11	C:\Program Files\LibreOffice\program
12	C:\Program Files\LibreOffice\program\python313.zip
13	C:\Program Files\LibreOffice\program\Lib
14	C:\Windows\Microsoft.NET\Framework64\v4.0.30319\
15	C:\Program Files\LibreOffice\share\extensions\dict-en\pythonpath
16	

1.3.2.4 The worksheet "Data"

The worksheet "Data " demonstrates the use of named ranges in LibreOffice Calc spreadsheet formulas.

Currently there a two small datasets with predefined as named ranges: `matA` defined as the range $Data.$A$3:$A$7 and `matB` defined as the range $Data.$A$3:$A$7.

These ranges are used in the workbook "Arrays".

1.3.3 Using Numpy, Matplotlib, Pandas, Scipy, Seaborn and XlCalcNet within spreadsheet formulas

> **Note**
>
> In the following subsections. we will work with the file `LoDemoAPYadv.ods`, which contains more advanced examples using Numpy, Matplotlib, Pandas, Scipy, Seaborn and XlCalcNet. Examples for using LibreOffice Calc with the Python standard library start *here*.

Within LibreOffice Calc, open from the main menu `File -> Open` in the Documents folder the LibreOffice Calc workbook `DataXlCalcNet\DataExamples\MainExamples\Workbooks\LoDemoAPYadv.ods`.

This file contains several worksheets which demonstrate different possibilities of using Numpy, Matplotlib, Pandas, Scipy, Seaborn and XlCalcNet within Libreoffice Calc spreadsheet formulas.

Some of these functions write their output into the `XlCalcNetIDE\OutputMonitor` folder in the AppDataLocal folder. In order to see it, we need to open the `Output Monitor` application: start the `Tiny IDE` by clicking on its icon in the task bar, and in the main menu, click on `Tools -> Start Output Monitor`.

1.3.3.1 The worksheet "FractionsInput"

The worksheet "FractionsInput " demonstrates the use of the Python data type `Fraction` in LibreOffice Calc spreadsheet formulas.

25					

If we try to enter a number like `123456789012345678/901234567890`, i.e. a number with more than 16 digits into a spreadsheet cell, it will automatically be shortened to `1.23456789012346E+029`. In order to be able to enter such numbers into spreadsheet cells, the cells must first be formatted as text, and thereafter these numbers can be entered as text. This is mostly useful when working with Python Fractions and Decimals.

However, this kind of input is hard to read; it is also not directly usable for numerical spreadsheet functions. This can be changed by using the function `ASDOUBLE`, a shown in column `B`

As an example, worksheet "FractionsInput" contains a named range called "MpInputFractions" in column `A`, which can be used as input for descriptive statistics or linear algebra routines.

The module `npm` of XlCalcNet can be used to calculate desciptive statistics, like `prod`, `sum`, `mean`, `median`, `variance` with fractions. The function `npm.mean` can be called from a spreadsheet cell as follows:

```
=APY1("from xlcalcnet import npm, qpm $n x = npm.array(P1, dtype=qpm); result=str(npm.prod(x))",MpInputFractions)
```

Às before, we are using `$n` for newline and `$t` for indentation. The result is itself a `Fraction` (converted to a string), and is exact. The corresponding Python code with conventional formatting would look like this (where `P1` is the input range):

```
from xlcalcnet import npm, qpm
x = npm.array(P1, dtype=qpm)
result=str(npm.prod(x))
```

Note that the input range is converted into a Numpy array with data type `qpm`, which is the data type for rational numbers in XlCalcNet. The result is then converted into a string, so that it can be displayed in a spreadsheet cell.

Since the string output is quite long, we can use `result=float(npm.prod(x))` instead of `result=str(npm.prod(x))` to get a floating point number in double precision, which is more readable. However, this will not be exact anymore.

1.3.3.2 The worksheet "DecimalsInput"

The worksheet "DecimalsInput " demonstrates the use of the Python data type `Decimal` in LibreOffice Calc spreadsheet formulas.

26					

If we try to enter a number like `12345678901234567.901234567890`, i.e. a number with more than 16 digits into a spreadsheet cell, it will automatically be shortened to `1.23456789012346E+017`. In order to be able to enter such numbers into spreadsheet cells, the cells must first be formatted as text, and thereafter these numbers can be entered as text. This is mostly useful when working with Python Fractions and Decimals.

However, this kind of input is hard to read; it is also not directly usable for numerical spreadsheet functions. This can be changed by using the function `ASDOUBLE`, a shown in column `B`

As an example, worksheet "DecimalsInput" contains a named range called "MpInputDecimals" in column `C`, which can be used as input for descriptive statistics or linear algebra routines.

The module `npm` of XlCalcNet can be used to calculate desciptive statistics, like `prod`, `sum`, `mean`, `median`, `variance` with decimals. The function `npm.mean` can be called from a spreadsheet cell as follows:

```
=APY2("from xlcalcnet import npm, dpm $n dpm.dps=int(P2); x = npm.array(P1, dtype=dpm); result=str(npm.mean(x))",
↪MpInputDecimals, $B$2)
```

As before, we are using `$n` for newline and `$t` for indentation. The result is itself a `Decimal` (converted to a string), and is correct to the number of digits specified. The corresponding Python code with conventional formatting would look like this (where `P1` is the input range and `P2` is the number of digits):

```
from xlcalcnet import npm, dpm
dpm.dps=int(P2)
x = npm.array(P1, dtype=dpm)
result=str(npm.mean(x))
```

Note that the input range is converted into a Numpy array with data type `dpm`, which is the data type for decimal numbers in XlCalcNet. The result is then converted into a string, so that it can be displayed in a spreadsheet cell.

Since the string output is quite long, we can use `result=float(npm.prod(x))` instead of `result=str(npm.prod(x))` to get a floating point number in double precision, which is more readable. However, this will then be correct only to the precision of a double-precision floating-point number.

1.3.3.3 The worksheet "Programming"

The worksheet "Programming" demonstrates the use of small python scripts in LibreOffice Calc spreadsheet formulas.

	A	B	C	D
1				
2				
3	**Python standard library: simple loop**			
4	**n:**	45		
5	**Result:**	1980		
6				
7				
8				
9				
10	**Scipy: Numerical quadrature; f(x) = a*x**2 + b**			
11	**Integral start:**	-1.4		
12	**Integral end:**	1.5		
13	**Parameter a:**	2.1		
14	**Parameter b:**	1.1		
15	**Result (integral, error estimate):**	(7.473300000000001, 8.297029729931183e-14)		
16	**Result (integral only):**	7.4733		
17	**Result (error estimate only):**	8.29702973E-14		
18				
19				

The first example in this worksheeet shows how to program a simple loop. The formula in the cell `B4`. is

```
=APY1("temp = 0 $n for i in range(int(P1)): $n$t temp += i $n result = 2 * temp", B4)
```

The cell `B4` contains the value `45`; the result is `1980`. The corresponding Python code with conventional formatting would look like this(where `P1` is `n`, the number of iterations):

```
temp = 0
for i in range(int(P1)):
    temp += i
result = 2 * temp
```

The second example in this worksheet shows how to perform numerical integration.The formula in the cell `B15`. is

```
=APY4("from scipy.integrate import quad $n def integrand(x, a, b): return a*x**2 + b $n a = float(P3); b = float(P4);  $n I␣
↪= quad(integrand, float(P1), float(P2), args=(a,b))   $n result = str(I) ", B11, B12, B13, B14)
```

This formula calls the function `quad` from the module `scipy.integrate` in the package `scipy`. The parameters of this function are taken from the cells `B11` to `B14`. The result is a tuple containing the intergral and an error estimate. The corresponding Python code with conventional formatting would look like this (with P1 is the lower limit of integration, P2 is the upper limit, P3 is the coefficient of x^2, and P4 is the constant term):

```
from scipy.integrate import quad
def integrand(x, a, b): return a*x**2 + b
a = float(P3); b = float(P4)
I = quad(integrand, float(P1), float(P2), args=(a,b))
result = str(I)
```

The cells `B16` to `B17` show the same result as an array formula, with `B16` containing the integral and `B17` the error estimate.

1.3.3.4 The worksheet "OutputMonitorCSV"

This is a snapshot of the worksheet "OutputMonitorCSV" with the relevant formula in cell `B1`. The output of the formula in cell `B1` is a CSV file named `TTest1External.csv` which is written to the Output Monitor folder. The Output Monitor application must be running in order to see the output. The Output Monitor can be started from the main menu of the Tiny IDE by clicking on `Tools -> Start Output Monitor`.

	A	B	C	D	E	F	G	H
1	**Python Script:**	Students t-test, 1 sample						
2								
3	**n:**	[10, 20, 30]						
4	**mu0:**	1.0						
5	**mean:**	[4.5,4.7]						
6	**std:**	[1,2,3,4]						
7	**alpha:**	0.05						
8	**Options:**	,I=True, D=True, T=True, C=True, Onesided=True, Twosided = True, OutputMode='csv'						
9								
10								
11								
12	**Note:**	The result is written to the Output Monitor folder (start the Output Monitor application first!)						
13								

The formula in the cell `B1`. is

```
=APY0(TEXTJOIN(" ",1,"from A06_UserlibExamplesPython.B29_InferentialStatistics.C01_BasicTests1Sample import D01_StudentT_
↪PValues $n importlib.reload(D01_StudentT_PValues) $n D01_StudentT_PValues.stats_student_t_1sample_test(n=",B3,", mu0=",B4,
↪", mean=",B5,", std=",B6,", alpha=", B7, B8, ")"," $n result='Students t-test, 1 sample'"))
```

This formula calls the function `stats_student_t_1sample_test` from the module `D01_StudentT_PValues` in the package `A06_UserlibExamplesPython.B29_InferentialStatistics.C01_BasicTests1Sample`. The parameters of this function are taken from the cells `B3` to `B8`. The result is a CSV file named `TTest1External.csv` which is written to the Output Monitor folder. The corresponding Python code with conventional formatting and substitution of the referenced cell values would look like this:

```
from A06_UserlibExamplesPython.B29_InferentialStatistics.C01_BasicTests1Sample import D01_StudentT_PValues
importlib.reload(D01_StudentT_PValues)
D01_StudentT_PValues.stats_student_t_1sample_test(n=[10, 20, 30], mu0=1.0, mean=[4.5,4.7], std=[1,2,3,14], alpha=0.015,␣
↪I=True, D=True, T=True, C=True, Onesided=True, Twosided=True, OutputMode='csv')
result='Students t-test, 1 sample'
```

> **Note**
>
> Here we are using `importlib.reload` to make sure that any changes in the code of the module `D01_StudentT_PValues` which may have occured since the last use of this spreadsheet function become effective without restarting the Python interpreter.

The cell `A3` contains `="n:"`, and the cell `B3` contains `="[10, 20, 30]"`. This passes the list `[10, 20, 30]` as the parameter `n` to the function `stats_student_t_1sample_test`.

The cell `A4` contains `="mu0:"`, and the cell `B4` contains `="1.0"`. This passes the value `1.0` as the parameter `mu0` to the function `stats_student_t_1sample_test`.

The cell `A5` contains `="mean:"`, and the cell `B5` contains `="[4.5,4.7]"`. This passes the list `[4.5,4.7]` as the parameter `mean` to the function `stats_student_t_1sample_test`.

The cell `A6` contains `="std:"`, and the cell `B6` contains `="[1,2,3,14]"`. This passes the list `[1,2,3,14]` as the parameter `std` to the function `stats_student_t_1sample_test`.

The cell `A7` contains `="alpha:"`, and the cell `B7` contains `="0.015"`. This passes the value `0.015` as the parameter `alpha` to the function `stats_student_t_1sample_test`.

The cell `A8` contains `="Options:"`, and the cell `B8` contains `=",I=True, D=True, T=True, C=True, Onesided=True, Twosided = True, OutputMode='csv'"`. This passes the options `I=True, D=True, T=True, C=True, Onesided=True, Twosided = True, OutputMode='csv'` as keyword arguments to the function `stats_student_t_1sample_test`.

And this is the Output Monitor showing the result (with the project panel hidden)

1.3.3.5 The worksheet "OutputMonitorSVG"

This is a snapshot of the worksheet "OutputMonitorSVG" with the relevant formula in cell `B1`. The output of the formula in cell `B1` is a SVG file named `D07_DistPlotContinuous.svg` which is written to the Output Monitor folder. The Output Monitor application must be running in order to see the output. The Output Monitor can be started from the main menu of the Tiny IDE by clicking on `Tools -> Start Output Monitor`.

	A	B	C	D	E	F	G
1	**Python Script:**	Beta distribution					
2							
3	**target:**	'pdf'	# 'pdf', 'cdf', 'sf', 'hf', 'chf', 'qtf', 'isf'				
4	**a:**	[5, 10.0, 20.5]					
5	**b:**	[20.5, 10.0, 5]					
6	**Title:**	'Beta distribution'					
7							
8							
9							
10	**Note:**	The result is written to the Output Monitor folder (start the Output Monitor application first!)					
11							

The formula in the cell `B1`. is

```
==APY0(TEXTJOIN(" ",1,"from A01_ExamplesPython.B18_FunctionsAndCurvesPlots.C01_Intro_Parametric2D import D07_
↪DistPlotContinuous $n importlib.reload(D07_DistPlotContinuous) $n  D07_DistPlotContinuous.DistPlotBeta(target=",B3,", a=",
↪B4,", b=",B5,", Title=",B6,", OutputMode = 'svg'",  ")"," $n result='Beta distribution'"))
```

This formula calls the function `DistPlotBeta` from the module `D07_DistPlotContinuous` in the package `A01_ExamplesPython.B18_FunctionsAndCurvesPlots.C01_Intro_Parametric2D`. The parameters of this function are taken from the cells `B3` to `B8`. The result is a CSV file named `TTest1External.csv` which is written to the Output Monitor folder. The corresponding Python code with conventional formatting and substitution of the referenced cell values would look like this:

```
from A01_ExamplesPython.B18_FunctionsAndCurvesPlots.C01_Intro_Parametric2D import D07_DistPlotContinuous
importlib.reload(D07_DistPlotContinuous)
D07_DistPlotContinuous.DistPlotBeta(target='pdf', a=[5, 10.0, 20.5], b=[20.5, 10.0, 5], Title='Beta distribution',␣
↪OutputMode = 'svg')
result='Beta distribution'
```

> **Note**
>
> Here we are using `importlib.reload` to make sure that any changes in the code of the module `D07_DistPlotContinuous` which may have occured since the last use of this spreadsheet function become effective without restarting the Python interpreter.

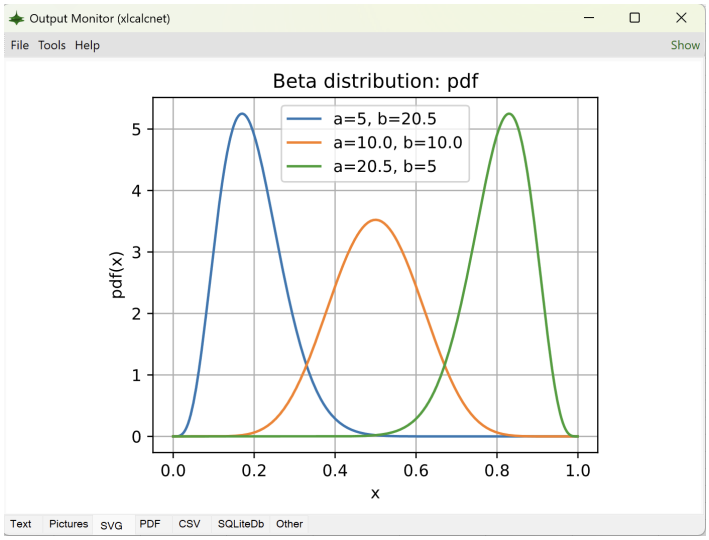
The cell A3 contains ="target:", and the cell B3 contains ="pdf". This passes the string "pdf" as the parameter target to the function DistPlotBeta.

The cell A4 contains ="a:", and the cell B4 contains ="[5, 10.0, 20.5]". This passes This passes the list [5, 10.0, 20.5] as the parameter a to the function DistPlotBeta.

The cell A5 contains ="b:", and the cell B5 contains ="[20.5, 10.0, 5]". This passes the list [20.5, 10.0, 5] as the parameter b to the function DistPlotBeta.

The cell A6 contains ="Title:", and the cell B6 contains ="Beta distribution". This passes the string "Beta distribution" as the keyword argument Title to the function DistPlotBeta.

And this is the Output Monitor showing the result (with the project panel hidden)



1.3.4 Using links to external *.csv, *.xlsx and *.svg files

Note

In the following subsections. we will work with the file LoDemoAPYext.ods, which contains more advanced examples using Numpy, Matplotlib, Pandas, Scipy, Seaborn and XlCalcNet. Examples for using LibreOffice Calc with the Python standard library start *here*.

Within LibreOffice Calc, open from the main menu File -> Open in the Documents folder the LibreOffice Calc workbook \DataXlCalcNet\DataExamples\MainExamples\Workbooks\LoDemoAPYext.ods.

This file contains several worksheets which demonstrate the use of links to external files in such a way that the output is displayed in the spreadsheet. This is demonstrated in the worksheets “ExternalCSV”, “ExternalXlsx” and “ExternalSVG”.

Using links to external files poses a security risk, because it allows the execution of arbitrary code on the local computer. This can be adressed by using “Trusted Locations”: In the main menu, click on Tools -> Options -> LibreOffice -> Security -> Macro Security.... In the dialog “Macro Security”, select the tab “Trusted Sources” and in the section “Trusted File Locations”, click “Add”, and add the path to the folder of the file **containing the links** to the external files (NOT the paths to the external files themselves!). In our case this is the file LoDemoAPYext.ods and the path to the folder containing this file is DataXlCalcNet\DataExamples\MainExamples\Workbooks). Confirm with OK.

Still in the Options dialog, go to LibreOffice Calc -> General. In the section “Update links when opening”, select the item “Always (from trusted locations)” and confirm with OK.

1.3.4.1 The worksheet “ExternalCSV”

The worksheet “ExternalCSV” demonstrates the use of a link to an external `*.csv` file in such a way that the output is displayed in the spreadsheet and is updated automatically when the input data changes. This mimics, to some extend, the use of dynamic arrays in Excel, which are not available in LibreOffice Calc at the time of writing (October 2026).

This is a snapshot of the worksheet “ExternalCSV” with the formula in cell `B1` and the output starting at cell `A10`. The output of the formula in cell `B1` is a CSV file named `TTest1External.csv` which is written to the Output Monitor folder.

30						
31						

The formula in the cell `B1`. is

```
=APY0(TEXTJOIN(" ",1,"from A06_UserlibExamplesPython.B29_InferentialStatistics.C01_BasicTests1Sample import D01_StudentT_
↪PValues $n importlib.reload(D01_StudentT_PValues) $n D01_StudentT_PValues.stats_student_t_1sample_test(n=",B3,", mu0=",B4,
↪", mean=",B5,", std=",B6,", alpha=", B7, B8, ")"," $n result='Students t-test, 1 sample'"))
```

This formula calls the function `stats_student_t_1sample_test` from the module `D01_StudentT_PValues` in the package `A06_UserlibExamplesPython.B29_InferentialStatistics.C01_BasicTests1Sample`. The parameters of this function are taken from the cells `B3` to `B8`. The result is a CSV file named `TTest1External.csv` which is written to the Output Monitor folder. The corresponding Python code with conventional formatting and substitution of the referenced cell values would look like this:

```
from A06_UserlibExamplesPython.B29_InferentialStatistics.C01_BasicTests1Sample import D01_StudentT_PValues
importlib.reload(D01_StudentT_PValues)
D01_StudentT_PValues.stats_student_t_1sample_test(n=[10, 20, 30], mu0=1.0, mean=[4.5,4.7], std=[1,2,3,14], alpha=0.015,␣
↪I=True, D=True, T=True, C=True, Onesided=True, Twosided=True, OutputMode='csv')
result='Students t-test, 1 sample'
```

> **Note**
>
> Here we are using `importlib.reload` to make sure that any changes in the code of the module `D01_StudentT_PValues` which may have occured since the last use of this spreadsheet function become effective without restarting the Python interpreter.

The cell `A3` contains `="n:"`, and the cell `B3` contains `="[10, 20, 30]"`. This passes the list `[10, 20, 30]` as the parameter `n` to the function `stats_student_t_1sample_test`.

The cell `A4` contains `="mu0:"`, and the cell `B4` contains `="1.0"`. This passes the value `1.0` as the parameter `mu0` to the function `stats_student_t_1sample_test`.

The cell A5 contains ="mean:", and the cell B5 contains ="[4.5,4.7]". This passes the list [4.5,4.7] as the parameter mean to the function stats_student_t_1sample_test.

The cell A6 contains ="std:", and the cell B6 contains ="[1,2,3,14]". This passes the list [1,2,3,14] as the parameter std to the function stats_student_t_1sample_test.

The cell A7 contains ="alpha:", and the cell B7 contains ="0.015". This passes the value 0.015 as the parameter alpha to the function stats_student_t_1sample_test.

The cell A8 contains ="Options:", and the cell B8 contains =",I=True, D=True, T=True, C=True, Onesided=True, Twosided = True, OutputMode='csv'". This passes the options I=True, D=True, T=True, C=True, Onesided=True, Twosided = True, OutputMode='csv' as keyword arguments to the function stats_student_t_1sample_test.

To have the output displayed in the spreadsheet, follow these steps:

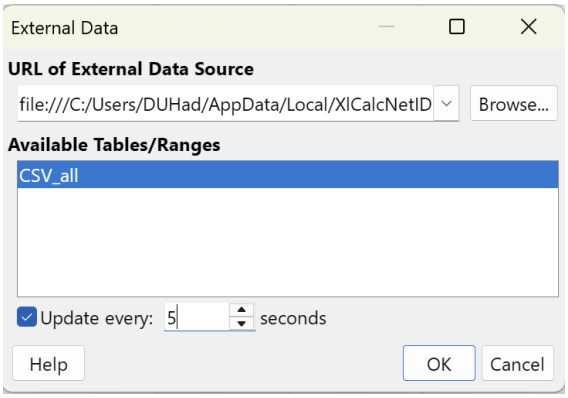
Select the cell where the output should start to be displayed (in this case, cell A10). In the main menu, click on Sheet -> External Links.... In the dialog "External Data", click on Browse.... In the dialog "Insert", select the file TTest1External.csv in the Output Monitor folder and click on Open.

This will open the dialog "Text Import - [TTest1External.csv]".

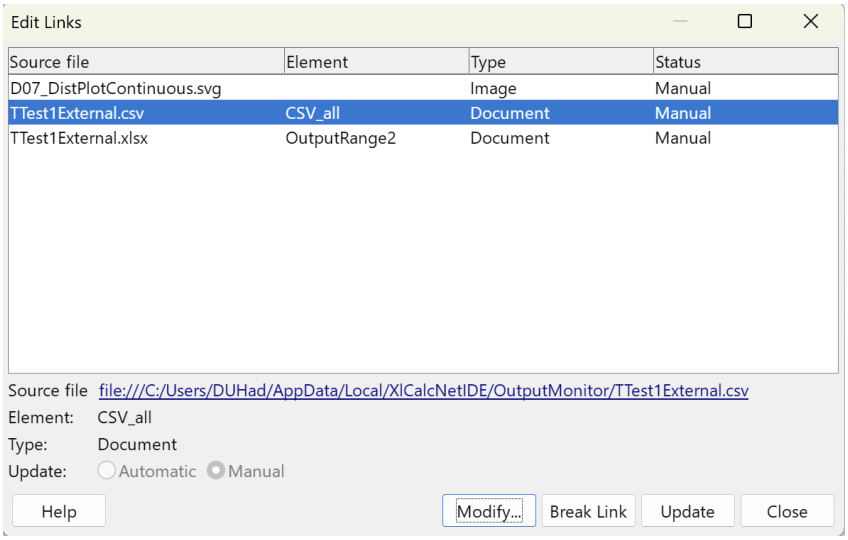
	Standard	Standard	Standard	Standard	Standard
1	Items	Group1	Group2	Group3	Group4
2	n	10.0	20.0	30.0	30.0
3	mean	4.5	4.7	4.7	4.7
4	μ0	1.0	1.0	1.0	1.0
5	stdev	1.0	2.0	3.0	14.0
6	alpha	0.015	0.015	0.015	0.015
7	degrees of freedom	9.0	19.0	29.0	29.0
8	difference of means	3.5	3.7	3.7	3.7
9	rho-tilde = (mean-mu0)/stdev	3.5	1.85	1.233333333	0.2642857143

Make sure that the option "Separated by" is selected, and that the option "Semicolon" is checked. Then click on OK.

Back in the dialog "External Data", check the box "Update every" and and set the time to 5 seconds. The output of the function stats_student_t_1sample_test will now be displayed in the spreadsheet, starting at the cell which was selected when opening the dialog "External Data". And because the option "Update every" is checked, the output will be updated every 5 seconds. If you change any of the parameters in cells B3 to B8, the output will be updated accordingly.



If later on you want to change the settings of the external link, click in the main menu on `Edit -> Links to External Files...`. In the dialog "Edit Links", select the link to the file `TTest1External.csv` and click on `Modify...`. This will open the dialog "External Data" again, where you can change the settings.



1.3.4.2 The worksheet "ExternalXlsx"

The worksheet "ExternalXlsx" demonstrates the use of a link to an external `*.xlsx` file in such a way that the output is displayed in the spreadsheet and is updated automatically when the input data changes. This mimics, to some extend, the use of dynamic arrays in Excel, which are not available in LibreOffice Calc at the time of writing (October 2026).

This is a snapshot of the worksheet "ExternalXlsx" with the formula in cell `B1` and the output starting at cell `A10`. The output of the formula in cell `B1` is an Excel file named `TTest1External.xlsx` which is written to the Output Monitor folder.

30					

The formula in the cell `B1`. is

```
=APY0(TEXTJOIN(" ",1,"from A06_UserlibExamplesPython.B29_InferentialStatistics.C01_BasicTests1Sample import D01_StudentT_
↪PValues $n importlib.reload(D01_StudentT_PValues) $n D01_StudentT_PValues.stats_student_t_1sample_test(n=",B3,", mu0=",B4,
↪", mean=",B5,", std=",B6,", alpha=", B7, B8, ")"," $n result='Students t-test, 1 sample'"))
```

This formula calls the function `stats_student_t_1sample_test` from the module `D01_StudentT_PValues` in the package `A06_UserlibExamplesPython.B29_InferentialStatistics.C01_BasicTests1Sample`. The parameters of this function are taken from the cells `B3` to `B8`. The result is a CSV file named `TTest1External.csv` which is written to the Output Monitor folder. The corresponding Python code with conventional formatting and substitution of the referenced cell values would look like this:

```
from A06_UserlibExamplesPython.B29_InferentialStatistics.C01_BasicTests1Sample import D01_StudentT_PValues
importlib.reload(D01_StudentT_PValues)
D01_StudentT_PValues.stats_student_t_1sample_test(n=[10, 20, 30], mu0=1.0, mean=[4.5,4.7], std=[1,2,3,14], alpha=0.015,␣
↪I=True, D=True, T=True, C=True, Onesided=True, Twosided=True, OutputMode='xlsx')
result='Students t-test, 1 sample'
```

Note

Here we are using `importlib.reload` to make sure that any changes in the code of the module `D01_StudentT_PValues` which may have occured since the last use of this spreadsheet function become effective without restarting the Python interpreter.

The cell `A3` contains `="n:"`, and the cell `B3` contains `="[10, 20, 30]"`. This passes the list `[10, 20, 30]` as the parameter `n` to the function `stats_student_t_1sample_test`.

The cell `A4` contains `="mu0:"`, and the cell `B4` contains `="1.0"`. This passes the value `1.0` as the parameter `mu0` to the function `stats_student_t_1sample_test`.

The cell `A5` contains `="mean:"`, and the cell `B5` contains `="[4.5,4.7]"`. This passes the list `[4.5,4.7]` as the parameter `mean` to the function `stats_student_t_1sample_test`.

The cell `A6` contains `="std:"`, and the cell `B6` contains `="[1,2,3,14]"`. This passes the list `[1,2,3,14]` as the parameter `std` to the function `stats_student_t_1sample_test`.

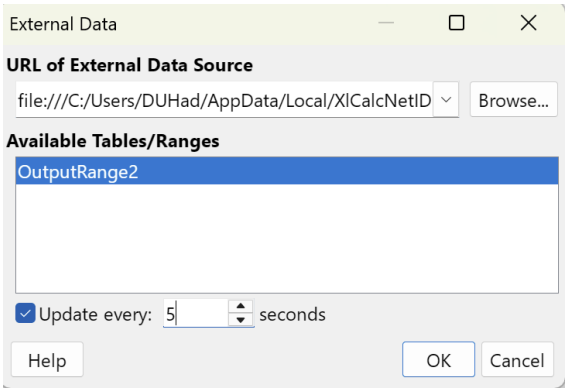
The cell `A7` contains `="alpha:"`, and the cell `B7` contains `="0.015"`. This passes the value `0.015` as the parameter `alpha` to the function `stats_student_t_1sample_test`.

The cell `A8` contains `="Options:"`, and the cell `B8` contains `=",I=True, D=True, T=True, C=True, Onesided=True, Twosided = True, OutputMode='csv'"`. This passes the options `I=True, D=True, T=True, C=True, Onesided=True, Twosided = True, OutputMode='xlsx'` as keyword arguments to the function `stats_student_t_1sample_test`.

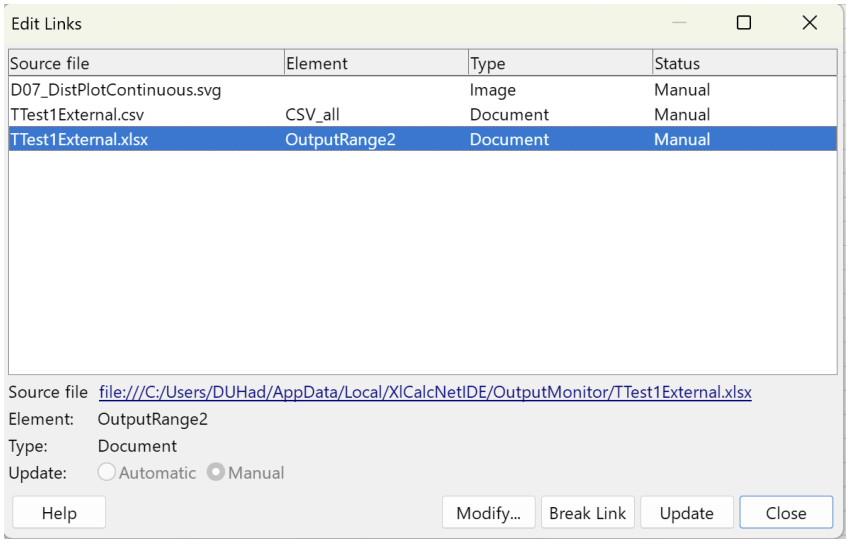
To have the output displayed in the spreadsheet, follow these steps:

Select the cell where the output should start to be displayed (in this case, cell `A10`). In the main menu, click on `Sheet -> External Links...`. In the dialog "External Data", click on `Browse...`. In the dialog "Insert", select the file `TTest1External.xlsx` in the Output Monitor folder and click on `Open`.

Back in the dialog "External Data", check the box "Update every" and and set the time to 5 seconds. The output of the function `stats_student_t_1sample_test` will now be displayed in the spreadsheet, starting at the cell which was selected when opening the dialog "External Data". And because the option "Update every" is checked, the output will be updated every 5 seconds. If you change any of the parameters in cells `B3` to `B8`, the output will be updated accordingly.



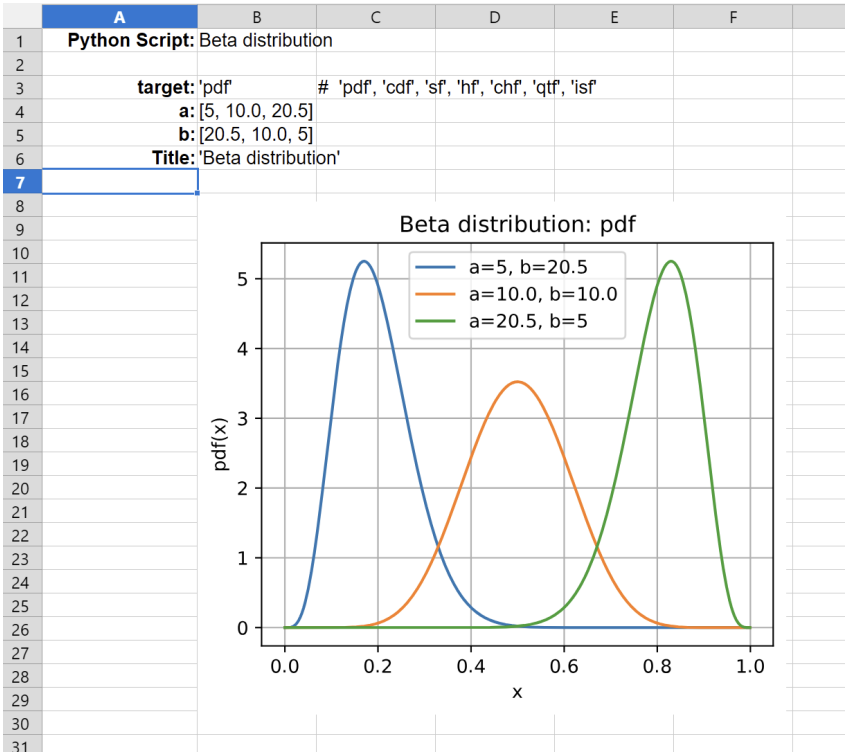
If later on you want to change the settings of the external link, click in the main menu on `Edit -> Links to External Files...`. In the dialog "Edit Links", select the link to the file `TTest1External.xlsx` and click on `Modify...`. This will open the dialog "External Data" again, where you can change the settings.



1.3.4.3 The worksheet "ExternalSVG"

The worksheet "ExternalSVG" demonstrates the use of a link to an external `*.svg` file in such a way that the output is displayed in the spreadsheet and is updated manually when the input data changes.

This is a snapshot of the worksheet "ExternalSVG" with the formula in cell `B1` and the output starting at cell `A10`. The output of the formula in cell `B1` is an SVG file named `D07_DistPlotContinuous.svg` which is written to the Output Monitor folder.



The formula in the cell B1. is

```
==APY0(TEXTJOIN(" ",1,"from A01_ExamplesPython.B18_FunctionsAndCurvesPlots.C01_Intro_Parametric2D import D07_
↪DistPlotContinuous $n importlib.reload(D07_DistPlotContinuous) $n D07_DistPlotContinuous.DistPlotBeta(target=",B3,", a=",
↪B4,", b=",B5,", Title=",B6,", OutputMode = 'svg'",  ")"," $n result='Beta distribution'"))
```

This formula calls the function `DistPlotBeta` from the module `D07_DistPlotContinuous` in the package `A01_ExamplesPython.B18_FunctionsAndCurvesPlots.C01_Intro_Parametric2D`. The parameters of this function are taken from the cells `B3` to `B8`. The result is a CSV file named `TTest1External.csv` which is written to the Output Monitor folder. The corresponding Python code with conventional formatting and substitution of the referenced cell values would look like this:

```
from A01_ExamplesPython.B18_FunctionsAndCurvesPlots.C01_Intro_Parametric2D import D07_DistPlotContinuous
importlib.reload(D07_DistPlotContinuous)
D07_DistPlotContinuous.DistPlotBeta(target='pdf', a=[5, 10.0, 20.5], b=[20.5, 10.0, 5], Title='Beta distribution',␣
↪OutputMode = 'svg')
result='Beta distribution'
```

Note

Here we are using `importlib.reload` to make sure that any changes in the code of the module `D07_DistPlotContinuous` which may have occured since the last use of this spreadsheet function become effective without restarting the Python interpreter.

The cell `A3` contains `="target:"`, and the cell `B3` contains `="pdf"`. This passes the string `"pdf"` as the parameter `target` to the function `DistPlotBeta`.

The cell `A4` contains `="a:"`, and the cell `B4` contains `="[5, 10.0, 20.5]"`. This passes This passes the list `[5, 10.0, 20.5]` as the parameter `a` to the function `DistPlotBeta`.

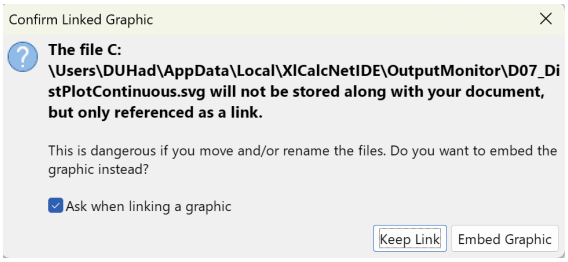
The cell `A5` contains `="b:"`, and the cell `B5` contains `="[20.5, 10.0, 5]"`. This passes the list `[20.5, 10.0, 5]` as the parameter `b` to the function `DistPlotBeta`.

The cell `A6` contains `="Title:"`, and the cell `B6` contains `="Beta distribution"`. This passes the string `"Beta distribution"`

as the keyword argument `Title` to the function `DistPlotBeta`.

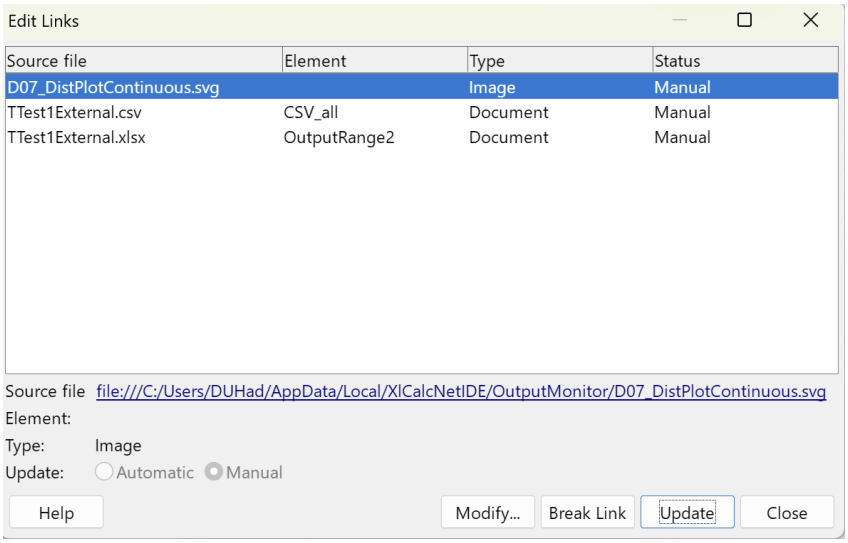
To have the output displayed in the spreadsheet, follow these steps:

In the main menu, click on `Insert -> Image...`. In the dialog "Insert Image", select `Anchor: To page` and then select the file `D07_DistPlotContinuous.svg` in the Output Monitor folder and click on `Open`.



The "Confirm Linked Graphic" dialog will appear. Click on `Keep Link`.

Unfortunately, LibreOffice Calc does not allow to update the linked graphic automatically when the input parameters have changed and the modified `*.svg` file has been written to the Output Monitor folder.

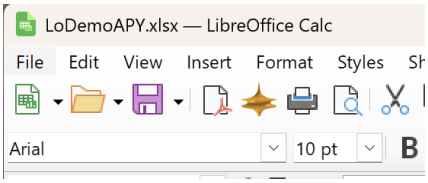


To manually update the linked graphic, click in the main menu on `Edit -> Links to External Files...`. In the dialog "Edit Links", select the link to the file `D07_DistPlotContinuous.svg` and click on `Update`. This will immediately display the updated graphic.

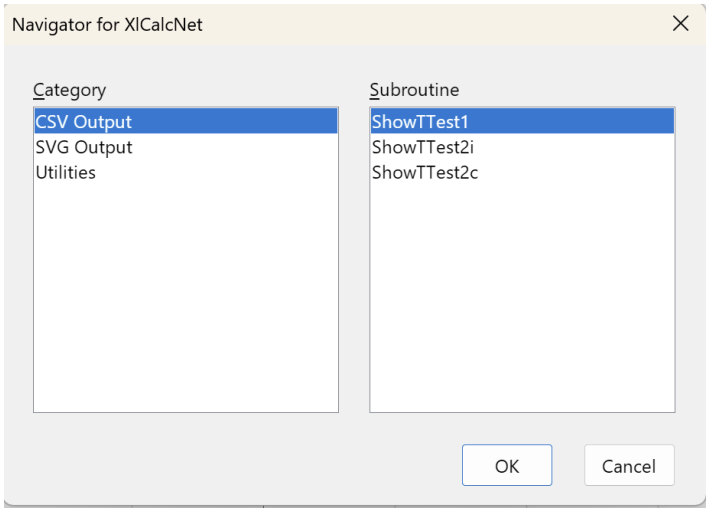
1.3.5 Managing procedures instead of functions

It is possible to call the spreadsheet functions `APY0` to `APY9` from LibreOffice Basic and to use this to start procedures instead of functions. A few simple examples have already been prepared to demonstrate the technique.

To access the relevant dialog, click on the XlCalcNet logo (in orange) on the main menu bar:



The following dialog box with the title **Navigator for XlCalcNet** will appear:



The first example, with `CSV Output` in "Category" and `ShowTTest1` in "Subroutine", will write a CSV file into the `XlCalcNetIDE\OutputMonitor` folder in the AppDataLocal folder. In order to see it, we need to open the `Output Monitor` application: start the `Tiny IDE` by clicking on its icon in the task bar, and in the main menu, click on `Tools -> Start Output Monitor`. With the `Output Monitor` application running, click `OK`. The CSV file will then immediately appear in the `Output Monitor`.

The corresponding code in the module `MpFunlabLocal -> BasicAndDialogs` is shown below:

```
Sub ShowTTest1()
    REM Output (a .csv file) is shown in output monitor
    fa = createUnoService("com.sun.star.sheet.FunctionAccess")
    Code = "from A06_UserlibExamplesPython.B29_InferentialStatistics.C01_BasicTests1Sample import D01_StudentT_PValues;"
    Code = Code + "D01_StudentT_PValues.demo_stats_student_t_1sample_test(); result='Done';"
    ResultArray = fa.callFunction("APY0", Array(Code))
    result = ResultArray(0)(0)
End Sub
```

The second example, with `SVG Output` in "Category" and `ShowPolygon` in "Subroutine", will write a SVG file into the `XlCalcNetIDE\OutputMonitor` folder in the AppDataLocal folder. With the `Output Monitor` application running (see above), click `OK`. The SVG file will then immediately appear in the `Output Monitor`.

The corresponding code in the module `MpFunlabLocal -> BasicAndDialogs` is shown below:

```
Sub ShowPolygon()
    REM Graphics is shown in output monitor
    fa = createUnoService("com.sun.star.sheet.FunctionAccess")
    Code = "from A01_ExamplesPython.B18_FunctionsAndCurvesPlots.C02_BasicCurves import D01_RegularConvexPolygon;"
    Code = Code + "D01_RegularConvexPolygon.RegularConvexPolygon(OutputMode='svg'); result='Done';"
    ResultArray = fa.callFunction("APY0", Array(Code))
    result = ResultArray(0)(0)
End Sub
```

1.3.6 Exporting and uninstalling

1.3.6.1 Exporting changes in MpfunlabLocal to MpfunlabLocal.oxt

Changes which are made in the MpfunlabLocal library are stored in the script folders of LibreOffice and are not automatically saved to MpfunlabLocal.oxt. However, they can be exported to MpfunlabLocal.oxt, so that they are available for installation (re-installation at the current LibreOffice installation or new installation for another LibreOffice installation).

To export the MpfunlabLocal library to MpfunlabLocal.oxt, follow these steps: open the Macro Editor from the main menu of LibreOffice Calc: `Tools -> Macros -> Edit Macros...`. In the main menu of the Macro Editor, select `Dialogs -> Organize Dialogs`. In the dialog "Basic Macro Organizer" select the tab "Libraries". "Location" should be set to "My Macros & Dialogs" and "Library: Name" should be "MpFunlabLocal". Click on `Export...`. In the following dialog box select "Export as extension", and

click on OK. In the dialog "Export library as extension" navigate to the documents folder, and within this folder to DataXlCalcNet\SpreadsheetAddins\LibreOfficeCalc. Select MpfunlabLocal.oxt and click on Save. Confirm to replace. In the dialog "Basic Macro Organizer" click on Close. Then close the Macro Editor.

1.3.6.2 Uninstalling MpfunlabLocal.oxt and Mpfunlab.oxt

To uninstall these two extensions properly, following the correct order is important.

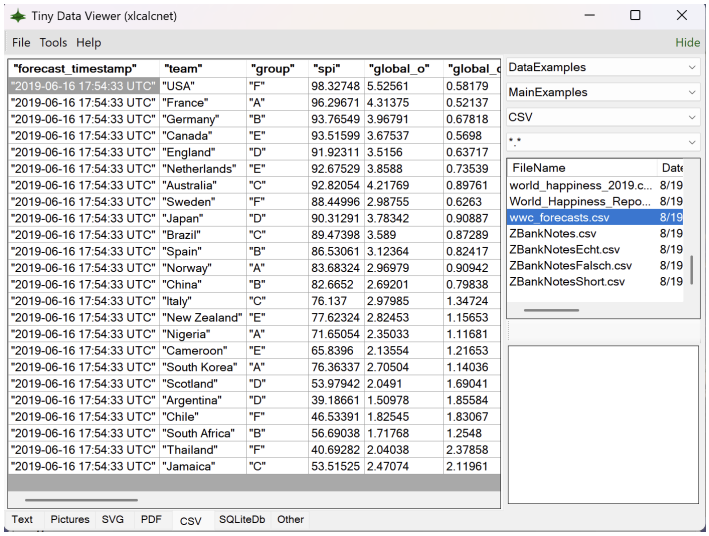
First start LibreOffice with administrator privileges: Right-click on the desktop icon of LibreOffice and select Run as administrator. In the following dialog, confirm that you want to proceed. In the LibreOffice desktop, open a Calc Spreadsheet. Open the Extension dialog from the main menu:Tools -> Extensions.... In the Extension dialog select MpFunlab.oxt, click the Remove button and click on OK in the confirmation dialog. Then click on the Close button in the Extension dialog. In the dialog Restart LibreOffice, click on Restart Now. This will close LibreOffice Calc and will open the general LibreOffice desktop. Exit LibreOffice.

Now uninstall MpfunlabLocal.oxt within a normally launched LibreOffice Calc (i.e. without administrator privileges): Open the Extension dialog from the main menu: Tools -> Extensions.... In the Extension dialog select MpfunlabLocal.oxt, click the Remove button and click on OK in the confirmation dialog. Then click on the Close button in the Extension dialog. In the dialog Restart LibreOffice, click on Restart Now. This will close LibreOffice Calc and will open the general LibreOffice desktop. Exit LibreOffice.

1.4 General user interface and functions

1.4.1 The Tiny Data Viewer

The "Tiny Data Viewer" application is started from the Tiny IDE: in the main menu, click on `Tools -> Tiny Data Viewer`. The screenshot below shows an example



The "Tiny Data Viewer" application is designed around the structure of the `DataXlCalcNet` folder, making it easy to navigate and manage existing data sources, as well a new data provided by the user. The Tiny IDE can be used only to view data sources which are located in the `DataXlCalcNet` folder and are located in subfolders beginning with `Data`. The data source examples are organized in a tree structure, which is shown in the right panel (the "folder panel") of the "Tiny Data Viewer" application.

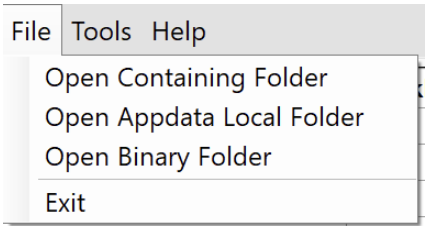
The left panel (the "data panel") of the "Gallery of Plots" application displays the data of the selected file. This panel has 7 tabs: "Text", "Pictures", "SVG", "PDF", "CSV", "SQLiteDb", "Other".

Each file in the `DataXlCalcNet\Data*` folders can be opened in the "Tiny Data Viewer" application by clicking on it. Per application instance, only one file can be opened and displayed at a time (to open an additional file, you need to start a new instance of the application: `Tools -> Tiny Data Viewer (external)`).

1.4.1.1 The menu bar of the application

The Menubar of the "Tiny Data Viewer" application contains the following menus: `File`, `Tools`, and `Help`. Each menu contains a number of items, which are described below.

There are also a button (with green foreground color) in the menu bar: the "Show/Hide" button, which toggles the visibility of the folder panel.



In the `File` menu, two standard items are missing: "New" and "Open".

The "New" item is missing because the application is designed to view existing data, not to create new data.

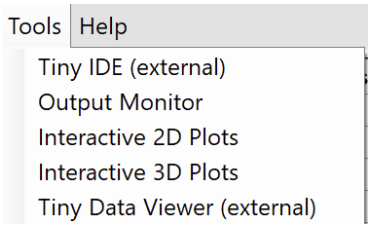
The "Open" item (which would typically open a dialog box with the functionally of the Windows Explorer) is missing because the "Tiny Data Viewer" application is limited to the `DataXlCalcNet` folder. Instead the folder panel allows to navigate through the `DataXlCalcNet` folder and open any file in it.

Renaming or deleting files and folders is possible, but should be done with care, using the Windows Explorer. After these changes, when returning to the Tiny IDE, the tree structure will not be updated automatically, but has to be updated manually by clicking on the appropriate parent folder in the tree structure.

`Open Containing Folder` opens the Windows Explorer in the folder of the current file. This is useful for quickly accessing other files in the same folder, or for deleting files and folders.

`Open Appdata Local Folder` opens the Windows Explorer in the `AppData\Local\XlCalcNetIDE` folder. This is useful for quickly accessing files and folders which are generated by running Python or C# code examples in the Tiny IDE.

`Open Binary Folder` opens the Windows Explorer in the `Bin` subfolder of the `XlCalcNet` installation. This is useful mostly for debugging purposes.



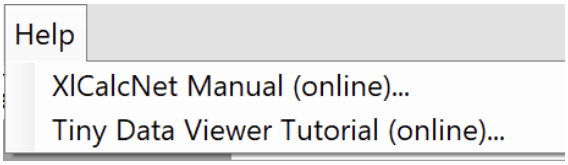
`Tiny IDE (external)` starts the Tiny IDE application, see *here* for details.

`Output Monitor` starts the "Output Monitor" application, see *here* for details.

`Gallery of Plots` starts the "Gallery of Plots" application, see *here* for details.

`Interactive 3D Wpf Plots` starts an additional the Interactive 3D Wpf Plots application, see *here* for details.

`Tiny Data Viewer (external)` starts an additional instance of the Tiny Data Viewer application, see *here* for details.



In the `Help` menu, `XlCalcNet Manual (online)...` displays the start page of the XlCalcNet online manual in a web browser.

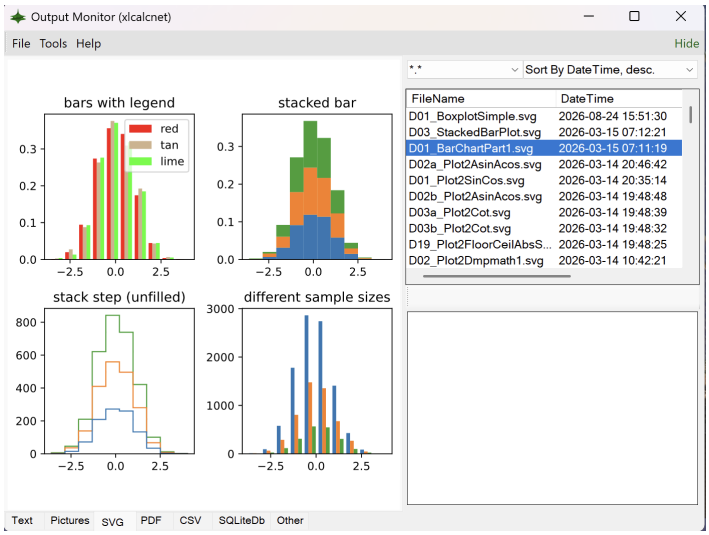
`Tiny Data Viewer Tutorial (online)...` displays the section of the XlCalcNet.online manual which explains the use of the Tiny Data Viewer application in a web browser.

1.4.1.2 Source code

The C# source code for the data viewer can be found here: https://github.com/duhadler/XlCalcNet/tree/master/xlcalcnet/Addin/NET48/Source/DataViewer

1.4.2 The Output Monitor

The "Output Monitor" application is started from the Tiny IDE: in the main menu, click on `Tools -> Output Monitor`. The screenshot below shows an example



The "Output Monitor" application is designed to be used together with spreadsheet functions, when the output is a table or a graphics file, and it it not convenient to incorporate the output into the spreadsheet right away.

The folder which is monitored is `PathToLocalAppDara\\XlCalcNetIDE\OutputMonitor`. Whenever a file changes or is newly created in this folder, the "Output Monitor" application is updated.

The Tiny IDE can be used only to view data which are located in the `OutputMonitor` folder. The files in this folder are organized in a tree structure, which is shown in the right panel (the "folder panel") of the "Output Monitor" application.

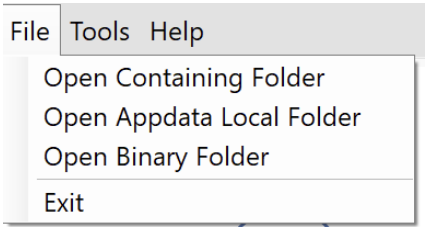
The left panel (the "data panel") of the "Gallery of Plots" application displays the data of the selected file. This panel has 7 tabs: "Text", "Pictures", "SVG", "PDF", "CSV", "SQLiteDb", "Other".

Each file in the `DataXlCalcNet\Data*` folders can be opened in the "Output Monitor" application by clicking on it. Per application instance, only one file can be opened and displayed at a time (to open an additional file, you need to start a new instance of the application: `Tools -> Output Monitor (external)`).

1.4.2.1 The menu bar of the application

The Menubar of the "Output Monitor" application contains the following menus: `File`, `Tools`, and `Help`. Each menu contains a number of items, which are described below.

There are also a button (with green foreground color) in the menu bar: the "Show/Hide" button, which toggles the visibility of the folder panel.



In the `File` menu, two standard items are missing: "New" and "Open".

The "New" item is missing because the application is designed to view existing data, not to create new data.

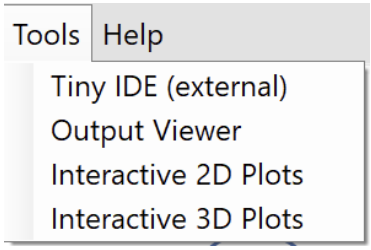
The "Open" item (which would typically open a dialog box with the functionally of the Windows Explorer) is missing because the "Output Monitor" application limited to the `OutputMonitor` folder. Instead the folder panel allows to navigate through the `DataXlCalcNet` folder and open any file in it.

Renaming or deleting files and folders is possible, but should be done with care, using the Windows Explorer. After these changes, when returning to the "Output Monitor" application, the "Output Monitor" application is updated automatically.

`Open Containing Folder` opens the Windows Explorer in the folder of the current file. This is useful for quickly accessing other files in the same folder, or for deleting files.

`Open Appdata Local Folder` opens the Windows Explorer in the `AppData\Local\XlCalcNetIDE` folder. This is useful for quickly accessing files and folders which are generated by running Python or C# code examples in the Tiny IDE.

`Open Binary Folder` opens the Windows Explorer in the `Bin` subfolder of the `XlCalcNet` installation. This is useful mostly for debugging purposes.



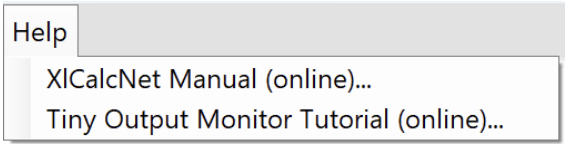
`Tiny IDE` starts the Tiny IDE application, see *here* for details.

`Output Monitor (external)` starts an additional instance of the the "Output Monitor" application, see *here* for details.

`Gallery of Plots` starts the gallery of plots application, see *here* for details.

`Interactive 3D Wpf Plots` starts an additional the Interactive 3D Wpf Plots application, see *here* for details.

`Tiny Data Viewer` starts the Tiny Data Viewer application, see *here* for details.



In the `Help` menu, `XlCalcNet Manual (online)...` displays the start page of the XlCalcNet online manual in a web browser.

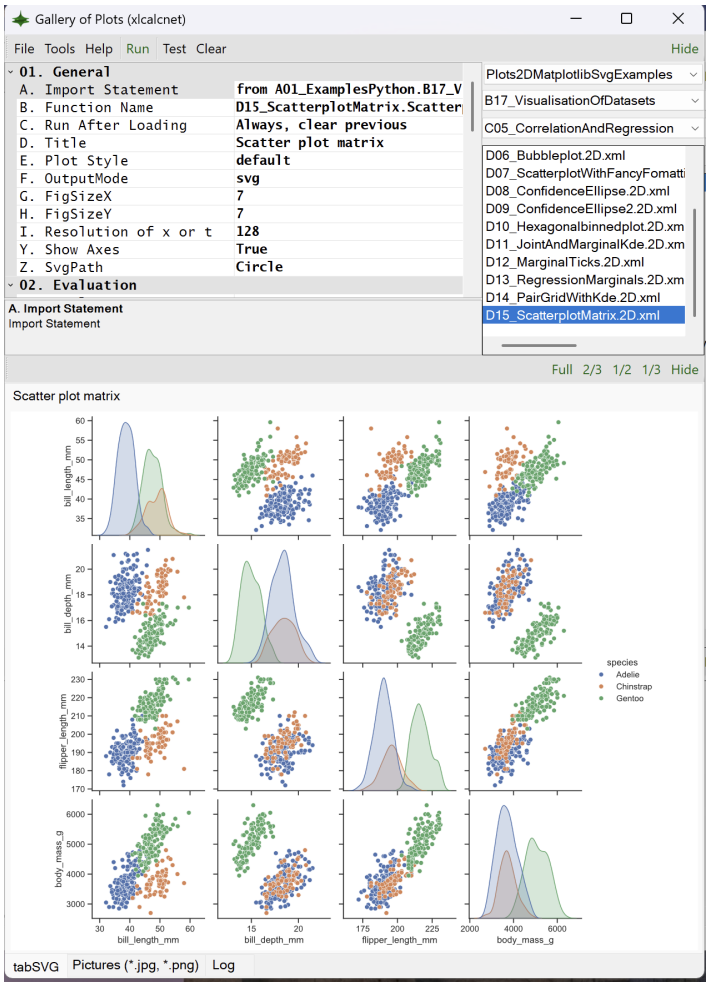
`Tiny Data Viewer Tutorial (online)...` displays the section of the XlCalcNet.online manual which explains the use of the Tiny Data Viewer application in a web browser.

1.4.2.2 Source code

The C# source code for the output monitor can be found here: https://github.com/duhadler/XlCalcNet/tree/master/xlcalcnet/Addin/NET48/Source/OutputMonitor

1.4.3 The Gallery of Plots

The "Gallery of Plots" application is started from the Tiny IDE: in the main menu, click on `Tools -> Gallery of Plots`. The screenshot below shows an example



The "Gallery of Plots" application is designed around the structure of the `DataXlCalcNet` folder, making it easy to navigate and manage existing plot definition examples, as well a new plot definitions written by the user. This application can be used only to edit and run plot definition examples which are located in the `DataXlCalcNet` folder and are located in subfolders beginning with `GalleryOfPlots`. The plot definition examples are organized in a tree structure, which is shown in the top right panel (the "folder panel") of the "Gallery of Plots" application.

The top left panel (the "plot definition editor panel") of the application shows the plot definition of the selected file, which can be edited and run. The plot definition is stored as an *.xml* file, but is edited in a property grid. This allows to structure the definition and to use of drop down boxes to make the definition of the plot easier.

The output of the program is shown in the bottom panel (the "output panel") of the application, which has 3 tabs: the "SVG" tab, the "Pictures" tab, the "Log" tab.

Each file in the `DataXlCalcNet\GalleryOfPlots*` folders can be opened in the application by clicking on it. Per application instance, only one file can be opened, edited and run at a time (to open an additional file, you need to start a new instance of the "Gallery of Plots" application: `Tools -> "Gallery of Plots" application (external)`). The application will load this file into the editor, and the plot definition can be edited and run. To run the plot definition, click on the "Run" button in the main menu. The output is shown in the output panel.

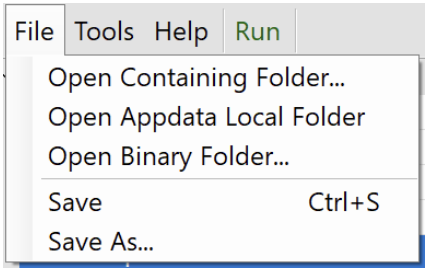
The ordering and naming of the code examples in the subfolder `Plots3DWpfExamples` match the ordering and naming of the corre-

sponding chapters, sections and subsections in this manual, making it easy to find the code example which corresponds to a specific section of the manual. The "section help" feature (`Help -> Section Help`), which is available in the main menu of the "Gallery of Plots" application and opens the corresponding section of this manual in a web browser, depends on this ordering and naming.

1.4.3.1 The menu bar of the application

The Menubar of the "Gallery of Plots" application contains the following menus: `File`, `Tools`, and `Help`. Each menu contains a number of items, which are described below.

There are also two buttons (with green foreground color) in the menu bar: the "Run" button, which runs the code of the current file, and the "Show/Hide" button, which toggles the visibility of the folder panel.



In the `File` menu, two standard items are missing: "New" and "Open".

The "New" item is missing because the Tiny IDE is designed to work within the `DataXlCalcNet` folder, and therefore new files which are not in the current folder should be created in the appropriate subfolders of `DataXlCalcNet`, which often have to be created manually first using the Windows Explorer.

There is, however, a `Save As` item in the file menu, which allows to save the current file under a new name in the current folder. This is useful for creating a copy of an existing file, and using this as a starting point for a new file.

The "Open" item (which would typically open a dialog box with the functionally of the Windows Explorer) is missing because the Tiny IDE is limited to the `DataXlCalcNet` folder. Instead the folder panel allows to navigate through the `DataXlCalcNet` folder and open any file in it.

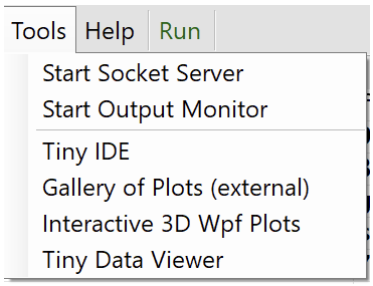
Renaming or deleting files and folders is possible, but should be done with care, using the Windows Explorer, and not using the Tiny IDE. After these changes, when returning to the Tiny IDE, the tree structure will not be updated automatically, but has to be updated manually by clicking on the appropriate parent folder in the tree structure.

`Open Containing Folder` opens the Windows Explorer in the folder of the current file. This is useful for quickly accessing other files in the same folder, or for deleting files and folders.

`Open Appdata Local Folder` opens the Windows Explorer in the `AppData\Local\XlCalcNetIDE` folder. This is useful for quickly accessing files and folders which are generated by running Python or C# code examples in the Tiny IDE.

`Open Binary Folder` opens the Windows Explorer in the `Bin` subfolder of the `XlCalcNet` installation. This is useful mostly for debugging purposes.

`Save` will just save the current file without any further action. `Save As` has been descibed above. `Exit` will close the Tiny IDE.



`Start Socket Server` starts the socket server, see *here* for details.

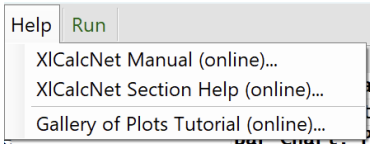
`Start Output Monitor` starts the output monitor application, see *here* for details.

`Tiny IDE` starts the Tiny IDE application, see *here* for details.

`Gallery of Plots` starts the gallery of plots application, see *here* for details.

`Interactive 3D Wpf Plots` starts the Interactive 3D Wpf Plots application, see *here* for details.

`Tiny Data Viewer` starts the Tiny Data Viewer application, see *here* for details.



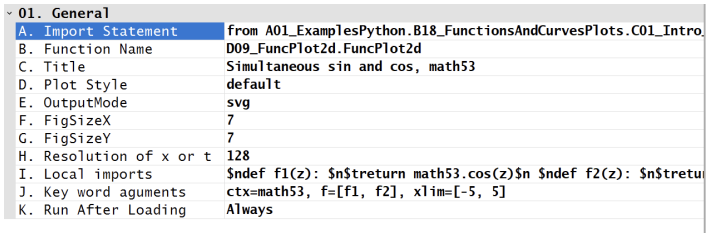
In the `Help` menu, `XlCalcNet Manual (online)...` displays the start page of the XlCalcNet online manual in a web browser.

`XlCalcNet Section Help (online)...` displays the section of the XlCalcNet.online manual which corresponds to the current file in a web browser.

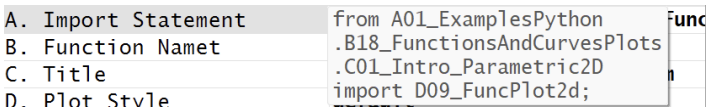
`Interactive 3D plots Tutorial (online)...` displays the section of the XlCalcNet.online manual which explains the use of the Interactive 3D plots application in a web browser.

1.4.3.2 The General section in the edtior property grit

As described above, the plot definition is edited in a property grid:



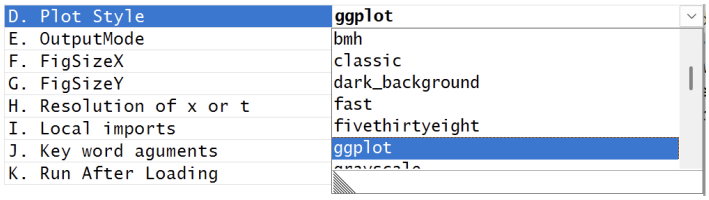
The example above shows the plot definition of the file `\GalleryOfPlotsExamples\B18_FunctionsAndCurvesPlots\C01_Intro_Parametric2D\D09b_SinCosMath53.2D.xml`.



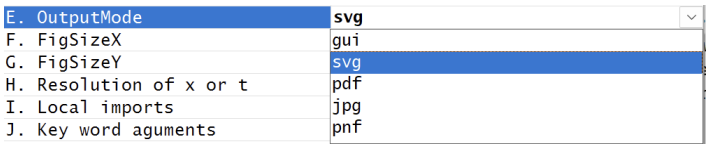
A. Import Statement contains the import statement.

B. Function Name contains the function name.

C. Title contains the function title.



D. PlotStyle contains the plotstyle (see above).

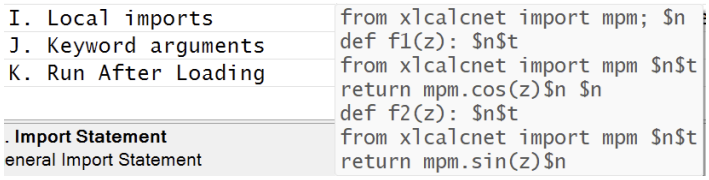


E. OutputMode contains the Output Mode (see above).

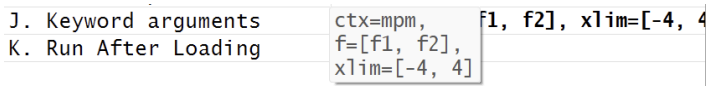
G. FigSizeX contains the size of the figure in x (horizontal) direction.

F. FigSizeY contains the size of the figure in y (vertical) direction.

H. Resolution of x or t contains the resolution of x or t.

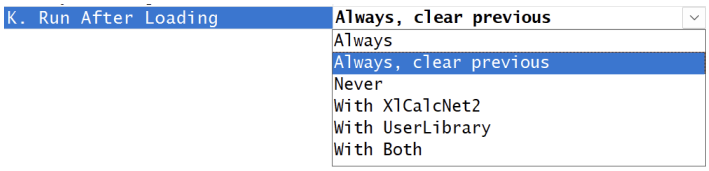


I. Local imports contains the local imports and definitions before the function call.



J. Keyword arguments contains the which passed to function.

Some text



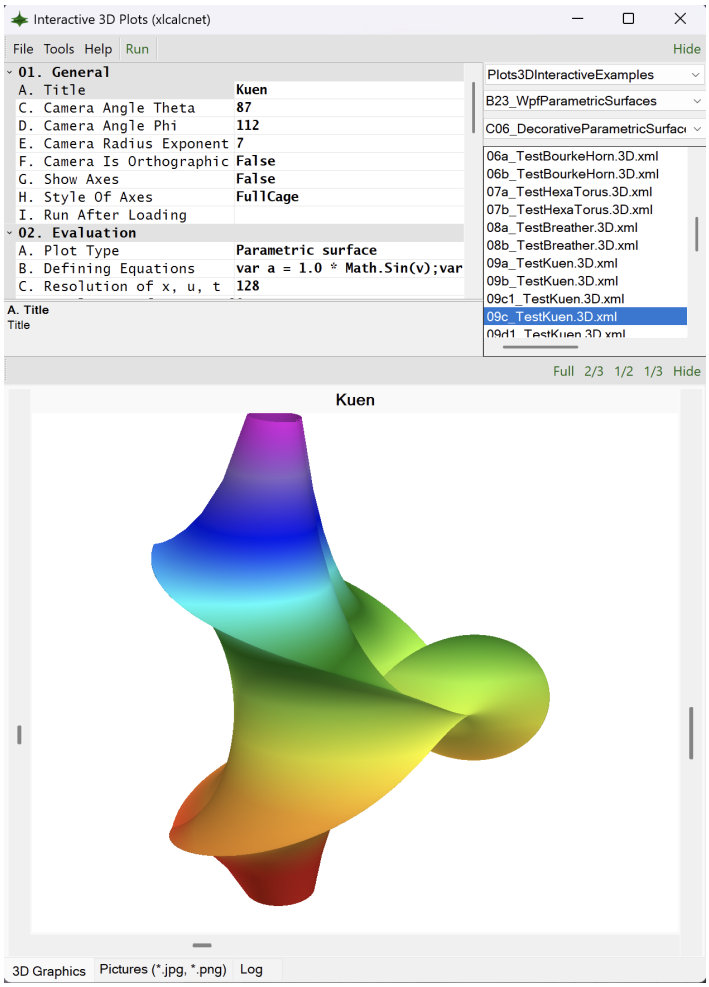
K. Run After loading determines whether and how the plot definition is run after loading (see above).

1.4.3.3 Source code

The C# source code for the gallery of plots can be found here: https://github.com/duhadler/XlCalcNet/tree/master/xlcalcnet/Addin/NET48/Source/TinyPlot2D

1.4.4 Interactive 3D wpf plots

The "Interactive 3D Wpf Plots" application is started from the Tiny IDE: in the main menu, click on `Tools -> Interactive 3D Wpf Plots`. The screenshot below shows an example



The "Interactive 3D Wpf Plots" application is designed around the structure of the `DataXlCalcNet` folder, making it easy to navigate and manage existing 3D plot definition examples, as well a new definitions written by the user. This application can be used only to edit and run 3D plot definition examples which are located in the `DataXlCalcNet` folder and are located in subfolders beginning with `Plots3D`. The code examples are organized in a tree structure, which is shown in the top right panel (the "folder panel") of the application.

The top left panel (the "3D plot definition editor panel") of the application shows the 3D plot definition of the selected file, which can be edited and run. The 3D plot definition is stored as an *.xml* file, but is edited in a property grid. This allows to structure the definition in the sections `0.1 General`, `02. Evaluation`, `03. Reshaping`, `Formatting`, and to use drop down menus to make the definition of the 3D plot easier.

The output of the program is shown in the bottom panel (the "output panel") of the application, which has 3 tabs: the "3D graphics" tab, which displays the interactive 3D plot; the "Pictures" tab, which shows available pictures which can be used as textures; and the "Log" tab, which documents the progress of compiling and running the code containing the "Defining Equations" and the "Expression Evaluator" (and also displays warning and error messages).

Each file in the `DataXlCalcNet\Plots3D*` folders can be opened in the application by clicking on it. Per application instance, only one file can be opened, edited and run at a time (to open an additional file, you need to start a new instance of the application: `Tools -> Interactive 3D Wpf Plots`). The application will load this file into the 3D plot definition editor, and the 3D plot definition can be edited and run. To run the 3D plot definition, click on the "Run" button in the main menu. The output is shown in the output

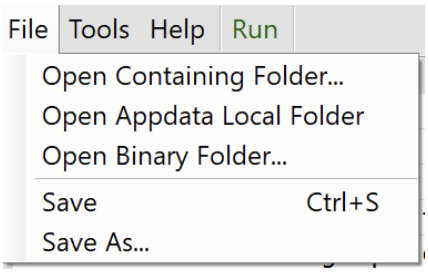
panel.

The ordering and naming of the 3D plot definition examples in the subfolder `Plots3DWpfExamples` match the ordering and naming of the corresponding chapters, sections and subsections in this manual, making it easy to find the 3D plot definition example which corresponds to a specific section of the manual. The "section help" feature (`Help -> Section Help`), which is available in the main menu of the application and opens the corresponding section of this manual in a web browser, depends on this ordering and naming.

1.4.4.1 The menu bar of the application

The Menubar of the "Interactive 3D Wpf Plots" application contains the following menus: `File`, `Tools`, and `Help`. Each menu contains a number of items, which are described below.

There are also two buttons (with green foreground color) in the menu bar: the "Run" button, which runs the code of the current file, and the "Show/Hide" button, which toggles the visibility of the folder panel.



In the `File` menu, two standard items are missing: "New" and "Open".

The "New" item is missing because the Tiny IDE is designed to work within the `DataXlCalcNet` folder, and therefore new files which are not in the current folder should be created in the appropriate subfolders of `DataXlCalcNet`, which often have to be created manually first using the Windows Explorer.

There is, however, a `Save As` item in the file menu, which allows to save the current file under a new name in the current folder. This is useful for creating a copy of an existing file, and using this as a starting point for a new file.

The "Open" item (which would typically open a dialog box with the functionally of the Windows Explorer) is missing because the Tiny IDE is limited to the `DataXlCalcNet` folder. Instead the folder panel allows to navigate through the `DataXlCalcNet` folder and open any file in it.

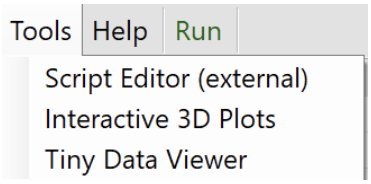
Renaming or deleting files and folders is possible, but should be done with care, using the Windows Explorer, and not using the Tiny IDE. After these changes, when returning to the Tiny IDE, the tree structure will not be updated automatically, but has to be updated manually by clicking on the appropriate parent folder in the tree structure.

`Open Containing Folder` opens the Windows Explorer in the folder of the current file. This is useful for quickly accessing other files in the same folder, or for deleting files and folders.

`Open Appdata Local Folder` opens the Windows Explorer in the `AppData\Local\XlCalcNetIDE` folder. This is useful for quickly accessing files and folders which are generated by running Python or C# code examples in the Tiny IDE.

`Open Binary Folder` opens the Windows Explorer in the `Bin` subfolder of the `XlCalcNet` installation. This is useful mostly for debugging purposes.

`Save` will just save the current file without any further action. `Save As` has been descibed above. `Exit` will close the Tiny IDE.



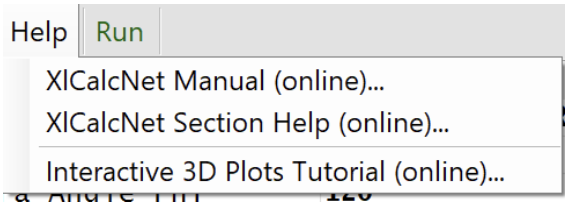
`Tiny IDE` starts the Tiny IDE application, see *here* for details.

`Output Monitor (external)` starts an additional instance of the the "Output Monitor" application, see *here* for details.

`Gallery of Plots` starts the gallery of plots application, see *here* for details.

`Interactive 3D Wpf Plots (external)` starts an additional the Interactive 3D Wpf Plots application, see *here* for details.

`Tiny Data Viewer` starts the Tiny Data Viewer application, see *here* for details.

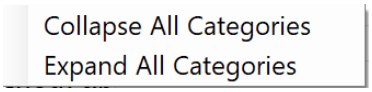


In the `Help` menu, `XlCalcNet Manual (online)...` displays the start page of the XlCalcNet online manual in a web browser.

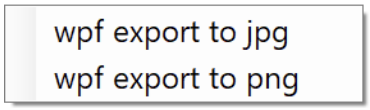
`XlCalcNet Section Help (online)...` displays the section of the XlCalcNet.online manual which corresponds to the current file in a web browser.

`Interactive 3D plots Tutorial (online)...` displays the section of the XlCalcNet.online manual which explains the use of the Interactive 3D plots application in a web browser.

1.4.4.2 The context menus of the 3D plot definition editor



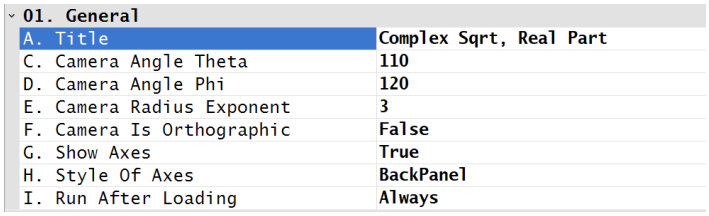
Right-clicking in the 3D plot definition editor opens a context menu, which provides quick access to



Right-clicking in the 3D Graphics tab in the output panel opens a context menu, which provides quick access to

1.4.4.3 The General section in the edtior property grit

The General section in the edtior property grit contains the following items:



A. Title contains the title of the graphics

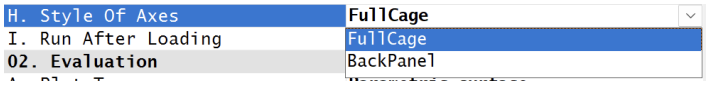
C. Camera Angle Theta contains the camera angle theta.

D. Camera Angle Phi contains the camera angle phi.

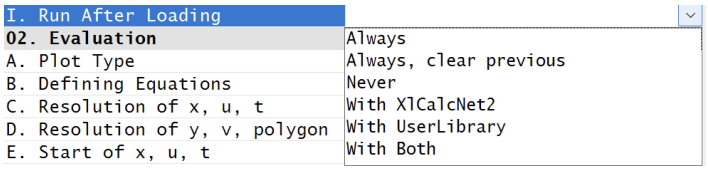
E. Camera Radius Exponent contains the camera radius exponent.

F. Camera Is Orthographic determines if the camera is orthographic or perspective.

G. Show Axes determines if axes are shown in the graphics.



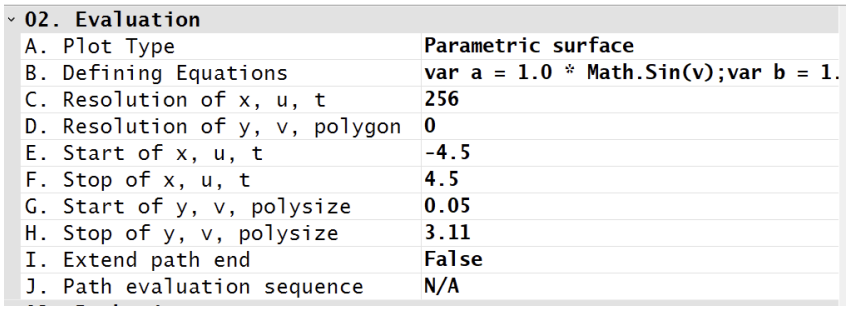
H. Style Of Axes determines the style axes (if any).

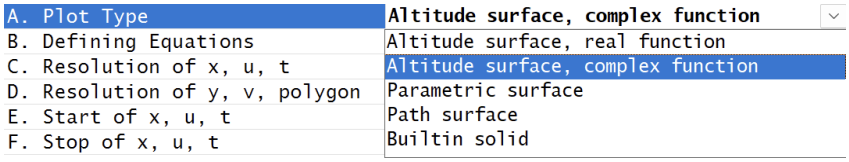


I. Run After Loading determines the action which occurs after loading the plot definition.

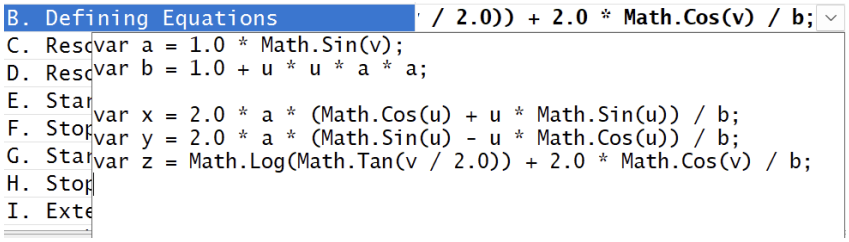
1.4.4.4 The Evaluation section in the edtior property grit

The Evaluation section in the edtior property grit contains the following items:

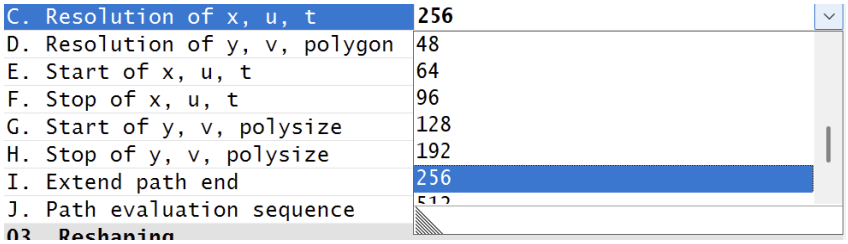




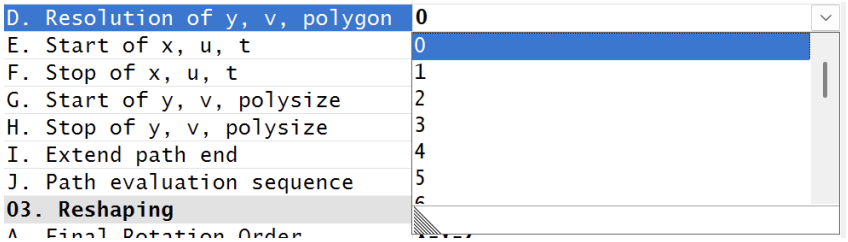
A. Plot Type determines the plot type.



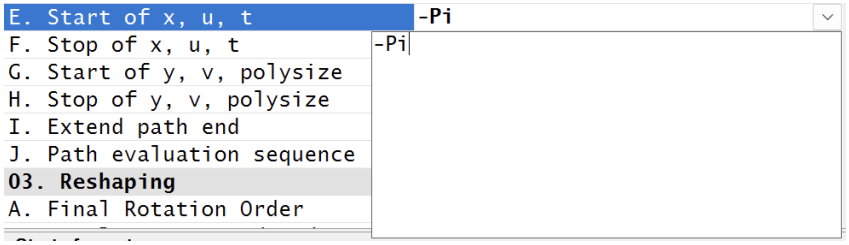
B. Defining equations contains the C# code for the equations which define the graphics.



C. Resolution of x, u, t determines the resolution of the variable, x ,u or t, depending on the plot type.



D. Resolution of y, v, polygon determines the resolution of the variable, y ,v or polygon, depending on the plot type.



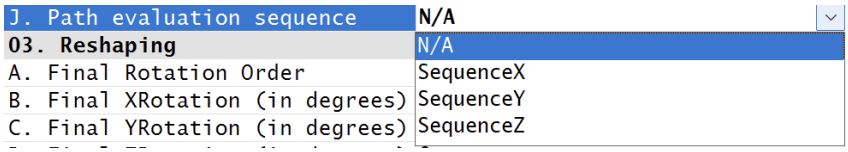
E. Start of x, u, t determines the start of the variable, x ,u or t, depending on the plot type.

F. Stop of x, u, t determines the stop of the variable, x ,u or t, depending on the plot type.

G. Start of y, v, polygon determines the start of the variable, y ,v or polygon, depending on the plot type.

H. Stop of y, v, polygon determines the stop of the variable, y ,v or polygon, depending on the plot type.

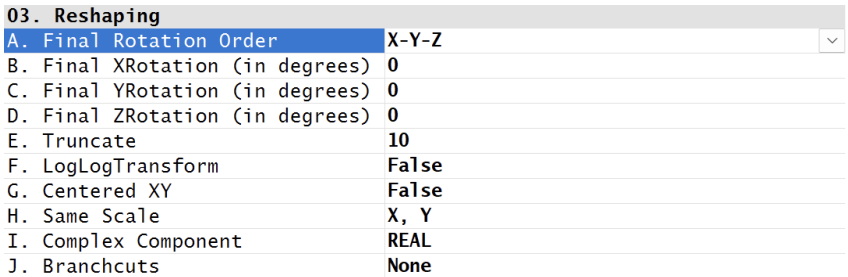
I. Extend path end determines if the path end is extended to close the path. Only relevant for path surfaces.

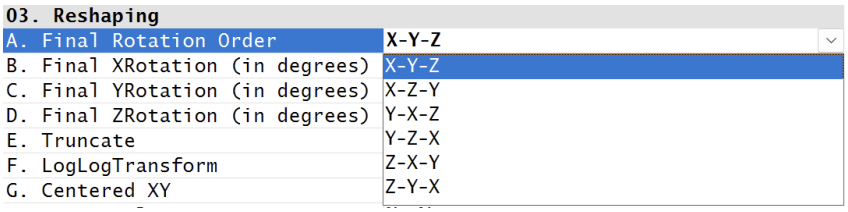


J. Path evaluation sequence determines the path sequence which is used for optimal results. Only relevant for path surfaces.

1.4.4.5 The Reshaping section in the edtior property grit

The Evaluation section in the edtior property grit contains the following items:





A. Final Rotation Order Sets the order for the final rotation (if any).

B. Final XRotation (in degrees) Rotation around the X axis (in degrees).

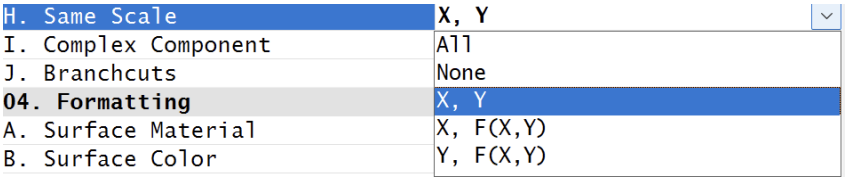
C. Final YRotation (in degrees) Rotation around the Y axis (in degrees).

D. Final ZRotation (in degrees) Rotation around the Z axis (in degrees).

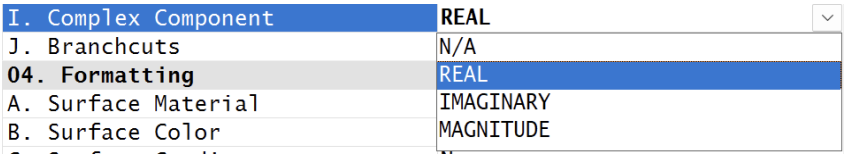
E. Truncate Sets the truncation threshold for the Z axis.

F. LogLogTransform determines if the LogLog transform is applied.

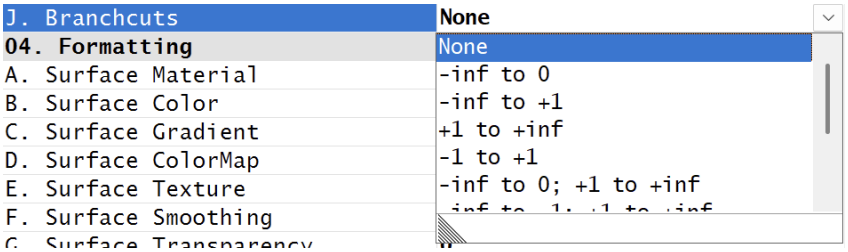
G. Centered XY determines if x,y are centered or not.



H. Same Scale determines which axes are using the same scale.



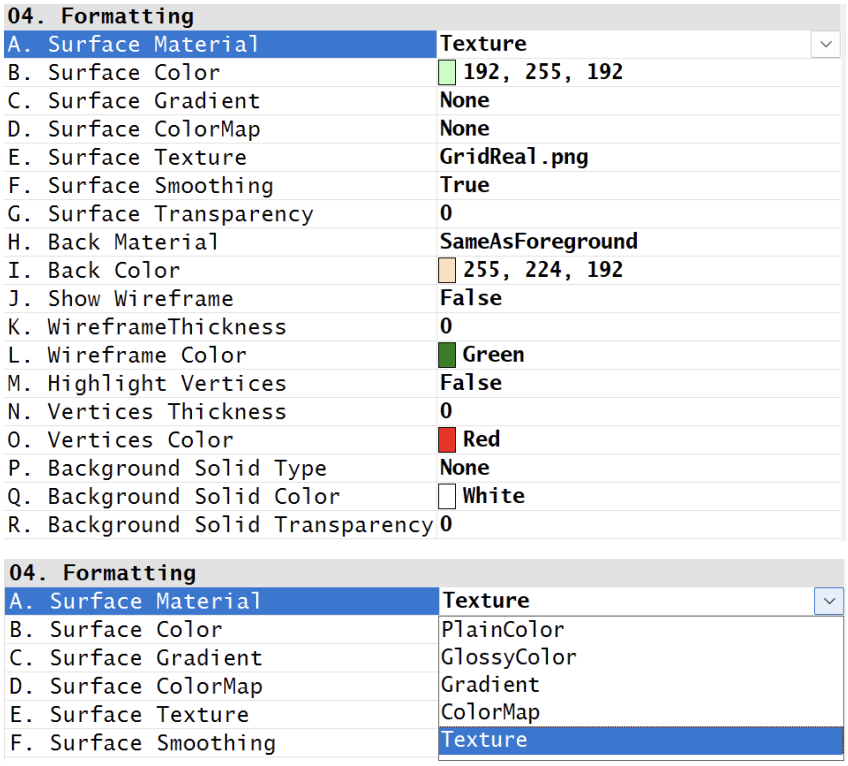
I. Complex Component determines which complex component is used. Only relevant if the plot type is Altitude surface, complex function.



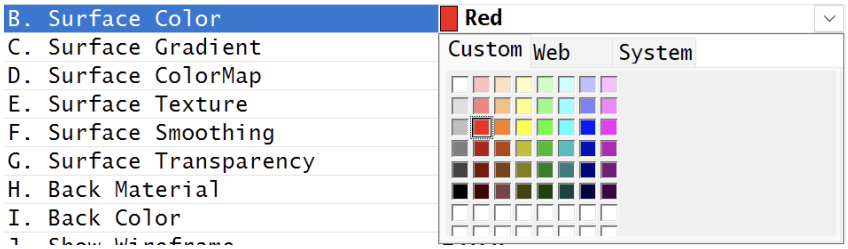
J. Branchcuts determines which brachcuts. Only relevant if the plot type is Altitude surface, complex function.

1.4.4.6 The Formatting section in the edtior property grit

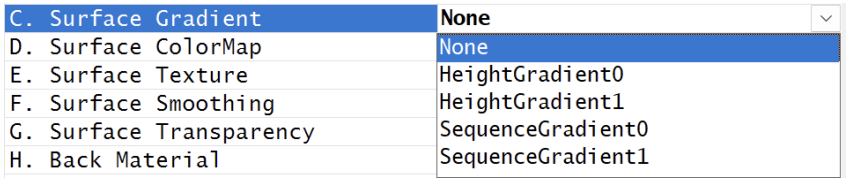
The Formatting section in the edtior property grit contains the following items:



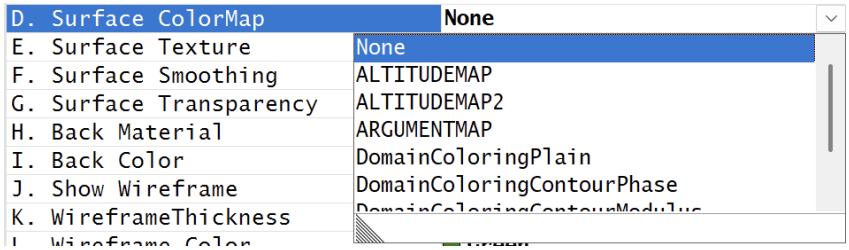
A. Surface Material determines which surface material is used.



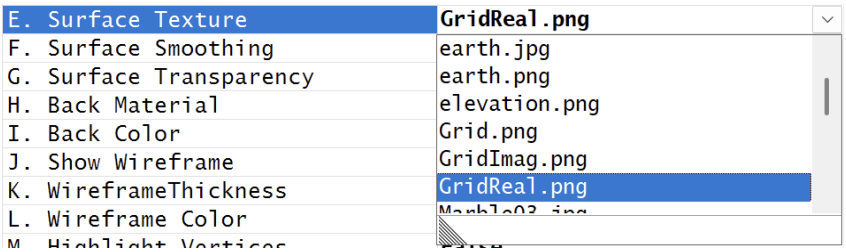
B. Surface Color determines which surface color is used. Note that there are 3 different tabs which can be used to choose the color. Only relevant the surface material is Plain Color or Glossy Color.



C. Surface Gradient determines which surface gradient is used.. Only relevant if the surface material is Gradient.



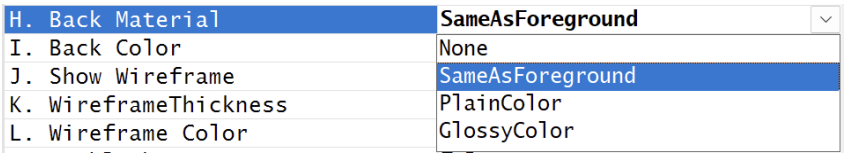
D. Surface ColorMap determines which surface colormap is used.. Only relevant if the surface material is ColorMap.



E. Surface Texture determines which texture is used.. Only relevant if the surface material is Texture.

F. Surface Smoothing determines if surface smoothing is applied.

G. Surface Transparency determines the amount of surface transparency (from o to 255).



H. Back Material determines the background material.

I. Back Color determines the background color.

J. Show Wireframe determines if a wireframe is shown.

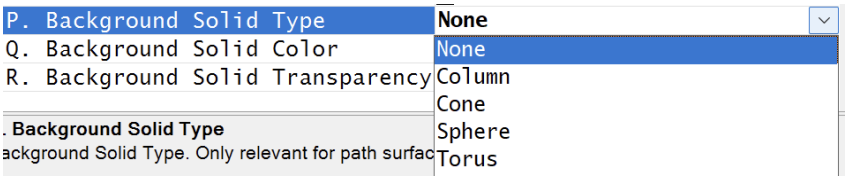
K. Wireframe Thickness determines the wireframe thickness.

L. Wireframe Color determines the wireframe color.

M. Highlight Vertices determines if vertices are highlighted.

N. Vertices Thickness determines the thickness of the vertices.

O. Vertices Color determines the color of the vertices.



P. Background Solid Type determines the type of the background, if any.

Q. Background Solid color determines the color of the background, if any.

R. Background Solid Transparency determines the amount of surface transparency (from o to 255).

1.4.4.7 Source code

The Python source code for starting the IDE can be found here: https://github.com/duhadler/XlCalcNet/blob/master/xlcalcnet/ShowEditor.py

The C# source code for the gallery of plots can be found here: https://github.com/duhadler/XlCalcNet/tree/master/xlcalcnet/Addin/NET48/Source/TinyPlot3D

Much of the C# code of this application is based on Stephens [507].

1.4.5 Functions related to folders

There are several functions related to folders

gui.**get_local_appdata**()

Return the current user's local Application Data folder

```
>>> from xlcalcnet import gui
>>> gui.get_local_appdata()
```

gui.**get_local_appdata_xlcalcnet**()

Return the current user's local AppData/XlCalcNetIDE folder

```
>>> from xlcalcnet import gui
>>> gui.get_local_appdata_xlcalcnet()
```

gui.**get_my_documents**()

Return the current user's local AppData/XlCalcNetIDE folder

```
>>> from xlcalcnet import gui
>>> gui.get_my_documents()
```

1.4.6 Information about installation status of supporting python packages

gui.**info**()

Support for Matplotlib output in a separate process

```
>>> from xlcalcnet import gui
>>> gui.info()
```

gui.**has_gpm**()

Returns True if gmpy2 is installed

```
>>> from xlcalcnet import gui
>>> gui.has_gpm()
```

gui.**has_apm**()

Returns True if python-flint is installed

```
>>> from xlcalcnet import gui
>>> gui.has_apm()
```

gui.**has_xlcalcnet2**()

Returns True if xlcalcnet2 is installed

```
>>> from xlcalcnet import gui
>>> gui.has_xlcalcnet2()
```

1.4.7 Information about context lists, and setting global precision

property gui.**ctxlistreal**

Returns a list of all available numerical contexts supporting real data types

```
>>> from xlcalcnet import gui
>>> gui.ctxlistreal
```

property gui.**ctxlistcplx**

Returns a list of all available numerical contexts supporting complex data types

```
>>> from xlcalcnet import gui
>>> gui.ctxlistcomplex
```

gui.**setdps**(*dps*)

Sets the decimal precision for all multiprecision data types

```
>>> from xlcalcnet import gui
>>> dps = 50
>>> gui.setdps(dps)
```

1.4.8 Support for running interactive Matplotlib output in a separate process

There is support for Matplotlib output in a separate process

See also: https://matplotlib.org/stable/users/explain/figure/interactive.html#default-ui

property gui.**plot**(*fig*, *file*, *fname*)

Support for Matplotlib output in a separate process

```
>>> from xlcalcnet import gui
>>> gui.plot(fig, file, fname)
```

1.5 Mathematical functions based on Mpmath, Gmpy2 and Python-Flint (only Python)

1.5.1 Overview

1.5.1.1 Contexts

The following group of contexts are available in Python only:

- Context group `ctx_pm`: this context group includes `fpm` (see *fpm*), `mpm` (see *mpm*), `dpm` (see *dpm*), `ipm` (see *ipm*), `gpm` (see *gpm*), `apm` (see *apm*). The `gpm` context is only available if Gmpy2 is installed, and the `apm` context is only available if Python-FLINT is installed.

XlCalcNet provides the following contexts from mpmath:

- Double-precision binary floating point arithmetic using Python's builtin `float` and `complex` types (`fp`)
- Arbitrary-precision binary floating point arithmetic (`mp`)
- Arbitrary-precision binary interval arithmetic (`iv`)

and in addition

- Arbitrary-precision decimal arithmetic (`dp`)
- Arbitrary-precision binary floating point arithmetic based on gmpy2 (`gp`): requires gmpy2
- Arbitrary-precision ball arithmetic based on ARB (`ap`): requires xlcalcnet libraries

The implementation of contexts in xlcalcnet extents and sometimes modifies the features of the contexts provided by mpmath; in this manual, changes to features already existing in mpmath will be pointed out explicitly.

By and large, xlcalcnet tries to be compatible with mpmath conventions as much as possible. The main difference is that in xlcalcnet the context must always explicitly be stated, whereas in mpmath the `mp` context is assumed as the default if the context is missing. In mpmath, we can write:

```
>>> from xlcalcnet import *
>>> sqrt(2)
mpf('1.4142135623730951')
```

This does not work in xlcalcnet, where also the `mp` context has to be given explicitly:

```
>>> from xlcalcnet import mp
>>> mp.sqrt(2)
mpf('1.4142135623730951')
```

The need to import xlcalcnet and mpmath into the same module should rarely arise (importing them separately in different modules of the same project is of course fine). If both are imported, care should be taken that the imported components do not shadow each other, e.g.:

```
>>> from xlcalcnet import mp
>>> from xlcalcnet.mpmath import mp as mpm   # importing the mpmath version of xlcalcnet

>>> mp.sqrt(2) # calling xlcalcnet
mpf('1.4142135623730951')
>>> mpm.sqrt(2) # calling mpmath
mpf('1.4142135623730951')
```

1.5.1.2 Conversion of sclars

This function converts scalars into each other

`ctx.t`(*x*, *strings=True*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Converts *x* to an `ctx.mpf` or `ctx.mpc`. If *x* is of type `ctx.mpf`, `ctx.mpc`, `int`, `float`, `complex`, the conversion will be performed losslessly, except in the following cases:

- conversion of a double to a decimal: cutoff at 14 digits
- conversion of an int to a mpfr: cutoff at current precision

If *x* is a string, the result will be rounded to the present working precision. Strings representing fractions or complex numbers are permitted.

```
>>> from xlcalcnet import fpm, mpm, ipm, dec, gmp, apm; ctxall = [fpm, mpm, ipm, dec, gmp, apm]
>>> for ctx in ctxall:
>>> .... print(ctx.name)
>>> .... ctx.dps = 10; print([ctx.t(3.5), ctx.t(2+3j)])
>>> .... ctx.dps = 10; print([ctx.t('3.1'), ctx.t('3.1 + 4.6j')])
fpm
[3.5, (2+3j)]
[3.1, (3.1+4.6j)]

mpm
[mpf('3.5'), mpc(real='2.0', imag='3.0')]
[mpf('3.100000000006'), mpc(real='3.100000000006', imag='4.599999999977')]

ipm
[mpi('3.5', '3.5'), iv.mpc(mpi('2.0', '2.0'), mpi('3.0', '3.0'))]
[mpi('3.099999999977', '3.100000000006'),
iv.mpc(mpi('3.099999999977', '3.100000000006'), mpi('4.599999999977', '4.600000000035'))]

dec
:cite:t:`Decimal('3.5'), DecCplx('2 + 3.0j')]
:cite:t:`Decimal('3.1'), DecCplx('3.1 + 4.6j')]

gmp
[mpfr('3.5',37), mpc('2.0+3.0j',(37,37))]
[mpfr('3.100000000006',37), mpc('3.100000000006+4.599999999977j',(37,37))]

apm
[arb('3.50'), acb('2.00 + 3.00j')]
[arb('[3.09999999998 +/- 3.24e-11]'),
acb('[3.09999999998 +/- 3.24e-11] + [4.59999999998 +/- 6.15e-11]j')]
```

1.5.1.3 Precision in bits and digits

`ctx.prec` holds the current precision (in bits):

The default precision (in bits) for all contexts after starting xlcalcnet is `ctx.prec = 53`.

```
>>> fp.prec, mp.prec, iv.prec, dp.prec, gp.prec, ap.prec
(53, 53, 53, 53, 53, 53)
```

`ctx.dps` holds the current decimal precision (in digits):

The default decimal precision (in digits) for all contexts after starting xlcalcnet is `ctx.dps = 15`.

```
>>> fp.dps, mp.dps, iv.dps, dp.dps, gp.dps, ap.dps
(15, 15, 15, 15, 15, 15)
```

Like mpmath, xlcalcnet expects every devision of a *normal* number by zero to raise a `DivisionByZero`, and not to return `+inf` or `-inf`. This is the default behaviour for the `fp`, `mp`, `iv` and `dp` contexts anyway, and has been changed to follow this convention for the `gp` and `ap` context.

A number of algorithms use this exception to trigger a temporary increase of precision.

1.5.2 Double-precision arithmetic: `fpm`

The Python module `fpm` provides support for real and complex floating point numbers in double precision (see https://en.wikipedia.org/wiki/Double-precision_floating-point_format). The corresponding real and complex data types, `float` and `complex`, are implemented in hardware (and are therefore quite fast).

Note: automatic conversion from `Double` in .Net Framework to `float`

Note: no conversion from `Complex` in .Net Framework to `complex` in Python. Explain workarounds.

1.5.2.1 Examples for `fpm`, real input

General test code for Python can be found here

```
import math
from xlcalcnet import math53
from decimal import Decimal
from fractions import Fraction
i = 232945639845394856394563936482734638475398457398457 3
```

```
def main_tests():
    general_assignments()
    functions_with_argument_conversion()
    arithmetic_operators_with_math53()
```

General test code can be found here

1.5.4.3 Implementation in Python

The Python source code for this module can be found here: ctx_ipm.py.

1.5.5 Decimal floating-point in arbitrary-precision with limited exponent: dpm

The Python module dpm provides support for real and complex decimal floating-point in arbitrary-precision with limited exponent. The corresponding real and complex data types, float and complex, are implemented in software.

Additional contexts are used in xlcalcnet to implement its functions for the mpmath data types, and the Decimal data type, which is part of Python.

Both real numbers (mpf) and complex numbers (mpc) are implemented.

In CPython, the decimal module provides support for fast correctly-rounded decimal floating point arithmetic. See https://docs.python.org/3/library/decimal.html for a decription of the Decimal data type.

The decimal module includes only a few transcendental functions: sqrt, log, exp.

The dec context gives access to many more:

1.5.5.3 Implementation in Python

The Python source code for this module can be found here: ctx_dpm.py.

1.5.6 Rational numbers: qpm

The qpm data type is mostly useful in the context of linear algebra, where it can provide exact results.

Only real numbers (mpf) are implemented.

The internal representation dependes on what else is installed on the system:

If apm is available, the fmpq data type is used; otherwise, if gpm is available, the mpq data type is used; otherwise, Python's built in Fraction data type is used.

In CPython, the fractions module provides support for rational number arithmetic. See https://docs.python.org/3/library/fractions.html for a decription of the Fraction data type.

1.5.6.1 Examples for qpm, real input

General test code for Python can be found here

```
import math
from xlcalcnet import math53
from decimal import Decimal
from fractions import Fraction
i = 232945639845394856394563936482734638475398457398457 3
```

1.5.6.2 Implementation in Python

The Python source code for this module can be found here: ctx_dpm.py.

1.5.7 Binary floating-point in arbitrary-precision with limited exponent: gpm

The Python module `gpm` provides support for real and complex Binary floating-point in arbitrary-precision with limited exponent. The corresponding real and complex data types, `float` and `complex`, are implemented in software.

gmpy2 is a C-coded Python extension module that supports multiple-precision arithmetic.

https://gmpy2.readthedocs.io/en/latest/

Assuming that the Python batch files have been installed as described *here*, gmpy2 can be installed by double-clicking on the batch file `A11installgmpy2.bat` in the `C:\Python313` folder.

1.5.7.1 Examples for gpm, real input

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D08b_ApmCplx.py.

1.5.8.3 Implementation in Python

The Python source code for this module can be found here: ctx_apm.py.

1.5.9 Numpy support for multiprecision data types: `npm`

1.5.9.1 Overview

Numpy supports general objects as elements, and this can be used to use numpy functions for the above data types.

1.6 Mathematical functions in fixed precision (C#, can be called from Python)

1.6.1 C# based context groups

Various additional numerical contexts support C# and Python. It is convenient to divide them into groups to make referencing them per function description more efficient.

The following groups of contexts are available:

1.6.1.1 Context group `ctx53`

This context group includes `math53` and `cmath53` (see *math53/cmath53*). Almost all functions are from the DAMath library, with a few functions from Boost Math, Scipy, Julia and other libraries available on Github.

1.6.1.2 Context group `ctxcpp`

This context group includes contexts which contain functions of the C++ standard library, the Eigen library, and functions which can easily be derived from them. They include contexts in fixed precision: `sreal` and `scplx` (see *sreal/scplx*), `dreal` and `dcplx` (see *dreal/dcplx*), `ereal` and `ecplx` (see *ereal/ecplx*), `qreal` and `qcplx` (see *qreal/cplx*), `oreal` and `ocplx` (see *oreal/ocplx*), ; and contexts in arbitrary precision, which are part of XlCalcNet2 (which hence needs to be installed): `mreal` and `mcplx` (see *mreal/mcplx*).

1.6.1.3 Context group `ctxboost`

This context group includes contexts which contain functions of the the Boost Math/Multiprecision/Odeint libraries, and functions which can easily be derived from them. They include contexts in fixed precision: `sreal` (see *sreal*), `dreal` (see *dreal*), `ereal` (see *ereal*), `qreal` (see *qreal*), `oreal` (see *oreal*), ; and one context in arbitrary precision, which is part of XlCalcNet2 (which hence needs to be installed): `mreal` (see *mreal*).

1.6.1.4 Context group `ctxflint`

This context group includes contexts which contain functions of the Flint 3.4 library, the Eigen library, and functions which can easily be derived from them. These are contexts in fixed and in arbitrary precision, which are part of XlCalcNet2 (which hence needs to be installed). They include `sflint` and `sflintc` (see *sflint/sflintc*), `dflint` and `dflintc` (see *dflint/dflintc*), `eflint` and `eflintc` (see *eflint/eflintc*), `qflint` and `qflintc` (see *qflint/qflint*), `oflint` and `oflintc` (see *oflint/oflintc*), `mflint` and `mflintc` (see *mflint/mflintc*), `aflint` and `aflintc` (see *aflint/aflint*).

1.6.2 Scalar functions with Double and Complex: math53 and cmath53

The C# modules math53 and cmath53 provide support for real and complex floating point numbers in double precision (see https://en.wikipedia.org/wiki/Double-precision_floating-point_format). The corresponding real and complex data types, Double and Complex, are implemented in hardware and are part of .Net Framework (and are therefore quite fast).

Note: automatic conversion from Double in .Net Framework to float

Note: no conversion from Complex in .Net Framework to complex in Python. Explain workarounds.

DAMath library.

1.6.2.1 Examples in C#, math53

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some math53 functions");
    SrealTest0();
    SrealTest1();
}
```

General test code for C# can be found here

```
public static void Math53Test0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "ScplxTest0"  + "\"" + ">");

    var a = cmath53.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = cmath53.abs(a);
    Console.WriteLine("res1 = cmath53.abs(a): {0}", res1);

    var res2 = cmath53.exp(a);
    Console.WriteLine("res2 = cmath53.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

General test code for C# can be found here

```
public static void Math53Test1()
{
    Console.WriteLine("<H1 Title=" + "\"" + "ScplxTest1"  + "\"" + ">");

    var a = cmath53.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = cmath53.asin(a);
    Console.WriteLine("res1 = cmath53.asin(a) {0}", res1);

    var res2 = cmath53.sin(a);
    Console.WriteLine("res2 = cmath53.sin(a) {0}", res2);

    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the DataXlCalcNet repository or in the corresponding local DataXlCalcNet folder in the file D02a_math53.cs.

1.6.2.2 Examples in C#, cmath53

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some math53 functions");
    SrealTest0();
    SrealTest1();
}
```

General test code for C# can be found here

```
public static void ScplxTest0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "ScplxTest0"  + "\"" + ">");

    var a = cmath53.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = cmath53.abs(a);
    Console.WriteLine("res1 = cmath53.abs(a): {0}", res1);

    var res2 = cmath53.exp(a);
    Console.WriteLine("res2 = cmath53.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

General test code for C# can be found here

```
public static void ScplxTest1()
{
    Console.WriteLine("<H1 Title=" + "\"" + "ScplxTest1"  + "\"" + ">");

    var a = cmath53.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = cmath53.asin(a);
    Console.WriteLine("res1 = cmath53.asin(a) {0}", res1);

    var res2 = cmath53.sin(a);
    Console.WriteLine("res2 = cmath53.sin(a) {0}", res2);

    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the DataXlCalcNet repository or in the corresponding local DataXlCalcNet folder in the file D02b_Cmath53.cs.

1.6.2.3 Examples in Python, `math53`

General test code for Python can be found here

```
import math
from xlcalcnet import math53
from decimal import Decimal
from fractions import Fraction
i = 232945639845394856394563936482734638475398457398457 3984573

    print('</H1>')
```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D02b_Cmath53.py.

1.6.2.5 Notes regarding the implementation in C# and C++

The C# source code for the module `math53` can be found here: ctx.cs.

The C# source code for the module `cmath53` can be found here: cmath53.cs.

The Pascal source code which is called from `ctx.cs` and `cmath53.cs` can be found here: libwe64d.pas.

The C++ source code which is called from `ctx.cs` and `cmath53.cs` can be found here: XSF.cpp.

The C# source code (transcribed from the Julia project) which is called from `ctx.cs` and `cmath53.cs` can be found here: fromjulia.cs.

1.6.3 Binary floating point, single precision: `sreal` and `scplx`

The C# modules `sreal` and `scplx` provide support for real and complex floating point numbers in single precision (see https://en.wikipedia.org/wiki/Single-precision_floating-point_format). The corresponding real data type, `Single`, is implemented in hardware and is part of .Net Framework (and is therefore quite fast), the corresponding complex data type, `SingleC`, is also implemented in hardware, but has been added as an object in XlCalcNet (and has therefore the overhead of objects).

The C# modules `sreal` and `scplx` fully support Boost.Math and Eigen.

TODO: python code showing larget, lowest, machine epsilon etc.

1.6.3.1 Examples in C#, `sreal`

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some sreal functions");
    SrealTest0();
    SrealTest1();
}
```

General test code for C# can be found here

```
public static void ScplxTest0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "ScplxTest0"  + "\"" + ">");

    var a = scplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = scplx.abs(a);
    Console.WriteLine("res1 = scplx.abs(a): {0}", res1);

    var res2 = scplx.exp(a);
    Console.WriteLine("res2 = scplx.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

General test code for C# can be found here

```
public static void ScplxTest1()
{
    Console.WriteLine("<H1 Title=" + "\"" + "ScplxTest1"  + "\"" + ">");

    var a = scplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = scplx.asin(a);
    Console.WriteLine("res1 = scplx.asin(a) {0}", res1);

    var res2 = scplx.sin(a);
    Console.WriteLine("res2 = scplx.sin(a) {0}", res2);

    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the DataXlCalcNet repository or in the corresponding local DataXlCalcNet folder in the file D02a_Sreal.cs.

1.6.3.2 Examples in C#, scplx

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some sreal functions");
    SrealTest0();
    SrealTest1();
}
```

General test code for C# can be found here

```
public static void ScplxTest0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "ScplxTest0"  + "\"" + ">");

    var a = scplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = scplx.abs(a);
    Console.WriteLine("res1 = scplx.abs(a): {0}", res1);

    var res2 = scplx.exp(a);
    Console.WriteLine("res2 = scplx.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

General test code for C# can be found here

```
public static void ScplxTest1()
{
    Console.WriteLine("<H1 Title=" + "\"" + "ScplxTest1"  + "\"" + ">");

    var a = scplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = scplx.asin(a);
    Console.WriteLine("res1 = scplx.asin(a) {0}", res1);

    var res2 = scplx.sin(a);
    Console.WriteLine("res2 = scplx.sin(a) {0}", res2);

    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the DataXlCalcNet repository or in the corresponding local DataXlCalcNet folder in the file D03b_Scplx.cs.

1.6.3.3 Examples in Python, sreal

General test code for Python can be found here

```
import math

```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D03b_SCplx.py.

1.6.3.5 Notes regarding the implementation in C# and C++

The C# source code for the module `sreal` can be found here: sreal.cs.

The C# source code for the module `scplx` can be found here: scplx.cs.

The C++ source code supporting scalars in general which is called from `sreal.cs` and `scplx.cs` can be found here: UseSReal.cpp.

The C++ source code which interacts directly with Boost can be found here: BoostSReal.cpp.

The C++ source code supporting Eigen which is called from `sreal.cs` and `scplx.cs` can be found here: UseEigenSReal.cpp.

The C++ source code which interacts directly with Eigen can be found in the folder: BoostEigenMath.cpp.

1.6.4 Binary floating point, double precision: `dreal` and `dcplx`

The C# modules `dreal` and `dcplx` provide support for real and complex floating point numbers in double precision (see https://en.wikipedia.org/wiki/Double-precision_floating-point_format). The corresponding real and complex data types, `Double` and `Complex`, are implemented in hardware and are part of .Net Framework (and are therefore quite fast).

The C# modules `dreal` and `dcplx` fully support Boost.Math and Eigen.

Note: automatic conversion from `Double` in .Net Framework to `float`

Note: no conversion from `Complex` in .Net Framework to `complex` in Python. Explain workarounds.

Note: issues with multiplication scalar * matrix in complex

1.6.4.1 Examples in C#, `dreal`

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some dreal functions");
    DrealTest0();
    DrealTest1();
}
```

General test code for C# can be found here

```
public static void DcplxTest0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "DcplxTest0"  + "\"" + ">");

    var a = dcplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = dcplx.abs(a);
    Console.WriteLine("res1 = dcplx.abs(a): {0}", res1);

    var res2 = dcplx.exp(a);
    Console.WriteLine("res2 = dcplx.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

General test code for C# can be found here

```
public static void DcplxTest1()
{
    Console.WriteLine("<H1 Title=" + "\"" + "DcplxTest1"  + "\"" + ">");

    var a = dcplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = dcplx.asin(a);
    Console.WriteLine("res1 = dcplx.asin(a) {0}", res1);

    var res2 = dcplx.sin(a);
    Console.WriteLine("res2 = dcplx.sin(a) {0}", res2);
```

(continues on next page)

(continued from previous page)

```
    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D04a_Dreal.cs.

1.6.4.2 Examples in C#, `dcplx`

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some dreal functions");
    DrealTest0();
    DrealTest1();
}
```

General test code for C# can be found here

```
public static void DcplxTest0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "DcplxTest0"  + "\"" + ">");

    var a = dcplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = dcplx.abs(a);
    Console.WriteLine("res1 = dcplx.abs(a): {0}", res1);

    var res2 = dcplx.exp(a);
    Console.WriteLine("res2 = dcplx.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

General test code for C# can be found here

```
public static void DcplxTest1()
{
    Console.WriteLine("<H1 Title=" + "\"" + "DcplxTest1"  + "\"" + ">");

    var a = dcplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = dcplx.asin(a);
    Console.WriteLine("res1 = dcplx.asin(a) {0}", res1);

    var res2 = dcplx.sin(a);
    Console.WriteLine("res2 = dcplx.sin(a) {0}", res2);

    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D04b_Dcplx.cs.

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D04b_DCplx.py.

1.6.4.5 Notes regarding the implementation in C# and C++

The C# source code for the module `dreal` can be found here: dreal.cs.

The C# source code for the module `dcplx` can be found here: dcplx.cs.

The C++ source code supporting scalars in general which is called from `dreal.cs` and `dcplx.cs` can be found here: UseFReal.cpp.

The C++ source code which interacts directly with Boost can be found here: BoostSReal.cpp, and BoostDouble.cpp.

The C++ source code supporting Eigen which is called from `dreal.cs` and `dcplx.cs` can be found here: UseEigenFReal.cpp.

The C++ source code which interacts directly with Eigen can be found in the folder: BoostEigenMath.cpp.

1.6.5 Binary floating point, extended precision: `ereal` and `ecplx`

The C# modules `ereal` and `ecplx` provide support for real and complex floating point numbers in extended precision (see https://en.wikipedia.org/wiki/Extended_precision). The corresponding real and complex data types, `Extended` and `ExtendedC`, have been added as objects in XlCalcNet (and have therefore the overhead of objects). They are, however, implemented in hardware, and are supported as native types in C++ (when using GCC). This means that the routines in extended precision provided in Boost and Eigen are much faster than the corresponding routines in quadruple precision.

The C# modules `ereal` and `ecplx` fully support Boost.Math and Eigen.

1.6.5.1 Examples in C#, `ereal`

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some ereal functions");
    ErealTest0();
    ErealTest1();
}
```

General test code for C# can be found here

```
public static void EcplxTest0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "EcplxTest0"  + "\"" + ">");

    var a = ecplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = ecplx.abs(a);
    Console.WriteLine("res1 = ecplx.abs(a): {0}", res1);

    var res2 = ecplx.exp(a);
    Console.WriteLine("res2 = ecplx.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

General test code for C# can be found here

```
public static void EcplxTest1()
{
    Console.WriteLine("<H1 Title=" + "\"" + "EcplxTest1"  + "\"" + ">");

    var a = ecplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = ecplx.asin(a);
    Console.WriteLine("res1 = ecplx.asin(a) {0}", res1);

    var res2 = ecplx.sin(a);
    Console.WriteLine("res2 = ecplx.sin(a) {0}", res2);

    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the DataXlCalcNet repository or in the corresponding local DataXlCalcNet folder in the file D05a_Ereal.cs.

1.6.5.2 Examples in C#, ecplx

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some ereal functions");
    ErealTest0();
    ErealTest1();
}
```

General test code for C# can be found here

```
public static void EcplxTest0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "EcplxTest0"  + "\"" + ">");

    var a = ecplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = ecplx.abs(a);
    Console.WriteLine("res1 = ecplx.abs(a): {0}", res1);

    var res2 = ecplx.exp(a);
    Console.WriteLine("res2 = ecplx.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

General test code for C# can be found here

```
public static void EcplxTest1()
{
    Console.WriteLine("<H1 Title=" + "\"" + "EcplxTest1"  + "\"" + ">");

    var a = ecplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = ecplx.asin(a);
    Console.WriteLine("res1 = ecplx.asin(a) {0}", res1);

    var res2 = ecplx.sin(a);
    Console.WriteLine("res2 = ecplx.sin(a) {0}", res2);

    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the DataXlCalcNet repository or in the corresponding local DataXlCalcNet folder in the file D05b_Ecplx.cs.

1.6.5.3 Examples in Python, ereal

General test code for Python can be found here

```
import math
from xlcalcnet import ereal
from decimal import Decimal
from fractions import Fraction
i = 232945639845394856394563936482734638475398457398457 3

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D05b_ECplx.py.

1.6.5.5 Notes regarding the implementation in C# and C++

The C# source code for the module `ereal` can be found here: ereal.cs.

The C# source code for the module `ecplx` can be found here: ecplx.cs.

The C++ source code supporting scalars in general which is called from `ereal.cs` and `ecplx.cs` can be found here: UseXReal.cpp.

The C++ source code which interacts directly with Boost can be found here: BoostXReal.cpp.

The C++ source code supporting Eigen which is called from `ereal.cs` and `ecplx.cs` can be found here: UseEigenXReal.cpp.

The C++ source code which interacts directly with Eigen can be found in the folder: BoostEigenMath.cpp.

1.6.6 Binary floating point, quadruple precision: `qreal` and `qcplx`

The C# modules `qreal` and `qcplx` provide support for real and complex floating point numbers in quadruple precision (see https://en.wikipedia.org/wiki/Quadruple-precision_floating-point_format). The corresponding real and complex data types, `Quadruple` and `QuadrupleC`, have been added as objects in XlCalcNet (and have therefore the overhead of objects). They are implemented in software, using the `float128` data type of Boost Multiprecision. This means that the routines in quadruple precision provided in Boost and Eigen are much slower than the corresponding routines in extended precision.

The C# modules `qreal` and `qcplx` fully support Boost.Math and Eigen.

1.6.6.1 Examples in C#, `qreal`

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some qreal functions");
    QrealTest0();
    QrealTest1();
}
```

General test code for C# can be found here

```
public static void QcplxTest0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "QcplxTest0"  + "\"" + ">");

    var a = qcplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = qcplx.abs(a);
    Console.WriteLine("res1 = qcplx.abs(a): {0}", res1);

    var res2 = qcplx.exp(a);
    Console.WriteLine("res2 = qcplx.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

General test code for C# can be found here

```
public static void QcplxTest1()
{
    Console.WriteLine("<H1 Title=" + "\"" + "QcplxTest1"  + "\"" + ">");

    var a = qcplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = qcplx.asin(a);
    Console.WriteLine("res1 = qcplx.asin(a) {0}", res1);

    var res2 = qcplx.sin(a);
    Console.WriteLine("res2 = qcplx.sin(a) {0}", res2);

    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D06a_Qreal.cs.

1.6.6.2 Examples in C#, `qcplx`

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some qreal functions");
    QrealTest0();
    QrealTest1();
}
```

General test code for C# can be found here

```
public static void QcplxTest0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "QcplxTest0"  + "\"" + ">");

    var a = qcplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = qcplx.abs(a);
    Console.WriteLine("res1 = qcplx.abs(a): {0}", res1);

    var res2 = qcplx.exp(a);
    Console.WriteLine("res2 = qcplx.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

General test code for C# can be found here

```
public static void QcplxTest1()
{
    Console.WriteLine("<H1 Title=" + "\"" + "QcplxTest1"  + "\"" + ">");

    var a = qcplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = qcplx.asin(a);
    Console.WriteLine("res1 = qcplx.asin(a) {0}", res1);

    var res2 = qcplx.sin(a);
    Console.WriteLine("res2 = qcplx.sin(a) {0}", res2);

    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D02b_Qcplx.cs.

1.6.6.3 Examples in Python, qreal

1.6.6.5 Notes regarding the implementation in C# and C++

The C# source code for the module `qreal` can be found here: qreal.cs.

The C# source code for the module `qcplx` can be found here: qcplx.cs.

The C++ source code supporting scalars in general which is called from `qreal.cs` and `qcplx.cs` can be found here: UseQReal.cpp.

The C++ source code which interacts directly with Boost can be found here: BoostQReal.cpp.

The C++ source code supporting Eigen which is called from `qreal.cs` and `qcplx.cs` can be found here: UseEigenQReal.cpp.

The C++ source code which interacts directly with Eigen can be found in the folder: BoostEigenMath.cpp.

1.6.7 Binary floating point, octuple precision: `oreal` and `ocplx`

The C# modules `oreal` and `ocplx` provide support for real and complex floating point numbers in octuple precision (see https://en.wikipedia.org/wiki/Octuple-precision_floating-point_format). The corresponding real and complex data types, `Octuple` and `OctupleC`, have been added as objects in XlCalcNet (and have therefore the overhead of objects). They are implemented in software, using the `cpp_bin_float_oct` data type of Boost Multiprecision. The routines in octuple precision provided in Boost and Eigen are typically much slower than the corresponding routines in quadruple precision.

The C# modules `oreal` and `ocplx` fully support Boost.Math and Eigen.

1.6.7.1 Examples in C#, `oreal`

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some oreal functions");
    OrealTest0();
    OrealTest1();
}
```

General test code for C# can be found here

```
public static void OcplxTest0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "OcplxTest0"  + "\"" + ">");

    var a = ocplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = ocplx.abs(a);
    Console.WriteLine("res1 = ocplx.abs(a): {0}", res1);

    var res2 = ocplx.exp(a);
    Console.WriteLine("res2 = ocplx.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

General test code for C# can be found here

```
public static void OcplxTest1()
{
    Console.WriteLine("<H1 Title=" + "\"" + "OcplxTest1"  + "\"" + ">");

    var a = ocplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = ocplx.asin(a);
    Console.WriteLine("res1 = ocplx.asin(a) {0}", res1);

    var res2 = ocplx.sin(a);
    Console.WriteLine("res2 = ocplx.sin(a) {0}", res2);

    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D07a_Oreal.cs.

1.6.7.2 Examples in C#, `ocplx`

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some oreal functions");
    OrealTest0();
    OrealTest1();
}
```

General test code for C# can be found here

```
public static void OcplxTest0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "OcplxTest0"  + "\"" + ">");

    var a = ocplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = ocplx.abs(a);
    Console.WriteLine("res1 = ocplx.abs(a): {0}", res1);

    var res2 = ocplx.exp(a);
    Console.WriteLine("res2 = ocplx.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

General test code for C# can be found here

```
public static void OcplxTest1()
{
    Console.WriteLine("<H1 Title=" + "\"" + "OcplxTest1"  + "\"" + ">");

    var a = ocplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = ocplx.asin(a);
    Console.WriteLine("res1 = ocplx.asin(a) {0}", res1);

    var res2 = ocplx.sin(a);
    Console.WriteLine("res2 = ocplx.sin(a) {0}", res2);

    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D07b_Ocplx.cs.

1.6.7.5 Notes regarding the implementation in C# and C++

The C# source code for the module `oreal` can be found here: oreal.cs.

The C# source code for the module `ocplx` can be found here: ocplx.cs.

The C++ source code supporting scalars in general which is called from `oreal.cs` and `ocplx.cs` can be found here: UseOReal.cpp.

The C++ source code which interacts directly with Boost can be found here: BoostSReal.cpp.

The C++ source code supporting Eigen which is called from `oreal.cs` and `ocplx.cs` can be found here: UseEigenSReal.cpp.

The C++ source code which interacts directly with Eigen can be found in the folder: BoostEigenMath.cpp.

1.6.8 Use of Numpy with scalar functions written in C#: `np53`, `np53c`

Some text

1.6.9 Building the underlying C#, C/C++ and Pascal libraries

On the Pascal/C/C++ side, XlCalcNet uses DAMath, Boost Math, Boost Multiprecision, Boost Odeint and Eigen to provide numerical functions in single, double, extended, quadruple and octuple precision, which are available to the user both from C# and Python.

The SourceOfBasicLibraries repository provides copies of the source code of the underlying numerical libraries, which are required to build the XlCalcNet library. These copies also include small patches, as required. They are provided to make it easier to reproduce the compilation results, as distributed as part of the XlCalcNet repository.

1.6.9.1 Installing MSYS2

Text descibing MSYS2

1.6.9.2 Eigen, (version 5.0.1)

Text descibing Eigen

1.6.9.3 Boost, (version 1.90.0)

Text descibing Boost

1.6.9.4 DAMath (version 2.27)

Text descibing DAMath

1.6.9.5 FixedPreNet (version 1.0.0)

Text descibing FixedPreNet

1.7 Mathematical functions based on XlCalcNet2 (C#, can be called from Python)

Assuming that the Python batch files have been installed as described *here*, XlCalcNet2 can be installed by double-clicking on the batch file `A13installxlcalcnet2.bat` in the `C:\Python313` folder.

1.7.1 Binary floating point, multiple precision: `mreal`, `mcplx`

The C# modules `mreal` and `mcplx` provide support for real and complex floating point numbers with an arbitrary precision significand and a fixed size exponent. The corresponding real and complex data types, `Mpfr` and `MpfrC`, have been added as objects in XlCalcNet2 (and have therefore the overhead of objects). They are implemented in software, using the `mpfr_t` data type of the MPFR library (see https://www.mpfr.org/) and the `mpc_t` data type of the MPC library (see https://www.multiprecision.org/mpc/).

The C# modules `mreal` and `mcplx` fully support Boost.Math and Eigen.

1.7.1.1 Examples in C#, `mreal`

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some mreal functions");
    MrealTest0();
    MrealTest1();
}
```

General test code for C# can be found here

```
public static void McplxTest0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "McplxTest0"  + "\"" + ">");

    var a = mcplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = mcplx.abs(a);
    Console.WriteLine("res1 = mcplx.abs(a): {0}", res1);

    var res2 = mcplx.exp(a);
    Console.WriteLine("res2 = mcplx.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

General test code for C# can be found here

```
public static void McplxTest1()
{
    Console.WriteLine("<H1 Title=" + "\"" + "McplxTest1"  + "\"" + ">");

    var a = mcplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = mcplx.asin(a);
    Console.WriteLine("res1 = mcplx.asin(a) {0}", res1);
```

(continues on next page)

(continued from previous page)

```
    var res2 = mcplx.sin(a);
    Console.WriteLine("res2 = mcplx.sin(a) {0}", res2);

    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D01a_Mreal.cs.

1.7.1.2 Examples in C#, `mcplx`

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some mreal functions");
    MrealTest0();
    MrealTest1();
}
```

General test code for C# can be found here

```
public static void McplxTest0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "McplxTest0"  + "\"" + ">");

    var a = mcplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = mcplx.abs(a);
    Console.WriteLine("res1 = mcplx.abs(a): {0}", res1);

    var res2 = mcplx.exp(a);
    Console.WriteLine("res2 = mcplx.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

General test code for C# can be found here

```
public static void McplxTest1()
{
    Console.WriteLine("<H1 Title=" + "\"" + "McplxTest1"  + "\"" + ">");

    var a = mcplx.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = mcplx.asin(a);
    Console.WriteLine("res1 = mcplx.asin(a) {0}", res1);

    var res2 = mcplx.sin(a);
    Console.WriteLine("res2 = mcplx.sin(a) {0}", res2);

    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D01b_Mcplx.cs.

1.7.1.3 Examples in Python, `mreal`

General test code for Python can be found here

```
import math
from xlcalcnet import mreal
from decimal import Decimal
from fractions import Fraction
i = 232945639845394856394563936482734638475398457398457 3

```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D02b_TestMCplx.py.

1.7.1.5 Notes regarding the implementation in C# and C++

The C# source code for the module `mreal` can be found here: mreal.cs.

The C# source code for the module `mcplx` can be found here: mcplx.cs.

The C++ source code supporting scalars in general which is called from `mreal.cs` and `mcplx.cs` can be found here: UseMpfr.cpp.

The C++ source code which interacts directly with Boost can be found here: BoostMpfr.cpp.

The C++ source code supporting Eigen which is called from `mreal.cs` and `mcplx.cs` can be found here: UseAnyEigenMat.cpp.

The C++ source code which interacts directly with Eigen can be found in the folder: BoostEigenMath.cpp.

1.7.2 Binary arbitrary precision ball: `aflint` and `aflintc`

The C# modules `aflint` and `aflintc` provide support for real and complex ball arithmetic with an arbitrary precision significand and an arbitrary size exponent. The corresponding real and complex data types, `Arb` and `ArbC`, have been added as objects in XlCalcNet2 (and have therefore the overhead of objects). They are implemented in software, using the `arb_t` and and `acb_t` data types of the FLINT library (see https://flintlib.org/).

The C# modules `mreal` and `mcplx` partially support Eigen.

Note: Exponent soft maximum and minimum

1.7.2.1 Examples in C#, `aflint`

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some aflint functions");
    AflintTest0();
    AflintTest1();
}
```

General test code for C# can be found here

```
public static void AflintcTest0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "AflintcTest0"  + "\"" + ">");

    var a = aflintc.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = aflintc.abs(a);
    Console.WriteLine("res1 = aflintc.abs(a): {0}", res1);

    var res2 = aflintc.exp(a);
    Console.WriteLine("res2 = aflintc.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

General test code for C# can be found here

```
public static void AflintcTest1()
{
    Console.WriteLine("<H1 Title=" + "\"" + "AflintcTest1"  + "\"" + ">");

    var a = aflintc.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = aflintc.asin(a);
    Console.WriteLine("res1 = aflintc.asin(a) {0}", res1);

    var res2 = aflintc.sin(a);
    Console.WriteLine("res2 = aflintc.sin(a) {0}", res2);

    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the DataXlCalcNet repository or in the corresponding local DataXlCalcNet folder in the file D02a_Aflint.cs.

1.7.2.2 Examples in C#, aflintc

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some aflint functions");
    AflintTest0();
    AflintTest1();
}
```

General test code for C# can be found here

```
public static void AflintcTest0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "AflintcTest0"  + "\"" + ">");

    var a = aflintc.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = aflintc.abs(a);
    Console.WriteLine("res1 = aflintc.abs(a): {0}", res1);

    var res2 = aflintc.exp(a);
    Console.WriteLine("res2 = aflintc.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

General test code for C# can be found here

```
public static void AflintcTest1()
{
    Console.WriteLine("<H1 Title=" + "\"" + "AflintcTest1"  + "\"" + ">");

    var a = aflintc.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = aflintc.asin(a);
    Console.WriteLine("res1 = aflintc.asin(a) {0}", res1);

    var res2 = aflintc.sin(a);
    Console.WriteLine("res2 = aflintc.sin(a) {0}", res2);

    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the DataXlCalcNet repository or in the corresponding local DataXlCalcNet folder in the file D02b_Aflintc.cs.

1.7.2.3 Examples in Python, `aflint`

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D02b_AFlintc.py.

1.7.2.5 Notes regarding the implementation in C# and C++

The C# source code for the module `aflint` can be found here: aflint.cs.

The C# source code for the module `aflintc` can be found here: aflintc.cs.

The C++ source code supporting scalars in general which is called from `aflint.cs` and `aflintc.cs` can be found here: UseArb.cpp.

The C++ source code supporting Eigen which is called from `aflint.cs` and `aflintc.cs` can be found here: UseAnyEigenMat.cpp.

The C++ source code which interacts directly with Eigen can be found in the folder: BoostEigenMath.cpp.

1.7.3 Binary floating point, single precision: `sflint` and `sflintc`

The C# modules `sflint` and `sflintc` provide a rich set of elementary and special real and complex scalar functions for the `Single` and `Single` data types, with the actual calculations done using the `Arb` and `ArbC` data types, which allows control of the absolute and relative error of the result.

1.7.3.1 Examples in C#, sflint

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some sflint functions");
    SflintTest0();
    SflintTest1();
}
```

General test code for C# can be found here

```
public static void SflintcTest0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "SflintcTest0"  + "\"" + ">");

    var a = qflintc.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = qflintc.abs(a);
    Console.WriteLine("res1 = qflintc.abs(a): {0}", res1);

    var res2 = qflintc.exp(a);
    Console.WriteLine("res2 = qflintc.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D03a_Sflint.cs.

1.7.3.2 Examples in C#, sflintc

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some sflint functions");
    SflintTest0();
    SflintTest1();
}
```

General test code for C# can be found here

```
public static void SflintcTest0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "SflintcTest0"  + "\"" + ">");

    var a = qflintc.t(3.5, 6.3);
```

(continues on next page)

(continued from previous page)

```
    Console.WriteLine("a: {0}", a);

    var res1 = qflintc.abs(a);
    Console.WriteLine("res1 = qflintc.abs(a): {0}", res1);

    var res2 = qflintc.exp(a);
    Console.WriteLine("res2 = qflintc.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D03b_Sflintc.cs.

    print('z = eflint.exp(5):', z)
    z = eflint.exp("5.5")
    print('z = eflint.exp("5.5"):', z)
    print('</H1>')
```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D05a_EFlint.py.

1.7.5.4 Examples in Python, `eflintc`

General test code for Python can be found here

```
import math
from xlcalcnet import eflint
from decimal import Decimal
from fractions import Fraction
i = 232945639845394856394563936482734638475398457398457 3
```

```
def main_tests():
    general_assignments()
    functions_with_argument_conversion()
    arithmetic_operators_with_eflint()
```

General test code can be found here

```
def general_assignments():
    print()
    print('<H1 Title="General assignments and conversions">')

    x = eflint.t(i)
    print('x = eflint.t(i):', x)

    x = eflint.t(5.7)
    print('x = eflintT(5.7):', x)

    x = eflint.t(5.7)
    print('x = eflintT(5.7):', x)
    x0 = eflint.t(232945639845394856394563936482734 6)
    print('x0 = eflintT(232945639845394856394563936482734 6', x0)
    x1 = eflint.t("232945639845394856394563936482734 6")
    print('x1 = eflint.t("232945639845394856394563936482734 6"):', x1)
    x = eflint.t("5.5")
    print('x = eflintT("5.5"):', x)

    print()
    x = eflint.t(55)
    print('x = eflint.t(5):', x)
    y = eflint.exp(x)
    print('y = eflint.exp(x):', y)

    z = eflint.exp(5.5)
    print('z = eflint.exp(5.5):', z)
    z = eflint.exp(5)
    print('z = eflint.exp(5):', z)
    z = eflint.exp("5.5")
    print('z = eflint.exp("5.5"):', z)
    print('</H1>')
```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D05b_EFlintc.py.

1.7.5.5 Notes regarding the implementation in C# and C++

The C# source code for the modules `eflint` and `eflintc` can be found here: erealcplxflint.cs.

The C++ source code which is called from `erealcplxflint.cs` can be found here: UseXReal.cpp.

1.7.6 Binary floating point, quadruple precision: `qflint` and `qflintc`

The C# modules `qflint` and `qflintc` provide a rich set of elementary and special real and complex scalar functions for the `Quadruple` and `QuadrupleC` data types, with the actual calculations done using the `Arb` and `ArbC` data types, which allows control of the absolute and relative error of the result.

1.7.6.1 Examples in C#, `qflint`

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some qflint functions");
    SflintTest0();
    SflintTest1();
}
```

General test code for C# can be found here

```
public static void QflintcTest0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "QflintcTest0"  + "\"" + ">");

    var a = qflintc.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = qflintc.abs(a);
    Console.WriteLine("res1 = qflintc.abs(a): {0}", res1);

    var res2 = qflintc.exp(a);
    Console.WriteLine("res2 = qflintc.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D06a_Qflint.cs.

1.7.6.2 Examples in C#, `qflintc`

General test code for C# can be found here

```
#region Usings
using System;
using System.Numerics;
using FixedPrecNet;
#endregion

public static void MainTests()
{
    Console.WriteLine("Demo of some qflint functions");
    SflintTest0();
    SflintTest1();
}
```

General test code for C# can be found here

```
public static void QflintcTest0()
{
    Console.WriteLine("<H1 Title=" + "\"" + "QflintcTest0"  + "\"" + ">");

    var a = qflintc.t(3.5, 6.3);
    Console.WriteLine("a: {0}", a);

    var res1 = qflintc.abs(a);
    Console.WriteLine("res1 = qflintc.abs(a): {0}", res1);

    var res2 = qflintc.exp(a);
    Console.WriteLine("res2 = qflintc.exp(a): {0}", res2);

    Console.WriteLine("</H1>");
}
```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D06b_Qflintc.cs.

1.7.6.3 Examples in Python, `qflint`

General test code for Python can be found here

```
import math
from xlcalcnet import qflint
from decimal import Decimal
from fractions import Fraction
i = 232945639845394856394563936482734638475398457398457 3984573

```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D08a_MFlint.py.

1.7.8.4 Examples in Python, `mflintc`

General test code for Python can be found here

```
import math
from xlcalcnet import mflint
from decimal import Decimal
from fractions import Fraction
i = 232945639845394856394563936482734638475398457398457 3
```

```
def main_tests():
    general_assignments()
    functions_with_argument_conversion()
    arithmetic_operators_with_mflint()
```

General test code can be found here

```
def general_assignments():
    print()
    print('<H1 Title="General assignments and conversions">')

    x = mflint.t(i)
    print('x = mflint.t(i):', x)

    x = mflint.t(5.7)
    print('x = mflintT(5.7):', x)

    x = mflint.t(5.7)
    print('x = mflintT(5.7):', x)
    x0 = mflint.t(23294563984539485639456393648273)
    print('x0 = mflintT(23294563984539485639456393648273', x0)
    x1 = mflint.t("23294563984539485639456393648273")
    print('x1 = mflint.t("23294563984539485639456393648273"):', x1)
    x = mflint.t("5.5")
    print('x = mflintT("5.5"):', x)

    print()
    x = mflint.t(55)
    print('x = mflint.t(5):', x)
    y = mflint.exp(x)
    print('y = mflint.exp(x):', y)

    z = mflint.exp(5.5)
    print('z = mflint.exp(5.5):', z)
    z = mflint.exp(5)
    print('z = mflint.exp(5):', z)
    z = mflint.exp("5.5")
    print('z = mflint.exp("5.5"):', z)
    print('</H1>')
```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder in the file D08b_MFlintc.py.

1.7.8.5 Notes regarding the implementation in C# and C++

The C# source code for the modules `mflint` and `mflintc` can be found here: mrealcplxflint.cs.

The C++ source code which is called from `mrealcplxflint.cs` can be found here: UseMpfr.cpp.

1.7.9 Building the underlying C# and C/C++ libraries

The XlCalcNet2 library, which is licensed under the LGPL-3.0 and is therefore provided in a separate repository, is based on Boost Math, Boost Multiprecision, Boost Odeint, Eigen, GMP, MPFR, MPC and FLINT and provides functions for the same data types as XlCalcNet and also in arbitrary precision, which are available to the user both from C# and Python.

The SourceOfBasicLibraries2 repository provides copies of the source code of the underlying numerical libraries, which are required (in addition to Eigen and Boost, see SourceOfBasicLibraries) to build the XlCalcNet2 library.. These copies also include small patches and .sh files, as required. They are provided to make it easier to reproduce the compilation results, as distributed as part of the XlCalcNet2 repository.

1.7.9.1 GMP (version 6.3.0)

Text descibing GMP, including config files

1.7.9.2 MPFR (version 4.2.2)

Text descibing MPFR, including config files

1.7.9.3 MPC (version 1.3.1)

Text descibing MPC, including config files

1.7.9.4 FLINT (version 3.4.0)

Text descibing FLINT, including config files

1.7.9.5 ArbPreNet (version 1.0.0)

Text descibing ArbPreNet

1.8 Building user libraries and documenting them

XlCalcNet allows the user to build libraries of user defined functions in Python and C#, which can be used from spreadsheet formulas in Microsoft Excel and LibreOffice Calc, as well as from Python scripts and C# programs. The user libraries can be documented using Sphinx, which allows to build documentation in html and pdf format.

Basic examples of building a user library are provided for Python in the subfolders of the `A03_UserlibPython` folder, and for C# in the subfolders of the `A04_UserlibCSharp` folder, which can be used as templates for building more complex user libraries.

The user library can be documented using Sphinx, which allows to build documentation in html and pdf format. The documentation can be built starting with examples in the `A05_UserlibDocs` folder, which can be used as a template for documenting more complex user libraries. The documentation for the already included starting user libraray is part of this manual. It is written in the same style as this manual and comprises two parts: User library: numerical; and User library: graphics.

Examples of using the user libraries are provided in the subfolders of the `A06_UserlibExamplesPython` folder for Python and in the `A07_UserlibExamplesCSharp` folder for C#.

1.8.1 Building a library of user defined Python functions

In Python, the user library is built in the subfolders of the `A03_UserlibPython` folder, which contains Python modules with the user defined functions. The modules can be imported in Python scripts and used from spreadsheet formulas in Microsoft Excel and LibreOffice Calc. The functions are decribed here.

These functions can be tested in the subfolders of the `A06_UserlibExamplesPython` folder.

1.8.2 Building a library of user defined functions in C#

The library of user defined functions in C# is built in form of 2 dynamic link libraries (DLLs), which are called `UserFixedPrecNet.dll` and `UserArbPrecNet.dll` and which are written into the Binary Output Folder. These functions are described here.

There is also a third DLL called `UserMpPrecNet.dll`, which is used by the Python user library. This DLL is also written into the Binary Output Folder.

1.8.3 Sphinx: building documentation for software with Python (html and pdf)

This manual is written in reStructuredText (reST) format, which is a lightweight markup language. The manual is built using Sphinx, which is a tool that makes it easy to create intelligent and beautiful documentation for Python projects (or other software projects). Sphinx uses reStructuredText as its markup language and can generate output in various formats, including HTML and PDF.

To build the documentation, you need to have Sphinx installed.

See also: https://www.sphinx-doc.org/en/master/

You also need to install 3 additional Sphinx extensions that are used in this manual: the Sphinx Book Theme, the Sphinx Copybutton extension, and the Sphinx Contrib Bibtex extension

Assuming that the Python batch files have been installed as described *here*, these four packages can be installed by double-clicking on the batch files `A14installSphinx.bat`, `A15install_sphinx_book_theme.bat`, `A16install_sphinx_copybutton.bat`, `A17install_sphinxcontribute_bibtex.bat`, in the `C:\Python313` folder.

With these packages installed, you can build the documentation of the user library by opening in the Tiny IDE the file `A05_UserlibDocs\B01_Lib01\_static\builddoc.py`. In the Tiny IDE main menu, click on `Run`. The HTML documentation will then be built in the subfolder `html` in the `XlCalcNetIDE` folder in the AppDataLocal folder. If built has succeded, the documentation will be opened automatically. The html documentation can be viewed by opening the file `index.html` in a web browser.

CHAPTER

TWO

BASIC FLOATING POINT FUNCTIONS

The source code for the C# tests in Visual Studio can be found online in the `XlCalcNet` repository or in the corresponding local `XlCalcNet` folder in the file B02_BasicFloatingPoint.cs.

2.1 Operator overloading, general real functions

2.1.1 Operator overloading: scope and restrictions

Compatible operators

2.1.2 The cost of creating and destroying objects

Some text

2.1.3 Raw addition of two floating point numbers

`ctx.`**`rawadd`**(*res*, *x*, *y*)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Sets `res` to the sum of the floating point number `x` and `y`.

An example in Python

```
>>> from xlcalcnet import ecplx
>>> ecplx.Abs(0.5)
ecplx('5.235987755982988730 7E-1')
>>> ecplx.Abs('0.1')
ecplx('5.351847902755998475 4E-1')
```

2.1.4 Raw subtraction of two floating point numbers

`ctx.`**`rawsub`**(*res*, *x*, *y*)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Sets `res` to the difference of the floating point numbers `x` and `y`.

An example in Python

```
>>> from xlcalcnet import ecplx
>>> ecplx.Abs(0.5)
ecplx('5.235987755982988730 7E-1')
>>> ecplx.Abs('0.1')
ecplx('5.351847902755998475 4E-1')
```

2.1.5 Raw multiplication of two floating point numbers

`ctx.rawmul(res, x, y)`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Sets `res` to the product of the floating point numbers `x` and `y`.

An example in Python

```
>>> from xlcalcnet import ecplx
>>> ecplx.Abs(0.5)
ecplx('5.235987755982988730 7E-1')
>>> ecplx.Abs('0.1')
ecplx('5.351847902755998475 4E-1')
```

2.1.6 Raw division of two floating point numbers

`ctx.rawdiv(res, x, y)`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Sets `res` to the quotient of the floating point numbers `x` and `y`.

An example in Python

```
>>> from xlcalcnet import ecplx
>>> ecplx.Abs(0.5)
ecplx('5.235987755982988730 7E-1')
>>> ecplx.Abs('0.1')
ecplx('5.351847902755998475 4E-1')
```

2.1.7 Raw addition of a floating point number and a signed 32 bit integer

`ctx.rawaddint32(res, x, i)`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Sets `res` to the sum of the floating point number `x` and the signed 32 bit integer `i`.

An example in Python

```
>>> from xlcalcnet import ecplx
>>> ecplx.Abs(0.5)
ecplx('5.235987755982988730 7E-1')
>>> ecplx.Abs('0.1')
ecplx('5.351847902755998475 4E-1')
```

2.1.8 Raw subtraction of a floating point number and a signed 32 bit integer

`ctx.rawsubint32(res, x, i)`

`ctx.rawint32sub(res, x, i)`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Sets `res` to the difference of the floating point number `x` and the signed 32 bit integer `i` (`SubInt`) or to the difference of the signed 32 bit integer `i` the floating point number `x` (`IntSub`).

An example in Python

```
>>> from xlcalcnet import ecplx
>>> ecplx.Abs(0.5)
ecplx('5.235987755982988730 7E-1')
>>> ecplx.Abs('0.1')
ecplx('5.351847902755998475 4E-1')
```

2.1.9 Raw multiplication of a floating point number and a signed 32 bit integer

`ctx.`**`rawmulint32`**(*res*, *x*, *i*)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Sets `res` to the product of the floating point number `x` and the signed 32 bit integer `i`.

An example in Python

```
>>> from xlcalcnet import ecplx
>>> ecplx.Abs(0.5)
ecplx('5.235987755982988730 7E-1')
>>> ecplx.Abs('0.1')
ecplx('5.351847902755998475 4E-1')
```

2.1.10 Raw division of a floating point number and a signed 32 bit integer

`ctx.`**`rawdivint32`**(*res*, *x*, *i*)

`ctx.`**`rawint32div`**(*res*, *i*, *x*)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Sets `res` to the quotient of the floating point number `x` and the signed 32 bit integer `i` (`DivInt`) or to the quotient of the signed 32 bit integer `i` the floating point number `x` (`IntDiv`).

An example in Python

```
>>> from xlcalcnet import ecplx
>>> ecplx.Abs(0.5)
ecplx('5.235987755982988730 7E-1')
>>> ecplx.Abs('0.1')
ecplx('5.351847902755998475 4E-1')
```

2.1.11 Fused multiplication and addition: $\mathrm{fma}(x, y, z)$

`ctx.`**`fma`**(*x*, *y*, *z*)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

If successful, returns the value of x * y + z as if calculated to infinite precision and rounded once to fit the result type (or, alternatively, calculated as a single ternary floating-point operation).

See also: https://en.cppreference.com/w/cpp/numeric/math/fma

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Copysign(0.5, 2)
ereal('5.235987755982988730 7E-1')
>>> ereal.Copysign('0.51', 2)
ereal('5.351847902755998475 4E-1')
```

2.1.12 Maximum of two floating point numbers: $\mathrm{fmax}(x, y)$

`ctx.`**`fmax`**(x, e)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the maximum of two floating point numbers; $x, y \neq$ NAN.

Returns the larger of two floating point arguments, treating NaNs as missing data (between a NaN and a numeric value, the numeric value is chosen). Only if both arguments are NaN, NaN is returned.

This function is not required to be sensitive to the sign of zero, although some implementations additionally enforce that if one argument is +0 and the other is -0, then +0 is returned.

See also: https://en.cppreference.com/w/cpp/numeric/math/fmax

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Max(0.5, 2)
ereal('5.2359877559829887307E-1')
>>> ereal.Max('0.51', 2)
ereal('5.351847902755998475 4E-1')
```

2.1.13 Minimum of two floating point numbers: $\mathrm{fmin}(x, y)$

`ctx.`**`fmin`**(x, y)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the minimum of two floating point numbers; $x, y \neq$ NAN.

Returns the smaller of two floating point arguments, treating NaNs as missing data (between a NaN and a numeric value, the numeric value is chosen). Only if both arguments are NaN, NaN is returned.

This function is not required to be sensitive to the sign of zero, although some implementations additionally enforce that if one argument is +0 and the other is -0, then -0 is returned.

See also: https://en.cppreference.com/w/cpp/numeric/math/fmin

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Min(0.5, 2)
ereal('5.2359877559829887307E-1')
>>> ereal.Min('0.51', 2)
ereal('5.351847902755998475 4E-1')
```

2.2 Machine constants, general

2.2.1 Zero, positive zero

property `ctx.zero`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns $+0$.

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.Zero()
ereal('0.000000000000000000000')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.Zero()
0.0
```

2.2.2 Negative zero

property `ctx.negzero`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns -0.

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.Zero()
ereal('0.000000000000000000000')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.Zero()
0.0
```

2.2.3 One

property `Cxt.one`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns 1

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.One()
ereal('1.000000000000000000000')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.One()
1.0
```

2.2.4 Positive infinity

`ctx.inf()`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns $+\infty$

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.PositiveInfinity()
ereal('+Inf')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.PositiveInfinity()
+Inf
```

2.2.5 Negative infinity

`ctx.neginf()`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the representation of $-\infty$

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.NegativeInfinity()
ereal('-Inf')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.NegativeInfinity()
-Inf
```

2.2.6 NaN (Not a Number)

`ctx.nan()`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns `NaN` (Not a Number).

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.Nan()
ereal('Nan')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.Nan()
Nan
```

2.3 Properties of numbers

2.3.1 Test for signbit

`ctx.`**`signbit`**`(`x`)`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns `True` if the sign bit of x is set.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.IsInfinity(0.5)
False
>>> ereal.IsInfinity('inf')
True
```

2.3.2 Test for a finite number

`ctx.`**`isfinite`**`(`x`)`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns `True` if x is neither $+\infty$ nor $-\infty$ nor `NaN`.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.IsFinite(0.5)
False
>>> ereal.IsFinite('inf')
True
```

2.3.3 Test for infinity

`ctx.`**`isinf`**`(`x`)`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns `True` if x is either $+\infty$ or $-\infty$.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.IsInfinity(0.5)
False
>>> ereal.IsInfinity('inf')
True
```

2.3.4 Test for positive infinity

`ctx.`**`isposinf`**`(`x`)`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns `True` if x is $+\infty$.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.IsPositiveInfinity(0.5)
False
```

(continues on next page)

(continued from previous page)

```
>>> ereal.IsPositiveInfinity('inf')
True
```

2.3.5 Test for negative infinity

`ctx.`**`isneginf`**(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns `True` if x is $-\infty$.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.IsNegativeInfinity(0.5)
False
>>> ereal.IsNegativeInfinity('inf')
True
```

2.3.6 Test for NaN

`ctx.`**`isnan`**(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns `True` if x is Nan (Not a number).

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.IsNan(0.5)
False
>>> ereal.IsNan('inf')
True
```

2.3.7 Test for zero

`ctx.`**`iszero`**(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns `True` if x is 0 (+0 or -0).

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.IsNan(0.5)
False
>>> ereal.IsNan('inf')
True
```

2.3.8 Test for one

`ctx.`**`isone`**(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns `True` if x is 1.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.IsNan(0.5)
False
>>> ereal.IsNan('inf')
True
```

2.3.9 Test if a number is an integer

`ctx.isinteger`(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns `True` if x is an integer.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.IsNan(0.5)
False
>>> ereal.IsNan('inf')
True
```

2.3.10 Test if a number is a simple number (not an infinity or NaN)

`ctx.isnumber`(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns `True` if x is an integer.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.IsNan(0.5)
False
>>> ereal.IsNan('inf')
True
```

2.3.11 Test if a number is a regular number (not zero, an infinity or NaN)

`ctx.isregular`(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns `True` if x is a regular number (not zero, an infinity or NaN).

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.IsNan(0.5)
False
>>> ereal.IsNan('inf')
True
```

2.3.12 Test if a number is a normal number (not subnormal, zero, an infinity or NaN)

`ctx.isnormal`(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns `True` if x is a normal number (not subnormal, zero, an infinity or NaN)

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.IsNan(0.5)
False
>>> ereal.IsNan('inf')
True
```

2.3.13 Test if 2 numbers are unordered

`ctx.`**`isunordered`**(x, y)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns `True` if x and y are unordered.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.IsNan(0.5)
False
>>> ereal.IsNan('inf')
True
```

2.3.14 Test if a number fits in a signed 32 bit integer

`ctx.`**`fitsint32`**(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Test if a number fits in a signed 32 bit integer

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.IsNan(0.5)
False
>>> ereal.IsNan('inf')
True
```

2.3.15 Test if a number fits in a signed 64 bit integer

`ctx.`**`fitsint64`**(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Test if a number fits in a signed 64 bit integer

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.IsNan(0.5)
False
>>> ereal.IsNan('inf')
True
```

2.4 Integer related functions

2.4.1 Integral value nearest x (rounding to nearest): $\mathrm{nearbyint}(x), \mathrm{rint}(x)$

`ctx.rint`(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the integral value (in floating-point format) nearest x, using the `rounding-to-nearest` rounding mode.

For the std::rint function:

- If num is $\pm\infty$, it is returned, unmodified.
- If num is ± 0, it is returned, unmodified.
- If num is NaN, NaN is returned.

See also: https://en.cppreference.com/w/cpp/numeric/math/nearbyint

See also: https://en.cppreference.com/w/cpp/numeric/math/rint

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Rint(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Rint('0.51')
ereal('5.351847902755998475 4E-1')
```

`ctx.nearbyint`(x)

Is an alias for `ctx.rint(x)` in this implementation. The only difference between `std::rint` and `std::nearbyint` is that `std::nearbyint` never raises `FE_INEXACT`.

2.4.2 32 bit integer nearest x (rounding to nearest): $\mathrm{lrint}(x)$

`ctx.lrint`(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns an 32 bit signed integer nearest x, using the `rounding-to-nearest` rounding mode.

If the result is outside the range representable by an 32 bit signed integer, a domain error or a range error may occur.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Rint(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Rint('0.51')
ereal('5.351847902755998475 4E-1')
```

2.4.3 64 bit integer nearest x (rounding to nearest): $\mathrm{llrint}(x)$

`ctx.llrint`(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns an 64 bit signed integer nearest x, using the `rounding-to-nearest` rounding mode.

If the result is outside the range representable by an 64 bit signed integer, a domain error or a range error may occur.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Rint(0.5)
ereal('5.23598775598298873077E-1')
>>> ereal.Rint('0.51')
ereal('5.35184790275599847540E-1')
```

2.4.4 Smallest integral value not less than x : ceil(x)

`ctx.ceil`(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the smallest integer $> x$; $|x| \leq$ MaxLongint.

See also: https://en.cppreference.com/w/cpp/numeric/math/ceil

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Ceil(0.5)
ereal('5.23598775598298873077E-1')
>>> ereal.Ceil('0.51')
ereal('5.35184790275599847540E-1')
```

2.4.5 Largest integral value not greater than x : floor(x)

`ctx.floor`(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the largest integer $< x$; $|x| \leq$ MaxLongint.

See also: https://en.cppreference.com/w/cpp/numeric/math/floor

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Floor(0.5)
ereal('5.23598775598298873077E-1')
>>> ereal.Floor('0.51')
ereal('5.35184790275599847540E-1')
```

2.4.6 Nearest integral value not greater in magnitude than x : trunc(x)

`ctx.trunc`(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the truncated value of x.

See also: https://en.cppreference.com/w/cpp/numeric/math/trunc

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Truncate(0.5)
ereal('5.23598775598298873077E-1')
>>> ereal.Truncate('0.51')
ereal('5.35184790275599847540E-1')
```

2.4.7 Nearest integral value, rounding halfway cases away from zero: $\mathrm{round}(x)$

`ctx.round`(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Computes the nearest integer (in floating-point format), rounding halfway cases away from zero, regardless of the current rounding mode.

See also: https://en.cppreference.com/w/cpp/numeric/math/round

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Round(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Round('0.51')
ereal('5.351847902755998475 4E-1')
```

2.4.8 Nearest 32 bit integer, rounding halfway cases away from zero: $\mathrm{lround}(x)$

`ctx.lround`(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the nearest 32 bit signed integer, rounding halfway cases away from zero.

See also: https://en.cppreference.com/w/cpp/numeric/math/round

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Round(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Round('0.51')
ereal('5.351847902755998475 4E-1')
```

2.4.9 Nearest 64 bit integer, rounding halfway cases away from zero: $\mathrm{llround}(x)$

`ctx.llround`(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the nearest 64 bit signed integer, rounding halfway cases away from zero.

See also: https://en.cppreference.com/w/cpp/numeric/math/round

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Round(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Round('0.51')
ereal('5.351847902755998475 4E-1')
```

2.5 Floating point functions for real numbers

2.5.1 Efficient computation of $|x| \cdot \text{sign}(y) : \text{copysign}(x, y)$

`ctx.copysign`(*mag*, *sgn*)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns $|x| \cdot \text{sign}(y)$.

See also: https://en.cppreference.com/w/cpp/numeric/math/copysign

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Copysign(0.5, 2)
ereal('5.2359877559829887307E-1')
>>> ereal.Copysign('0.51', 2)
ereal('5.3518479027559984754E-1')
```

2.5.2 Decomposition of x as $x = m \cdot 2^e; 0.5 < m < 1 : \text{frexp}(x)$

`ctx.frexp`(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`. See also Mpmath [686].

Returns (as a tuple) the mantissa m and exponent e of x with $x = m \cdot 2^e, 0.5 < m < 1$.

If x is 0, $\pm\infty$ or NaN, returns $m = x, e = 0$.

See also: https://en.cppreference.com/w/cpp/numeric/math/frexp

See also: https://en.cppreference.com/w/cpp/numeric/math/ilogb

See also: https://en.cppreference.com/w/cpp/numeric/math/logb

Ilogb: Returns base 2 exponent of x. For finite x ilogb = floor(log2($|x|$)), otherwise -MaxLongint for x = 0 or MaxLongint if x = +-INF or Nan.

Extracts the value of the unbiased exponent from the floating-point argument num, and returns it as a signed integer value. The value of the exponent returned by `std::ilogb` is always 1 less than the exponent returned by `std::frexp` because of the different normalization requirements: for the exponent e returned by `std::ilogb`, $|num * 2^{-e}|$ is between 1 and 2, but for the exponent e returned by std::frexp, $|num * 2^{-e}|$ is between 0.5 and 1.

If the implementation supports IEEE floating-point arithmetic (IEC 60559),

- If num is ± 0, $-\inf$ is returned and FE_DIVBYZERO is raised.
- If num is $\pm\inf$, $+\inf$ is returned.
- If num is NaN, NaN is returned.

In all other cases, the result is exact (FE_INEXACT is never raised) and the current rounding mode is ignored.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Frexp(0.5)
ereal('5.2359877559829887307E-1')
>>> ereal.Frexp('0.51')
ereal('5.3518479027559984754E-1')
```

2.5.3 Integral value e, from the decomposition of x as $x = m \cdot 2^e; 1 < m < 2 : \log b(x)$

`ctx.logb`(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns (as a tuple) the mantissa m and exponent e of x with $x = m \cdot 2^e, 0.5 < m < 1$.

If x is 0, $\pm\infty$ or NaN, returns $m = x, e = 0$.

See also: https://en.cppreference.com/w/cpp/numeric/math/frexp

See also: https://en.cppreference.com/w/cpp/numeric/math/ilogb

See also: https://en.cppreference.com/w/cpp/numeric/math/logb

Logb: Returns base 2 exponent of x. For finite x logb = floor(log2(|x|)), otherwise -MaxLongint for x = 0 or MaxLongint if x = +-INF or Nan.

Extracts the value of the unbiased exponent from the floating-point argument num, and returns it as a signed integer value. The value of the exponent returned by `std::ilogb` is always 1 less than the exponent returned by `std::frexp` because of the different normalization requirements: for the exponent e returned by `std::ilogb`, $|num * 2^{-e}|$ is between 1 and 2, but for the exponent e returned by std::frexp, $|num * 2^{-e}|$ is between 0.5 and 1.

If the implementation supports IEEE floating-point arithmetic (IEC 60559),

- If num is ± 0, $-\inf$ is returned and FE_DIVBYZERO is raised.
- If num is $\pm\inf$, $+\inf$ is returned.
- If num is NaN, NaN is returned.

In all other cases, the result is exact (FE_INEXACT is never raised) and the current rounding mode is ignored.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Frexp(0.5)
ereal('5.2359877559829887307E-1')
>>> ereal.Frexp('0.51')
ereal('5.3518479027559984754E-1')
```

2.5.4 32 bit integer e, from the decomposition of x as $x = m \cdot 2^e; 1 < m < 2 : \text{ilogb}(x)$

`ctx.ilogb`(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns (as a tuple) the mantissa m and exponent e of x with $x = m \cdot 2^e, 0.5 < m < 1$.

If x is 0, $\pm\infty$ or NaN, returns $m = x, e = 0$.

See also: https://en.cppreference.com/w/cpp/numeric/math/frexp

See also: https://en.cppreference.com/w/cpp/numeric/math/ilogb

See also: https://en.cppreference.com/w/cpp/numeric/math/logb

Ilogb: Returns base 2 exponent of x. For finite x ilogb = floor(log2(|x|)), otherwise -MaxLongint for x = 0 or MaxLongint if x = +-INF or Nan.

Extracts the value of the unbiased exponent from the floating-point argument num, and returns it as a signed integer value. The value of the exponent returned by `std::ilogb` is always 1 less than the exponent returned by `std::frexp` because of the different normalization requirements: for the exponent e returned by `std::ilogb`, $|num * 2^{-e}|$ is between 1 and 2, but for the exponent e returned by std::frexp, $|num * 2^{-e}|$ is between 0.5 and 1.

If the implementation supports IEEE floating-point arithmetic (IEC 60559),

- If num is ± 0, $-\inf$ is returned and FE_DIVBYZERO is raised.
- If num is $\pm\inf$, $+\inf$ is returned.
- If num is NaN, NaN is returned.

In all other cases, the result is exact (FE_INEXACT is never raised) and the current rounding mode is ignored.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Frexp(0.5)
ereal('5.2359877559829887307E-1')
>>> ereal.Frexp('0.51')
ereal('5.351847902755998475 4E-1')
```

2.5.5 Efficient computation of $x \cdot 2^e$: $\mathrm{ldexp}(x, e), \mathrm{scalbn}(x, e), \mathrm{scalbln}(x, e)$

`ctx.ldexp`(x, e)

where `ctx` is `math53`, `ctxboost` or `ctxflint`. See also Mpmath [690].

Returns $x \cdot 2^e$

On binary systems (where `FLT_RADIX` is 2), `std::scalbn` is equivalent to std::ldexp.

Although `std::scalbn` and `std::scalbln` are specified to perform the operation efficiently, on many implementations they are less efficient than multiplication or division by a power of two using arithmetic operators.

The function name stands for "new scalb", where scalb was an older non-standard function whose second argument had floating-point type.

The `std::scalbln` function is provided because the factor required to scale from the smallest positive floating-point value to the largest finite one may be greater than 32767, the standard-guaranteed INT_MAX. In particular, for the 80-bit long double, the factor is 32828.

See also: https://en.cppreference.com/w/cpp/numeric/math/ldexp

See also: https://en.cppreference.com/w/cpp/numeric/math/scalbn

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Ldexp(0.5, 2)
ereal('5.2359877559829887307E-1')
>>> ereal.Ldexp('0.51', 2)
ereal('5.351847902755998475 4E-1')
```

`ctx.scalbn`(x, e)

where `ctx` is `math53`, `ctxboost` or `ctxflint`. This is an alias of `ctx.ldexp`.

`ctx.scalbln`(x, e)

where `ctx` is `math53`, `ctxboost` or `ctxflint`. This is an alias of `ctx.ldexp`.

2.5.6 Positive difference between x and y: $\mathrm{fdim}(x, y)$

`ctx.fdim`(x, y)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the positive difference between x and y, that is, if $x > y$, returns $x - y$, otherwise (i.e. if $x \leq y$) returns +0.

See also: https://en.cppreference.com/w/cpp/numeric/math/fdim

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Copysign(0.5, 2)
ereal('5.2359877559829887307E-1')
>>> ereal.Copysign('0.51', 2)
ereal('5.351847902755998475 4E-1')
```

2.6 Fraction and remainder related functions

2.6.1 Integral and fractional part of a floating point number: $\mathrm{modf}(x)$

`ctx.`**`modf`**(x)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns (as a tuple) frac(x) and trunc(x) in ip, $|x| <$ MaxLongint

Decomposes given floating point value num into integral and fractional parts, each having the same type and sign as num. The integral part (in floating-point format) is stored in the object pointed to by iptr.

If the implementation supports IEEE floating-point arithmetic (IEC 60559),

- If num is ± 0, ± 0 is returned, and ± 0 is stored in `*iptr`.
- If num is $\pm \inf$, ± 0 is returned, and $\pm \inf$ is stored in `*iptr`.
- If num is NaN, NaN is returned, and NaN is stored in `*iptr`.

The returned value is exact, the current rounding mode is ignored.

See also: https://en.cppreference.com/w/cpp/numeric/math/modf

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Modf(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Modf('0.51')
ereal('5.351847902755998475 4E-1')
```

2.6.2 Floating point remainder: $\mathrm{fmod}(x, y)$

`ctx.`**`fmod`**(x, y)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`. See also Mpmath [676].

!!! TypeError: unsupported operand type(s) for %: 'ivmpf' and 'ivmpf' !!!

!!! TypeError: unsupported operand type(s) for %: 'arb3_t' and 'arb3_t' !!!

Converts x and y to mpmath numbers and returns $x \mod y$. For mpmath numbers, this is equivalent to `x % y`.

```
>>> from xlcalcnet import fp, mp, iv, dp, gp, ap
>>> for ctx in [fp, mp, dp, gp]: ctx.dps = 15;  print(repr(ctx.fmod(100, +ctx.pi)))
2.6106277387164134
mpf('2.6106277387164134')
Decimal('2.61062773871651')
mpfr('2.6106277387164134')
```

You can use *`fmod()`* to compute fractional parts of numbers:

```
>>> for ctx in [fp, mp, dp, gp]: ctx.dps = 15;  print(repr(ctx.fmod(10.25, 1)), end=', ')
0.25, mpf('0.25'), Decimal('0.25'), mpfr('0.25'),
```

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns $x \bmod y$, $y \neq 0$, sign(result) = sign(x).

The floating-point remainder of the division operation `x / y` calculated by this function is exactly the value `x - rem * y`, where `rem` is `x / y` with its fractional part truncated.

The returned value has the same sign as x and is less than y in magnitude.

If the implementation supports IEEE floating-point arithmetic (IEC 60559),

- If x is ± 0 and y is not zero, ± 0 is returned.
- If x is $\pm \inf$ and y is not NaN, NaN is returned and FE_INVALID is raised.
- If y is ± 0 and x is not NaN, NaN is returned and FE_INVALID is raised.
- If y is $\pm \inf$ and x is finite, x is returned.
- If either argument is NaN, NaN is returned.

See also: https://en.cppreference.com/w/cpp/numeric/math/fmod

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Fmod(0.5, 2)
ereal('5.235987755982988730 7E-1')
>>> ereal.Fmod('0.51', 2)
ereal('5.351847902755998475 4E-1')
```

2.6.3 IEEE floating point remainder: $\mathrm{remainder}(x, y)$

`ctx.`**`remainder`**(x, y)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the IEEE754 remainder x REM y = x - rmNearest(x/y)*y.

The IEEE floating-point remainder of the division operation `x / y` calculated by this function is exactly the value `x - quo * y`, where the value `quo` is the integral value nearest the exact value `x / y`. When `|quo - x / y| = 0.5`, the value `quo` is chosen to be even.

In contrast to std::fmod, the returned value is not guaranteed to have the same sign as x.

If the returned value is zero, it will have the same sign as x.

If the implementation supports IEEE floating-point arithmetic (IEC 60559),

- The current rounding mode has no effect.
- FE_INEXACT is never raised, the result is always exact.
- If x is $\pm \inf$ and y is not NaN, NaN is returned and FE_INVALID is raised.
- If y is ± 0 and x is not NaN, NaN is returned and FE_INVALID is raised.
- If either argument is NaN, NaN is returned.

See also: https://en.cppreference.com/w/cpp/numeric/math/remainder

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Remainder(0.5, 2)
ereal('5.235987755982988730 7E-1')
>>> ereal.Remainder('0.51', 2)
ereal('5.351847902755998475 4E-1')
```

2.6.4 IEEE floating point remainder and part of quotient: $\mathrm{remquo}(x, y)$

`ctx.remquo`(x, y)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the IEEE754 remainder x REM y = x - rmNearest(x/y)*y.

Computes the floating-point remainder of the division operation x/y as the `std::remainder` function does. Additionally, the sign and at least three of the last bits of x/y will be stored in quo, sufficient to determine the octant of the result within a period.(formally, stores a value whose sign is the sign of x/y and whose magnitude is congruent modulo 2^n to the magnitude of the integral quotient of x/y, where n is an implementation-defined integer greater than or equal to 3).

If the implementation supports IEEE floating-point arithmetic (IEC 60559),

The current rounding mode has no effect.

FE_INEXACT is never raised.

If x is $\pm\inf$ and y is not NaN, NaN is returned and FE_INVALID is raised.

If y is ± 0 and x is not NaN, NaN is returned and FE_INVALID is raised.

If either x or y is NaN, NaN is returned.

See also: https://en.cppreference.com/w/cpp/numeric/math/remquo

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Remainder(0.5, 2)
ereal('5.235987755982988730 7E-1')
>>> ereal.Remainder('0.51', 2)
ereal('5.351847902755998475 4E-1')
```

2.7 Functions related to mantissa width and exponent range

2.7.1 Machine Epsilon

`ctx.epsilon()`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the machine epsilon for the given data type. See also Wikipedia [1265].

See also: https://docs.python.org/3/library/sys.html#sys.float_info

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.MachineEps()
ereal('1.0842021724855044340E-19')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.MachineEps()
2.22044604925031e-16
```

2.7.2 Unit in the last place

`ctx.ulp(`x`)`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the "unit in the last place" for a specified floating-point value x, i.e.the smallest representable positive number u with $x + u > x$.

See also: https://docs.python.org/3/library/math.html#math.ulp

See also: https://en.wikipedia.org/wiki/Unit_in_the_last_place

See also: https://www.boost.org/doc/libs/1_85_0/libs/math/doc/html/math_toolkit/next_float/ulp.html

```
>>> from xlcalcnet import ereal
>>> ereal.MachineEps()
ereal('1.0842021724855044340E-19')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.MachineEps()
2.22044604925031e-16
```

2.7.3 Largest representable number

`ctx.maxvalue()`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the largest representable number for the given data type.

See also: https://docs.python.org/3/library/sys.html#sys.float_info

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.MaxValue()
ereal('1.1897314953572317650E+4932')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.MaxValue()
1.79769313486232E+308
```

2.7.4 Lowest representable number

`ctx.lowestvalue()`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the lowest representable number for the given data type.

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.MaxValue()
ereal('-1.1897314953572317650E+4932')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.MaxValue()
-1.79769313486232E+308
```

2.7.5 Smallest representable positive number

`ctx.minposvalue()`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

See also: https://docs.python.org/3/library/sys.html#sys.float_info

Returns the smallest representable positive number for the given data type.

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.MinValue()
ereal('3.3621031431120935063E-4932')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.MinValue()
2.22507385850720e-308
```

2.7.6 Next representable floating point number: $\mathrm{nexttowards}(x, y)$

`ctx.nexttowards(`x, y`)`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

See also: https://docs.python.org/3/library/math.html#math.nextafter

Returns the next representable floating point number before x in the direction of y.

See also: https://en.cppreference.com/w/cpp/numeric/math/nextafter

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Succ(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Succ('0.51')
ereal('5.351847902755998475 4E-1')
```

2.7.7 Next representable floating point number: nextabove(x)

`ctx.`**`nextabove`**`(`x`)`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Note: ctx.pred(x), ctx.succ(x).

Nextabove: Returns the next representable floating point number before x in the direction of `+Inf`.

See also: https://en.cppreference.com/w/cpp/numeric/math/nextafter

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Succ(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Succ('0.51')
ereal('5.351847902755998475 4E-1')
```

2.7.8 Next representable floating point number: nextbelow(x)

`ctx.`**`nextbelow`**`(`x`)`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Note: ctx.pred(x), ctx.succ(x).

Nextbelow: Returns the next representable floating point number before x in the direction of `-Inf`.

See also: https://en.cppreference.com/w/cpp/numeric/math/nextafter

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Succ(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Succ('0.51')
ereal('5.351847902755998475 4E-1')
```

2.8 Mathematical Constants

2.8.1 Degree

property ctx.**degree**

where ctx is math53, ctxboost or ctxflint.

Returns one degree of angle, $1^\circ = \pi/180$. See also Wikipedia [1276], MathWorld [904], Mpmath [607], Mpmath [713], Mpmath [706].

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstDegree()
ereal('1.7453292519943295769E-2')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstDegree()
0.0174532925199433
```

2.8.2 Golden ratio phi

property ctx.**phi**

where ctx is math53, ctxboost or ctxflint.

Returns the golden ratio $\phi = (1 + \sqrt{5})/2$. See also Wikipedia [1283], MathWorld [907], Mpmath [614].

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstPhi()
ereal('1.6180339887498948482')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstPhi()
1.61803398874989
```

2.8.3 Natural logarithm of 2

property ctx.**ln2**

where ctx is math53, ctxboost or ctxflint.

Returns the logarithm of 2. See also Wikipedia [1267], MathWorld [912].

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstLog2()
ereal('6.9314718055994530943E-1')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstLog2()
0.693147180559945
```

2.8.4 Natural logarithm of 10

property `ctx.ln10`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the logarithm of 10. See also MathWorld [911].

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstLog10()
ereal('2.3025850929940456840')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstLog10()
2.30258509299405
```

2.8.5 Pi (π)

property `ctx.pi`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the constant pi. See also Wikipedia [1268], MathWorld [913], Mpmath [619].

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.Pi()
ereal('3.1415926535897932385')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.Pi()
3.14159265358979
```

2.8.6 Euler e

property `ctx.e`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the constant const_e. See also Wikipedia [1272], MathWorld [914], Mpmath [604].

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstE()
ereal('3.1415926535897932385')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstE()
2.71828182845905
```

2.8.7 Euler-Mascheroni constant γ

property `ctx.egamma`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the Euler gamma constant. See also Wikipedia [1281], MathWorld [905], Mpmath [612].

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstEulerGamma()
ereal('5.7721566490153286062E-1')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstEulerGamma()
0.577215664901533
```

2.8.8 Apéry's constant

property `ctx.apery`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Represents Apery's constant. See also Wikipedia [1273], MathWorld [899], Mpmath [602].

It is an irrational number approximately equal to 1.2020569 given by

$$\zeta(3) = \sum_{k=1}^{\infty} \frac{1}{k^3}.$$

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstApery()
ereal('1.2020569031595942854')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstApery()
1.20205690315959
```

2.8.9 Catalan's constant

property `ctx.catalan`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the Catalan constant. See also Wikipedia [1284], MathWorld [900], Mpmath [606].

Catalan's constant K = 0.91596559… is given by the infinite series

$$K = \sum_{k=0}^{\infty} \frac{(-1)^k}{(2k+1)^2}.$$

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstCatalan()
ereal('9.1596559417721901505E-1')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstCatalan()
0.915965594177219
```

2.8.10 Glaisher's constant

property ctx.**glaisher**

where ctx is math53, ctxboost or ctxflint.

Returns Glaisher's constant. See also Wikipedia [1282], MathWorld [906], Mpmath [613].

The constant is defined as $A = \exp(1/12 - \zeta'(-1))$ where $\zeta'(s)$ denotes the derivative of the Riemann zeta function.

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstGlaisher()
ereal('1.2824271291006226369')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstGlaisher()
1.28242712910062
```

2.8.11 Khinchin's constant

property ctx.**khinchin**

where ctx is math53, ctxboost or ctxflint.

Returns Khinchin's constant. See also Wikipedia [1289], MathWorld [908], Mpmath [618].

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstKhinchin()
ereal('2.6854520010653064454')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstKhinchin()
2.68545200106531
```

2.8.12 Imaginary One

property ctx.**onej**

where ctx is math53, ctxboost or ctxflint.

Returns the imaginary unit.

In extended precision (32 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstDegree()
ereal('1.7453292519943295769E-2')
```

In double precision (64 bit version of xlcalcnet)

```
>>> from xlcalcnet import ereal
>>> ereal.ConstDegree()
0.0174532925199433
```

CHAPTER

THREE

ELEMENTARY SCALAR FUNCTIONS (REAL AND COMPLEX)

The functions in this chapter comprise the usual elementary functions, as included in the C++ standard library, and a few specializations.

The source code for the C# tests in Visual Studio is divided by real and complex modules:

The source code for the C# tests in Visual Studio using real modules can be found online in the `XlCalcNet` repository or in the corresponding local `XlCalcNet` folder in the file B03a_RealElementaryFunctions.cs,

The source code for the C# tests in Visual Studio using complex modules can be found online in the `XlCalcNet` repository or in the corresponding local `XlCalcNet` folder in the file B03b_CplxElementaryFunctions.cs,

3.1 Complex components

3.1.1 Absolute value of a real or complex number

`ctx.abs`(x)

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the absolute value of x, $|x|$.

An example in Python

```
>>> from xlcalcnet import ecplx
>>> ecplx.Abs(0.5)
ecplx('5.2359877559829887307E-1')
>>> ecplx.Abs('0.1')
ecplx('5.351847902755998475 4E-1')
```

`ctx.fabs`(x)

where `ctx` is `math53`, `mathc53` or `ctxcpp`. This is an alias of `ctx.abs(x)`.

3.1.2 Sign of a real or complex number

`ctx.sign`(x)

where `ctx` is `math53`, `mathc53` or `ctxcpp`.

Returns the sign of x, defined as $\text{sign}(x) = x/|x|$ (with the special case $\text{sign}(0) = 0$):

See also: https://en.wikipedia.org/wiki/Sign_function

Note that the sign function is also defined for complex numbers, for which it gives the projection onto the unit circle:

An example in Python

```
>>> from xlcalcnet import ecplx
>>> ecplx.Sign(0.5)
ecplx('5.235987755982988730 7E-1')
>>> ecplx.Sign('0.1')
ecplx('5.351847902755998475 4E-1')
```

3.1.3 Real part of a real or complex number

`ctx.`**`real`**`(`x`)`

where `ctx` is `math53`, `mathc53` or `ctxcpp`.

Returns the real part of x, $\Re(x)$.

An example in Python

```
>>> from xlcalcnet import ecplx
>>> ecplx.Real(0.5)
ecplx('5.235987755982988730 7E-1')
>>> ecplx.Real('0.1')
ecplx('5.351847902755998475 4E-1')
```

3.1.4 Imaginary part of a real or complex number

`ctx.`**`imag`**`(`x`)`

where `ctx` is `math53`, `mathc53` or `ctxcpp`.

Returns the imaginary part of x, $\Im(x)$.

An example in Python

```
>>> from xlcalcnet import ecplx
>>> ecplx.Imaginary(0.5)
ecplx('5.235987755982988730 7E-1')
>>> ecplx.Imaginary('0.1')
ecplx('5.351847902755998475 4E-1')
```

3.1.5 Phase (or argument) of a real or complex number

`ctx.`**`phase`**`(`x`)`

where `ctx` is `math53`, `mathc53` or `ctxcpp`.

Computes the complex argument (phase) of x, defined as the signed angle between the positive real axis and x in the complex plane: The angle is defined to satisfy $-\pi < \arg(x) \leq \pi$ and with the sign convention that a nonnegative imaginary part results in a nonnegative argument.

An example in Python

```
>>> from xlcalcnet import ecplx
>>> ecplx.Phase(0.5)
ecplx('5.235987755982988730 7E-1')
>>> ecplx.Phase('0.1')
ecplx('5.351847902755998475 4E-1')
```

3.1.6 Conjugate of a real or complex number

`ctx.`**`conj`**`(`x`)`

where `ctx` is `math53`, `mathc53` or `ctxcpp`.

Returns the complex conjugate of x, $\overline{x}$.

An example in Python

```
>>> from xlcalcnet import ecplx
>>> ecplx.Conj(0.5)
ecplx('5.235987755982988730 7E-1')
>>> ecplx.Conj('0.1')
ecplx('5.351847902755998475 4E-1')
```

3.1.7 Polar representation of a real or complex number

`ctx.`**`polar`**`(`z`)`

where `ctx` is `math53`, `mathc53` or `ctxcpp`.

Returns the polar representation of the complex number z as a pair (r, ϕ) such that $z = re^{i\phi}$:

See also Mpmath [679].

An example in Python

```
>>> from xlcalcnet import ecplx
>>> ecplx.Polar(0.5)
ecplx('5.235987755982988730 7E-1')
>>> ecplx.Polar('0.1')
ecplx('5.351847902755998475 4E-1')
```

3.1.8 Rectangular coordinates calculated from the polar representation of a real or complex number

`ctx.`**`rect`**`(`r, *phi*`)`

where `ctx` is `math53`, `mathc53` or `ctxcpp`.

Returns the complex number represented by polar coordinates (r, ϕ):

See also Mpmath [671].

An example in Python

```
>>> from xlcalcnet import ecplx
>>> ecplx.Rect(0.5)
ecplx('5.235987755982988730 7E-1')
>>> ecplx.Rect('0.1')
ecplx('5.351847902755998475 4E-1')
```

3.2 Roots and quadratic, cubic, and quartic equations

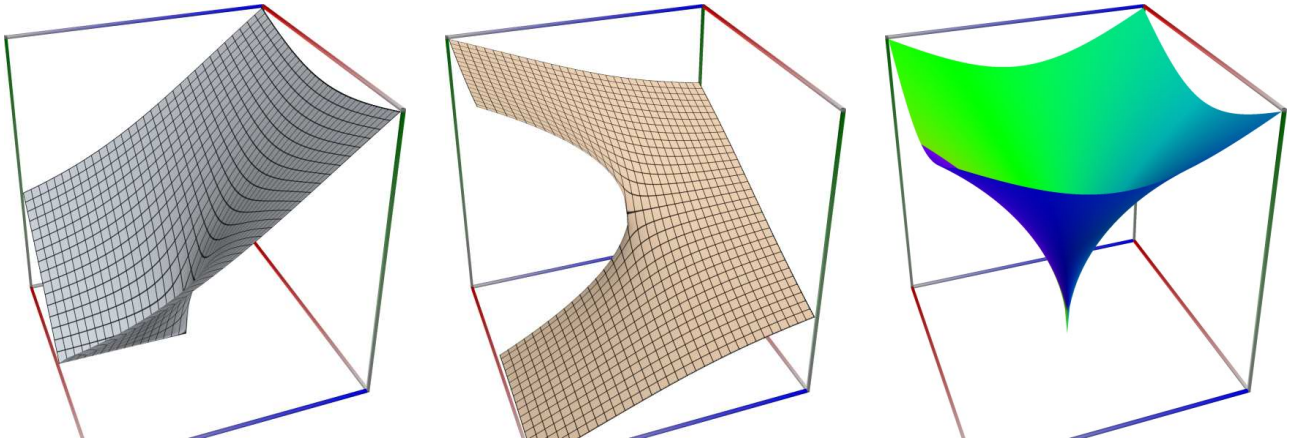
3.2.1 Square root, $\mathrm{sqrt}(x) = \sqrt{x}$

`ctx.sqrt(x)`

where `ctx` is `math53`, `mathc53`, `ctxcpp`, `ctxflint`.

Returns the principal square root of x, $\sqrt{x}$. See also Wikipedia [1248], MathWorld [859], Flint [747], Ehrhardt [297] (4.1.19), Mpmath [560].

For positive real numbers, the principal root is simply the positive square root. For arbitrary complex numbers, the principal square root is defined to satisfy $\sqrt{x} = \exp(\log(x)/2)$. The function thus has a branch cut along the negative half real axis.



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Sqrt(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Sqrt('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '10.7'
>>> \mathrm{d}x = dec.sqrt(x); mx = mpm.sqrt(x); ix = ipm.sqrt(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  3.2710854467592252121535649236034010853 26E+0
mpm:  3.2710854467592252121535649236034010853 26e+0
ipm:  3.2710854467592252121535649236034010853 26e+0 (7.019e-40%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '10.7'
>>> fx = fpm.sqrt(x); gx = gmp.sqrt(x); ax = apm.sqrt(x)
>>> mpm.show([fx, gx, ax])
fpm:  3.27108544675922E+00
gmp:  3.2710854467592252121535649236034010853 26E+00
apm:  3.2710854467592252121535649236034010853 26e+0 (7.019e-40%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '10.2 + 1.5E-2j'
>>> \mathrm{d}z = dec.sqrt(z); mz = mpm.sqrt(z); iz = ipm.sqrt(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 3.1937447478943743524E+0              + 2.34834045674587046 92E-3j
mpm: 3.1937447478943743524e+0              + 2.34834045674587046 92e-3j
ipm: 3.1937447478943743524e+0 (5.304e-20%) + 2.34834045674587046 92e-3 (2.113e-19%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '10.2 + 1.5E-2j'
>>> fz = fpm.sqrt(z); gz = gmp.sqrt(z); az = apm.sqrt(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 3.19374474789437E+00                  + 2.34834045674587E-03j
gmp: 3.1937447478943743524E+00             + 2.34834045674587046 92E-03j
apm: 3.1937447478943743524e+0 (1.061e-19%) + 2.34834045674587046 92e-3 (1.409e-19%)j
```

3.2.2 Reciprocal square root, $\mathrm{rsqrt}(x) = 1/\sqrt{x}$

`ctx.`**`rsqrt`**(x)

where `ctx` is `math53`, `mathc53`, `ctxcpp`, `ctxflint`.

Returns the reciprocal of the principal square root of x, $1/\sqrt{x}$. See also Wikipedia [1248], MathWorld [859], Flint [747], Ehrhardt [297] (4.1.19), Mpmath [560].

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Rsqrt(0.5)
ereal('5.23598775598298873 07E-1')
>>> ereal.Rsqrt('0.51')
ereal('5.35184790275599847 54E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '10.7'
>>> \mathrm{d}x = dec.RSqrt(x); mx = mpm.RSqrt(x); ix = ipm.RSqrt(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  3.2710854467592252121535649236034010853 26E+0
mpm:  3.2710854467592252121535649236034010853 26e+0
ipm:  3.2710854467592252121535649236034010853 26e+0 (7.019e-40%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '10.7'
>>> fx = fpm.RSqrt(x); gx = gmp.RSqrt(x); ax = apm.RSqrt(x)
>>> mpm.show([fx, gx, ax])
fpm:  3.27108544675922E+00
gmp:  3.2710854467592252121535649236034010853 26E+00
apm:  3.2710854467592252121535649236034010853 26e+0 (7.019e-40%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '10.2 + 1.5E-2j'
>>> \mathrm{d}z = dec.RSqrt(z); mz = mpm.RSqrt(z); iz = ipm.RSqrt(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 3.1937447478943743524E+0              + 2.34834045674587046 92E-3j
mpm: 3.1937447478943743524e+0              + 2.34834045674587046 92e-3j
ipm: 3.1937447478943743524e+0 (5.304e-20%) + 2.34834045674587046 92e-3 (2.113e-19%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '10.2 + 1.5E-2j'
>>> fz = fpm.RSqrt(z); gz = gmp.RSqrt(z); az = apm.RSqrt(z)
```

(continues on next page)

(continued from previous page)

```
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 3.19374474789437E+00                  + 2.34834045674587E-03j
gmp: 3.193744747894374 3524E+00            + 2.34834045674587 04692E-03j
apm: 3.193744747894374 3524e+0 (1.061e-19%) + 2.34834045674587 04692e-3 (1.409e-19%)j
```

3.2.3 Auxiliary function $\mathrm{sqrt1pm1}(x) = \sqrt{1+x} - 1$

`ctx.`**`sqrt1pm1`**`(`x`)`

where `ctx` is `math53`, `mathc53`, `ctxcpp` , `ctxboost` or `ctxflint`.

Returns $\sqrt{1+x} - 1$, accurate also for x near 0. See also Wikipedia [1248], MathWorld [859], BoostMath [92].

This is calculated as $\mathrm{sqrt1pm1}(v) = \mathrm{expm1}(\mathrm{logp1}(v)/2)$. See *log1p()* and *expm1()*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Sqrt1pm1(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Sqrt1pm1('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '1.0E-10'
>>> \mathrm{d}x = dec.sqrt1pm1(x); mx = mpm.sqrt1pm1(x); ix = ipm.sqrt1pm1(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  4.9999999998750000000062499999996093750 00E-11
mpm:  4.9999999998750000000062499999996093750 00e-11
ipm:  4.9999999998750000000062499999996095978 67e-11 (1.121e-32%)

>>> from xlcalcnet import mpm, fpm, gmp, apm

apm: 4.99999999987502812 50e-11 (1.972e-19%) + 7.49999999962500000 00e-13 (2.054e-19%)j
```

3.2.4 Cube root, $\mathrm{cbrt}(x) = \sqrt[3]{x}$

`ctx.cbrt(x)`

where `ctx` is `math53`, `mathc53`, `ctxcpp`, `ctxboost`, `ctxflint`.

Returns the cube root of x, $x^{1/3}$. See also Wikipedia [1235], MathWorld [844], BoostMath [97], Ehrhardt [297] (4.2.17), Mpmath [543].

This function is faster and more accurate than raising to a floating-point fraction.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Cbrt(0.5)
ereal('5.2359877559829887307E-1')
>>> ereal.Cbrt('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '10.7'
>>> \mathrm{d}x = dec.cbrt(x); mx = mpm.cbrt(x); ix = ipm.cbrt(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  2.2035754532216254713516735131427483239 63E+0
mpm:  2.2035754532216254713516735131427483239 63e+0
ipm:  2.2035754532216254713516735131427483239 63e+0 (1.042e-39%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '10.7'
>>> fx = fpm.cbrt(x); gx = gmp.cbrt(x); ax = apm.cbrt(x)
>>> mpm.show([fx, gx, ax])
fpm:  2.20357545322163E+00
gmp:  2.2035754532216254713516735131427483239 63E+00
apm:  2.2035754532216254713516735131427483239 63e+0 (1.042e-39%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '10.2 + 1.5E-2j'
>>> \mathrm{d}z = dec.cbrt(z); mz = mpm.cbrt(z); iz = ipm.cbrt(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 2.1687034063721566890E+0              + 1.0630892238793233640E-3j
mpm: 2.1687034063721566890e+0              + 1.0630892238793233640e-3j
ipm: 2.1687034063721566890e+0 (7.811e-20%) + 1.0630892238793233640e-3 (3.112e-19%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '10.2 + 1.5E-2j'
>>> fz = fpm.cbrt(z); gz = gmp.cbrt(z); az = apm.cbrt(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 2.16870340637216E+00                  + 1.06308922387932E-03j
gmp: 2.1687034063721566890E+00             + 1.0630892238793233640E-03j
apm: 2.1687034063721566890e+0 (7.811e-20%) + 1.0630892238793233640e-3 (2.334e-19%)j
```

Every nonzero complex number has three cube roots. This function returns the cube root defined by $\exp(\log(x)/3)$ where the principal branch of the natural logarithm is used. Note that this does not give a real cube root for negative real numbers:

```
>>> mp.pretty = True
>>> mp.cbrt(-1)
(0.5 + 0.866025403784439j)
```

If you want the real cube root for negative real numbers, use the function `cuberoot` instead.

3.2.5 Nth root, $\mathrm{nroot}(x, n) = \sqrt[n]{x}$

`ctx.root_si`(*x*, *n*, *k=0*)

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the nth root of x. For real negative x, n needs to be an odd integer for a real result. See also Wikipedia [1285], MathWorld [940], Flint [747], Flint [737], Ehrhardt [297] (4.2.47), Mpmath [622].

See also: https://dlmf.nist.gov/1.11#iv

The roots of $z^n = a + ib$ are

$$\sqrt[n]{R}\left(\cos\left(\frac{\alpha + 2k\pi}{n}\right) + i\sin\left(\frac{\alpha + 2k\pi}{n}\right)\right),$$

where $R = \sqrt{a^2 + b^2}$, $\alpha = \mathrm{ph}(a + ib)$, with the principal value phase, and $k = 0, 1, \ldots, n - 1$.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Nroot(0.5, 4)
ereal('5.235987755982988730 7E-1')
>>> ereal.Nroot('0.51', 4)
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '125'; n = '3'
>>> \mathrm{d}x = dec.nthroot(x, n); mx = mpm.nthroot(x, n); ix = ipm.nthroot(x, n)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  5.000000000000000000000000000000000000000E+0
mpm:  5.000000000000000000000000000000000000000e+0
ipm:  5.000000000000000000000000000000000000000e+0 (2.755e-39%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '125'; n = '3'
>>> fx = fpm.nthroot(x, n); gx = gmp.nthroot(x, n); ax = apm.nthroot(x, n)
>>> mpm.show([fx, gx, ax])
fpm:  5.00000000000000E+00
gmp:  5.000000000000000000000000000000000000000E+00
apm:  5.000000000000000000000000000000000000002e+0 (3.673e-39%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '20.2 + 1.5E-2j'; n = '3'
>>> \mathrm{d}z = dec.nthroot(z, n); mz = mpm.nthroot(z, n); iz = ipm.nthroot(z, n)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 2.723435848429670208 0E+0              + 6.741176741256368021 6E-4j
mpm: 2.723435848429670208 0e+0              + 6.741176741256368021 6e-4j
ipm: 2.723435848429670208 0e+0 (1.866e-19%) + 6.741176741256368021 6e-4 (4.295e-19%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '20.2 + 1.5E-2j'; n = '3'
>>> fz = fpm.nthroot(z, n); gz = gmp.nthroot(z, n); az = apm.nthroot(z, n)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 2.72343584842967E+00                   + 6.74117674125637E-04j
gmp: 2.723435848429670208 0E+00             + 6.741176741256368021 6E-04j
apm: 2.723435848429670208 1e+0 (4.354e-19%) + 6.741176741256368021 6e-4 (6.135e-19%)j
```

3.2.6 Unit root, unitroot(n)

`ctx.unitroot(`n`)`

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the nth root of z.

See also Wikipedia [1293], MathWorld [935], Mpmath [621].

> **Caution**
>
> This still needs to be implemented

An example in Python

```
>>> from xlcalcnet import ecplx
>>> ecplx.Unitroots(0.5)
ecplx('5.235987755982988730 7E-1')
>>> ecplx.Unitroots('0.1')
ecplx('5.351847902755998475 4E-1')
```

3.3 Exponential and related functions

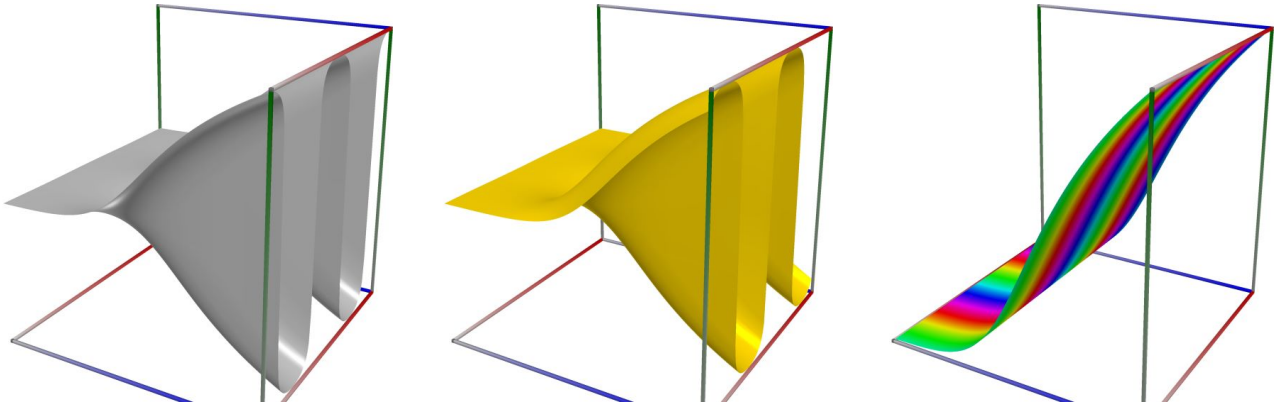
3.3.1 Exponential function $\exp(x) = e^x$

`ctx.exp(z)`

where `ctx` is `ctx_pm` (see *Python contexts* for details), `ctx53`, `ctxcpp`, `ctxflint` (see *.NET contexts* for details).

Returns $\exp(x)$, the exponential function of x. See also Wikipedia [1238], MathWorld [848], NIST [491], Ehrhardt [297] (4.2.34), Flint [740], Flint [730], Mpmath [548].

For complex numbers, the exponential function satisfies $\exp(x+iy) = e^x(\cos y + i \sin y)$.



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x+iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example with real input:

```
>>> from xlcalcnet import *
>>> x = -5.1; dps = 90
>>> for ctx in ctxlistreal: print(ctx.fmtname + ': ' + ctx.fmt(ctx.exp(x)))

```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder for Python (real input), Python (complex input), and C# (real or complex input).

3.3.2 Auxiliary function $\mathrm{expj}(x) = e^{ix}$

`ctx.expj(z)`

where `ctx` is `math53`, `mathc53`, `ctxcpp`, `ctxflint`.

Returns $e^{iz} = \cos(z) + i\sin(z)$. See also Wikipedia [1376], MathWorld [1021], Mpmath [707].

An example with real input:

```
>>> from xlcalcnet import *
>>> x = -5.1; dps = 50
>>> for ctx in gui.ctxlist_real: print(ctx.fmtname + ': ' + ctx.cplxctx.fmt(ctx.expj(x)))

```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder for Python (real input), Python (complex input), and C# (real or complex input).

3.3.3 Auxiliary function $\mathrm{expjpi}(x) = e^{i\pi x} = (-1)^x$

`ctx.expjpi(z)`

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns $e^{i\pi z} = \cos(\pi z) + i\sin(\pi z)$. See also Wikipedia [1376], MathWorld [1021], Flint [730], Mpmath [708].

Evaluation is accurate near zeros (see also *cospi()* and *sinpi()*):

An example with real input:

```
>>> from xlcalcnet import *
>>> x = -5.1; dps = 50
>>> for ctx in gui.ctxlist_real: print(ctx.fmtname + ': ' + ctx.cplxctx.fmt(ctx.expjpi(x)))

```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder for Python (real input), Python (complex input), and C# (real or complex input).

3.3.6 Auxiliary function $\mathrm{expm1}(x) = e^x - 1$

`ctx.`**`expm1`**`(`x`)`

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns $\mathrm{expm1}(x) = \exp(x) - 1 = e^x - 1$, computed accurately also for small x. See also Wikipedia [1237], MathWorld [848], NIST [491], BoostMath [75], Ehrhardt [297] (4.2.37), Flint [740], Flint [730], Mpmath [549].

An example with real input:

```
>>> from xlcalcnet import *
>>> x = -5.1; dps = 90
>>> for ctx in gui.ctxlist_real: print(ctx.fmtname + ': ' + ctx.fmt(ctx.expm1(x)))

```

The above and additional examples can be found online in the `DataXlCalcNet` repository or in the corresponding local `DataXlCalcNet` folder for Python (real input), Python (complex input), and C# (real or complex input).

3.4 Logarithms and related functions

3.4.1 Natural logarithm $\log(x)$

`ctx.log(`x`)`

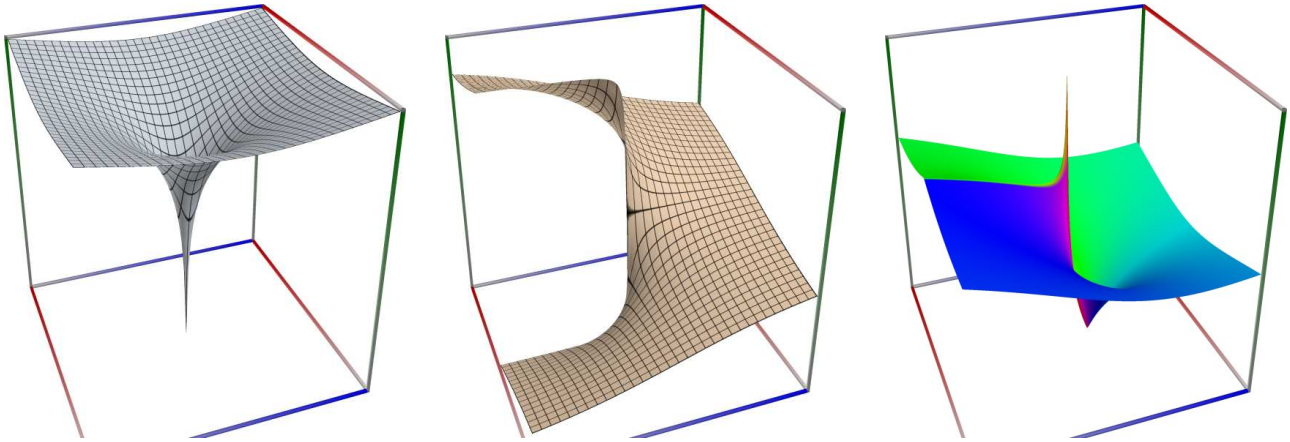
where `ctx` is `math53`, `mathc53`, `ctxcpp`, `ctxflint`.

Returns the natural logarithm of x, $\log(x) = \log(x)$. See also Wikipedia [1234], MathWorld [854], NIST [492], Ehrhardt [297] (4.2.41), Flint [740], Flint [730], Mpmath [556].

$$\log(x) = \int_1^x \frac{1}{t}\,\mathrm{d}t.$$

If x is less than 1, then this area is considered to be negative.

The principal branch of the complex logarithm is used, meaning that $\Im(\log(z)) = -\pi < \arg(z) \leq \pi$.



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \leq x \leq 6$ (blue axis), $-6 \leq y \leq 6$ (red axis), $-10 \leq z \leq 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Log(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Log('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '1.0E-100'
>>> \mathrm{d}x = dec.Log(x); mx = mpm.Log(x); ix = ipm.Log(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  -2.3025850929940456840179914546843642076 01E+2
mpm:  -2.3025850929940456840179914546843642076 01e+2
ipm:  -2.3025850929940456840179914546843642076 01e+2 (-6.381e-40%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '1.0E-100'
>>> fx = fpm.Log(x); gx = gmp.Log(x); ax = apm.Log(x)
>>> mpm.show([fx, gx, ax])
fpm:  -2.30258509299405E+02
gmp:  -2.3025850929940456840179914546843642076 01E+02
apm:  -2.3025850929940456840179914546843642076 01e+2 (-1.276e-39%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '1.0E-100 + 1.57079632679489j'
>>> \mathrm{d}z = dec.Log(z); mz = mpm.Log(z); iz = ipm.Log(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 4.5158270528945065079E-1              + 1.5707963267948966192E+0j
mpm: 4.5158270528945065079e-1              + 1.5707963267948966192e+0j
ipm: 4.5158270528945065079e-1 (1.876e-19%) + 1.5707963267948966192e+0 (5.392e-20%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '1.0E-100 + 1.57079632679489j'
>>> fz = fpm.Log(z); gz = gmp.Log(z); az = apm.Log(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 4.51582705289451E-01                  + 1.57079632679490E+00j
gmp: 4.5158270528945065079E-01             + 1.5707963267948966192E+00j
apm: 4.5158270528945065079e-1 (1.407e-19%) + 1.5707963267948966192e+0 (1.078e-19%)j
```

3.4.2 Logarithm with base 10, $\log10(x) = \log_{10}(x)$

`ctx.log10(`x`)`

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the base-10 logarithm of x, $\log_{10}(x) = \log(x)/\log(10)$. See also. Wikipedia [1232], MathWorld [843], NIST [492], Ehrhardt [297] (4.2.44), Mpmath [554].

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Log10(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Log10('0.51')
ereal('5.3518479027559984754E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '1.0E-100'
>>> \mathrm{d}x = dec.log10(x); mx = mpm.log10(x); ix = ipm.log10(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  -1.000000000000000000000000000000000000000E+2
mpm:  -1.000000000000000000000000000000000000000e+2
ipm:  -1.000000000000000000000000000000000000000e+2 (-1.469e-39%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '1.0E-100'
>>> fx = fpm.log10(x); gx = gmp.log10(x); ax = apm.log10(x)
>>> mpm.show([fx, gx, ax])
fpm:  -1.00000000000000E+02
gmp:  -1.000000000000000000000000000000000000000E+02
apm:  -1.000000000000000000000000000000000000000e+2 (-1.469e-39%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '1.0E-100 + 1.57079632679489j'
>>> \mathrm{d}z = dec.log10(z); mz = mpm.log10(z); iz = ipm.log10(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 1.9611987703015082905E-1              + 6.8218817692092067374E-1j
mpm: 1.9611987703015082905e-1              + 6.8218817692092067374e-1j
ipm: 1.9611987703015082905e-1 (1.62e-19%) + 6.8218817692092067374e-1 (6.208e-20%)j

apm: 1.961198770301508290 5e-1 (2.159e-19%) + 6.821881769209206737 4e-1 (6.208e-20%)j
```

3.4.3 Logarithm with base 2, $\log2(x) = \log_2(x)$

ctx.log2(x)

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the base-2 logarithm of x, $\log_2(x) = \log(x)/\log(2)$. See also Wikipedia :cite:p: $WikipediaFun19$, MathWorld [842], NIST [492].

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Log2(0.5)
ereal('5.2359877559829887307E-1')
>>> ereal.Log2('0.51')
ereal('5.3518479027559984754E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '1.0E-100'
>>> \mathrm{d}x = dec.log2(x); mx = mpm.log2(x); ix = ipm.log2(x)

apm: 1.961198770301508290 5e-1 (2.159e-19%) + 6.821881769209206737 4e-1 (6.208e-20%)j
```

3.4.4 Logarithm with base b, $\mathrm{logbase}(x, b) = \log_b(x)$

`ctx.logbase`(x, b)

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the base-b logarithm of x, $\log_b(x) = \log(x)/\log(b)$. See also Wikipedia [1243], Wikipedia [1234], MathWorld [853], NIST [492], Ehrhardt [297] (4.2.45), Flint [740], Flint [730], Mpmath [555].

The principal branch of the complex logarithm is used, meaning that $\Im(\log(z)) = -\pi < \arg(z) \leq \pi$.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Logb(0.5, 2)
ereal('5.2359877559829887307E-1')
>>> ereal.Logb('0.51', 2)
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '3'; b = 2
>>> \mathrm{d}x = dec.logb(x, b); mx = mpm.logb(x, b); ix = ipm.logb(x, b)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  1.5849625007211561814537389439478165087 60E+0
mpm:  1.5849625007211561814537389439478165087 60e+0
ipm:  1.5849625007211561814537389439478165087 60e+0 (7.243e-40%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '3'
>>> fx = fpm.logb(x, b); gx = gmp.logb(x, b); ax = apm.logb(x, b)
>>> mpm.show([fx, gx, ax])
fpm:  1.58496250072116E+00
gmp:  1.5849625007211561814537389439478165087 60E+00
apm:  1.5849625007211561814537389439478165087 60e+0 (4.346e-39%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '3 + 1.570796326794 89j'; b = 2
>>> \mathrm{d}z = dec.logb(z, b); mz = mpm.logb(z, b); iz = ipm.logb(z, b)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 1.7597332799736771780E+0              + 6.9588093355781665181E-1j

apm: 1.7597332799736771780e+0 (4.813e-19%) + 6.9588093355781665181e-1 (5.477e-19%)j
```

3.4.5 Auxiliary function $\mathrm{log1p}(x) = \log(x + 1)$

`ctx.log1p`(x)

where `ctx` is `math53`, `mathc53`, `ctxcpp`, `ctxflint`.

Returns $\log(1 + x) = \log(1 + x)$, accurately for small x. See also Wikipedia [1243], Wikipedia [1242], MathWorld [853], NIST [492], BoostMath [107], Ehrhardt [297] (4.2.34), Flint [740], Flint [730], Mpmath [553].

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Log1p(0.5)
ereal('5.23598775598298873077E-1')
>>> ereal.Log1p('0.51')
ereal('5.35184790275599847547E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '1.0E-10'
>>> \mathrm{d}x = dec.log1p(x); mx = mpm.log1p(x); ix = ipm.log1p(x)

```

3.5 Power functions

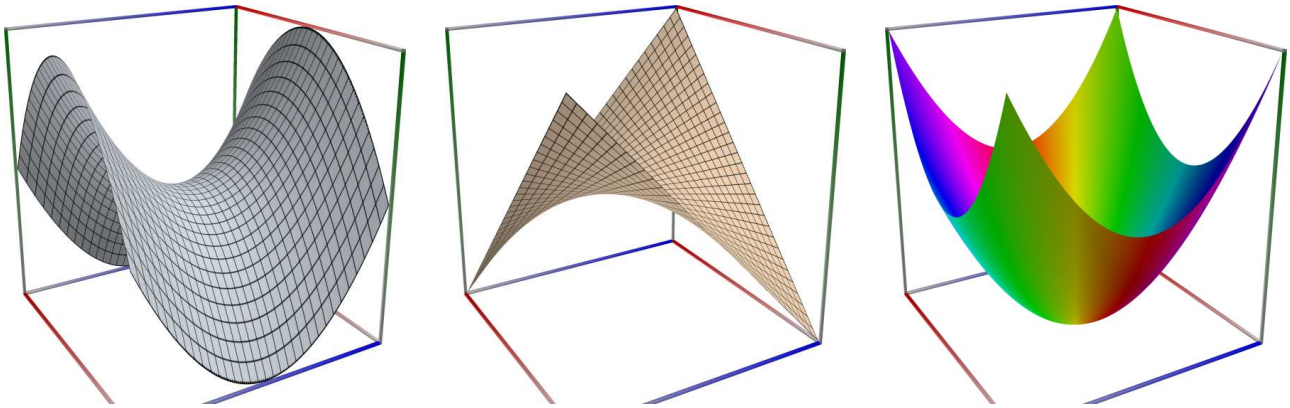
3.5.1 Square, x^2

`ctx.sqr`(x)

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the square function of x, x^2. See also Wikipedia [1247], MathWorld [858], Ehrhardt [297] (4.1.18).

Returns the square function of x, x^2. See also Wikipedia [1247], MathWorld [858], Ehrhardt [297] (4.1.18).



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \leq x \leq 6$ (blue axis), $-6 \leq y \leq 6$ (red axis), $-10 \leq z \leq 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

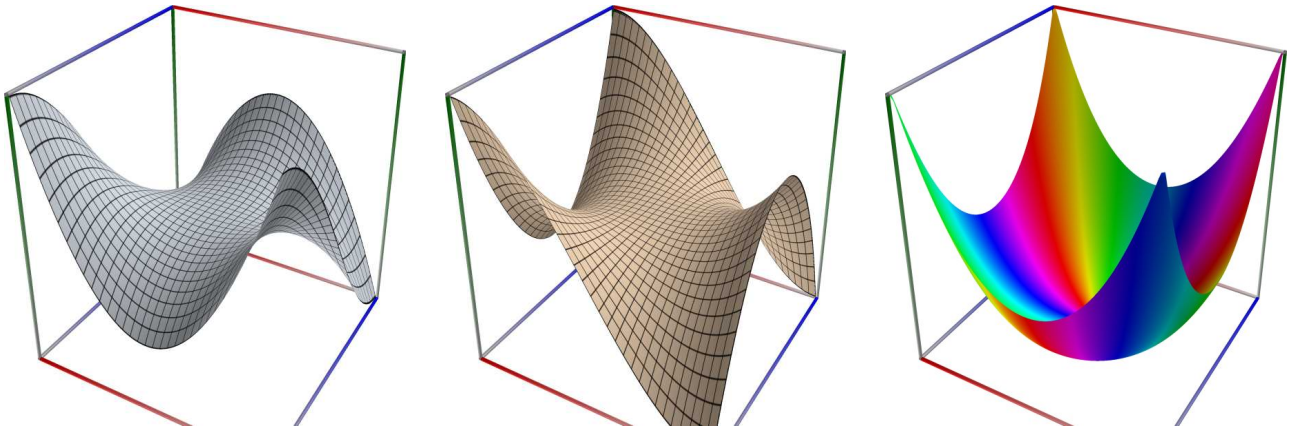
```
>>> from xlcalcnet import ereal
>>> ereal.Square(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Square('0.51')
ereal('5.351847902755998475 4E-1')
```

3.5.2 Cube, x^3

`ctx.cube`(x)

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the cube function of x, x^3. See also Wikipedia [1247], MathWorld [858], Ehrhardt [297] (4.1.18).



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Square(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Square('0.51')
ereal('5.351847902755998475 4E-1')
```

3.5.3 Auxiliary function $\mathrm{powi}(x, n) = x^n$

`ctx.pow_si`(x, n)

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Note: ctx.intpower(x, n)

Returns the integer power function of x, x^n. See also Wikipedia [1247], MathWorld [858].

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Intpower(0.5, 2)
ereal('5.235987755982988730 7E-1')
>>> ereal.Intpower('0.51', 2)
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '10.5'
>>> \mathrm{d}x = dec.square(x); mx = mpm.square(x); ix = ipm.square(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  1.1025000000000000000000000000000000000E+2
mpm:  1.1025000000000000000000000000000000000e+2
ipm:  1.1025000000000000000000000000000000000e+2 (0.0%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '10.5'
>>> fx = fpm.square(x); gx = gmp.square(x); ax = apm.square(x)
>>> mpm.show([fx, gx, ax])
fpm:  1.10250000000000E+02
gmp:  1.1025000000000000000000000000000000000E+02
apm:  1.1025000000000000000000000000000000000e+2 (0.0%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '10.2 + 1.5E-2j'
>>> \mathrm{d}z = dec.square(z); mz = mpm.square(z); iz = ipm.square(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 1.0403977500000000000E+2              + 3.0600000000000000000E-1j
mpm: 1.0403977500000000000e+2              + 3.0600000000000000000e-1j
ipm: 1.0403977500000000000e+2 (2.084e-19%) + 3.0600000000000000000e-1 (2.076e-19%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '10.2 + 1.5E-2j'
>>> fz = fpm.square(z); gz = gmp.square(z); az = apm.square(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 1.04039775000000E+02                  + 3.06000000000000E-01j
gmp: 1.0403977500000000000E+2              + 3.0600000000000000000E-01j
apm: 1.0403977500000000000e+2 (2.084e-19%) + 3.0600000000000000000e-1 (2.076e-19%)j
```

3.5.4 Auxiliary function $\mathrm{hypot}(x, y) = \sqrt{x^2 + y^2}$

`ctx.hypot`(x, y)

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns $\mathrm{hypot}(x, y) = \sqrt{x^2 + y^2}$ in a way which avoids undue underflow and overflow. See also Wikipedia [1288], BoostMath [122], Mpmath [616].

The function is even and symmetric in x and y, so we assume $x, y > 0$ and $x > y$ (we can permute the arguments if this is not the case). Then the result is calculated as:

$$\mathrm{hypot}(x, y) = x\sqrt{1 + \left(\frac{y}{x}\right)^2}$$

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Hypot(0.5, 2)
ereal('5.2359877559829887307E-1')
>>> ereal.Hypot(0.5, 2)
ereal('5.3518479027559984754E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; a = '20.4'; b = '10.4'
>>> \mathrm{d}x = dec.hypot(a, b); mx = mpm.hypot(a, b); ix = ipm.hypot(a, b)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  2.2898034850178737554414370473513406543 58E+1
mpm:  2.2898034850178737554414370473513406543 58e+1
ipm:  2.2898034850178737554414370473513406543 58e+1 (2.406e-39%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; a = '20.4'; b = '10.4'
>>> fx = fpm.hypot(a, b); gx = gmp.hypot(a, b); ax = apm.hypot(a, b)
>>> mpm.show([fx, gx, ax])
fpm:  2.28980348501787E+01
gmp:  2.2898034850178737554414370473513406543 58E+01
apm:  2.2898034850178737554414370473513406543 58e+1 (2.326e-38%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; a = '20.2 + 1.5E+2j'; b = '10.7 + 2.3E+1j'
>>> \mathrm{d}z = dec.hypot(a, b); mz = mpm.hypot(a, b); iz = ipm.hypot(a, b)

apm: 2.1614348471624799140e+1 (2.508e-18%) + 1.5157061080517169075e+2 (3.29e-18%)j
```

3.5.5 Power function, $\mathrm{pow}(x, y) = x^y$

`ctx.pow`(x, y)

where `ctx` is `math53`, `mathc53`, `ctxcpp`, `ctxflint`.

Returns $x^y = \exp(y \log(x))$. See also Wikipedia [1252], Wikipedia [1239], MathWorld [855], NIST [490], Ehrhardt [297] (4.2.34), Flint [747], Flint [737], Mpmath [557].

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Pow(0.5, 3)
ereal('5.235987755982988730 7E-1')
>>> ereal.Pow('0.51', 3)
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; a = '20.4'; b = '10.4'
>>> \mathrm{d}x = dec.power(a, b); mx = mpm.power(a, b); ix = ipm.power(a, b)
>>> mpm.show([\mathrm{d}x, mx, ix])

```

3.5.6 Auxiliary function, $\mathrm{powm1}(x, y) = x^y - 1$

`ctx.powm1`(a, b)

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns $a^b - 1$, computed accurately also when a^b is very close to 1. This is calculated as $\mathrm{powm1}(a, b) = \mathrm{expm1}(b \log(a))$. See also Wikipedia [1239], MathWorld [855], NIST [490], BoostMath [91], Mpmath [620].

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Powm1(0.5, 3)
ereal('5.235987755982988730 7E-1')
>>> ereal.Powm1(0.5, 3)
ereal('5.351847902755998475 4E-1')
```

From mpmath:

```
>>> from xlcalcnet import mp
>>> mp.dps = 15; mp.pretty = True
>>> power(0.99999995, 1e-10) - 1
0.0
>>> powm1(0.99999995, 1e-10)
-5.00000012791934e-18
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; a = '0.99999995'; b = '1e-10'
>>> \mathrm{d}x = dec.powm1(a, b); mx = mpm.powm1(a, b); ix = ipm.powm1(a, b)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  -5.0000001250000041541668222916728880419 26E-18
mpm:  -5.0000001250000041541668222916728879195 13e-18
ipm:  -5.0000001250000041541668222916728884934 85e-18 (-1.148e-32%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; a = '0.99999995'; b = '1e-10'

```

3.5.7 Auxiliary function, $\mathrm{pow1p}(x, y) = (1 + x)^y$

`ctx.pow1p`(x, y)

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns $(1 + x)^y, x > -1$, with dbl2 arithmetic for critical values.

Returns $(1 + x)^y$. This is calculated as $\mathrm{pow1p}(x, y) = \exp(y\mathrm{logp1}(x))$.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Pow1p(0.5, 3)
ereal('5.2359877559829887307E-1')
>>> ereal.Pow1p(0.5, 3)
ereal('5.3518479027559984754E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; a = '0.000005'; b = '1e-5'

apm: 1.0000000000499998750e+0 (1.694e-19%) + 1.1649970500682080027e-15 (5.166e-19%)j
```

3.5.8 Auxiliary function, $\mathrm{pow1pm1}(x, y) = (1 + x)^y - 1$

`ctx.pow1pm1`(x, y)

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns $(1 + x)^y - 1, x > -1$, special code for small x, y.

This is calculated as $\mathrm{pow1pm1}(x, y) = \mathrm{expm1}(y \cdot \mathrm{logp1}(x))$.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Sqrt(0.5)
ereal('5.23598775598298873077-1')
>>> ereal.Sqrt('0.51')
ereal('5.35184790275599847547-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; a = '0.000005'; b = '1e-5'
>>> \mathrm{d}x = dec.pow1pm1(a, b); mx = mpm.pow1pm1(a, b); ix = ipm.pow1pm1(a, b)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  4.9999875001666658854222395520835211422 82E-11
mpm:  4.9999875001666658854222395520835211422 82e-11
ipm:  4.9999875001666658854222395520835211422 75e-11 (2.272e-37%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; a = '0.000005'; b = '1e-5'
```

(continues on next page)

(continued from previous page)

```
>>> fx = fpm.pow1pm1(a, b); gx = gmp.pow1pm1(a, b); ax = apm.pow1pm1(a, b)

```

3.6 Trigonometric functions, in radians

For a general introduction to trigonometric functions, see Wikipedia [1249], NIST [493].

3.6.1 Sine, $\sin(x)$

`ctx.sin(x)`

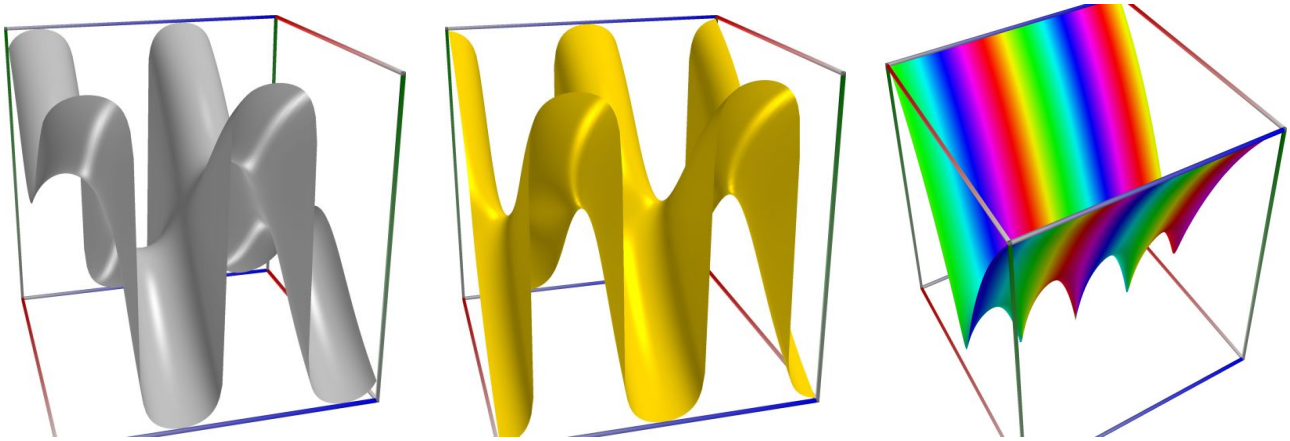
where `ctx` is `ctx_pm` (see *Python contexts* for details), `ctx53`, `ctxcpp`, `ctxflint` (see *.NET contexts* for details). The corresponding `ctx` python lists are `ctxlistreal` and `ctxlistcplx`.

Returns the sine of x, $\sin(x)$. See also Wikipedia [1246], MathWorld [876], NIST [493], Ehrhardt [297] (4.2.55), Flint [748], Flint [738], Mpmath [559].

The sine can be defined as $\sin(x) = x - \frac{x^3}{3!} + \frac{x^5}{5!} - \frac{x^7}{7!} + \cdots = \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n+1)!} x^{2n+1}$.

The complex sine can be expressed in terms of related real functions:

$$\sin(z) = \sin(x+iy) = \frac{e^{iz} - e^{-iz}}{2i} = \sin(x)\cosh(y) + i\cos(x)\sinh(y).$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x+iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example with real input:

```
>>> from xlcalcnet import *
>>> x = -5.1; dps = 90
>>> for ctx in ctxlistreal: print(ctx.fmtname + ': ' + ctx.fmt(ctx.sin(x)))

```

3.6.2 Cosine, $\cos(x)$

`ctx.cos(`x`)`

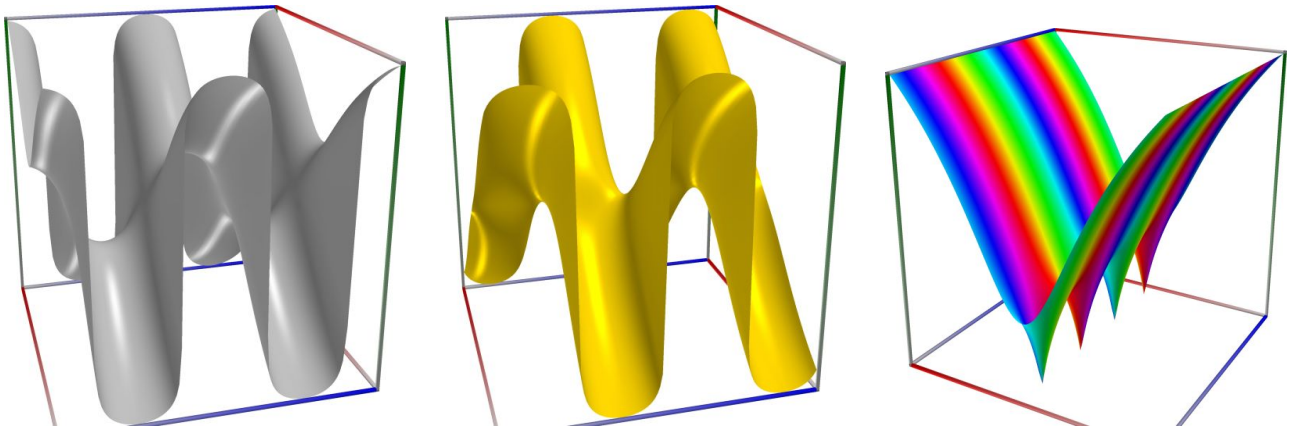
where `ctx` is `math53`, `mathc53`, `ctxcpp`, `ctxflint`.

Returns the cosine of x, $\cos(x)$. See also Wikipedia [1249], MathWorld [861], NIST [493], Ehrhardt [297] (4.2.19), Flint [748], Flint [738], Mpmath [542].

The cosine can be defined as $\cos(x) = 1 - \frac{x^2}{2!} + \frac{x^4}{4!} - \frac{x^6}{6!} + \cdots = \sum_{n=0}^{\infty} \frac{(-1)^n}{(2n)!} x^{2n}$.

The complex cosine can be expressed in terms of related real functions:

$$\cos(z) = \cos(x + iy) = \frac{e^{ix} + e^{-ix}}{2} = \cos(x)\cosh(y) - i\sin(x)\sinh(y).$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Cos(0.5)
ereal('5.2359877559829887307E-1')
>>> ereal.Cos('0.51')
ereal('5.3518479027559984754E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '1.57079632679489'
>>> \mathrm{d}x = dec.cos(x); mx = mpm.cos(x); ix = ipm.cos(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  6.619231321691639751442098584651351473054E-15
mpm:  6.619231321691639751442098575708073666164e-15
ipm:  6.619231321691639751442098587187510685913e-15 (1.734e-25%)
```

(continues on next page)

(continued from previous page)

```
>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '1.57079632679489'
>>> fx = fpm.cos(x); gx = gmp.cos(x); ax = apm.cos(x)
>>> mpm.show([fx, gx, ax])
fpm:  6.72257048770831E-15
gmp:  6.619231321691639751442098575708073666164E-15
apm:  6.619231321691639751442098584676383837843e-15 (1.768e-25%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '3.14159265358979 + 1.5E+2j'
>>> \mathrm{d}z = dec.cos(z); mz = mpm.cos(z); iz = ipm.cos(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: -6.9685479033318984866E+64              - 2.2567382063567230055E+50j
mpm: -6.9685479033318984866e+64              - 2.2567375654278714043e+50j
ipm: -6.9685479033318984866e+64 (-6.4e-20%) - 2.2567387459458051327e+50 (-5.231e-5%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '3.14159265358979 + 1.5E+2j'
>>> fz = fpm.cos(z); gz = gmp.cos(z); az = apm.cos(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: -6.96854790333190E+64                   - 2.25159995138029E+50j
gmp: -6.9685479033318984866E+64              - 2.2567375654278714043E+50j
apm: -6.9685479033318984866e+64 (-6.4e-20%) - 2.2567382294692091265e+50 (-5.406e-5%)j
```

3.6.3 Tangent, $\tan(x)$

`ctx.tan(`x`)`

where `ctx` is `math53`, `mathc53`, `ctxcpp`, `ctxflint`.

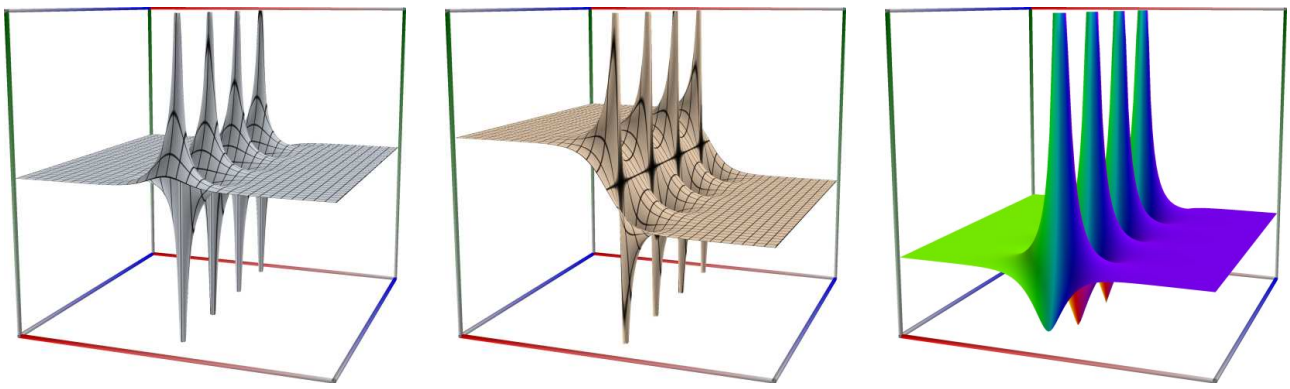
Returns the tangent of x, $\tan(x)$. See also Wikipedia [1249], MathWorld [877], NIST [493], Ehrhardt [297] (4.2.61), Flint [748], Flint [738], Mpmath [582].

The tangent can be defined in terms of related functions as $\tan(x) = \dfrac{\sin(x)}{\cos(x)}$.

The tangent function is singular at $x = (n + 1/2)\pi$, but `tan(x)` always returns a finite result since $(n + 1/2)\pi$ cannot be represented exactly using floating-point arithmetic.

The complex tangent can be expressed in terms of related real functions:

$$\tan(z) = \tan(x + iy) = \frac{\sin(z)}{\cos(z)} = \frac{\sin(2x) + i\sinh(2y)}{\cos(2x) + i\cosh(2y)}$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Tan(0.5)
ereal('5.2359877559829887307E-1')
>>> ereal.Tan('0.51')
ereal('5.3518479027559984754E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '1.57079632679489'
>>> \mathrm{d}x = dec.tan(x); mx = mpm.tan(x); ix = ipm.tan(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  1.5107494381151731974847433363776779549 45E+14
mpm:  1.5107494381151731974847433338418593648 45e+14
ipm:  1.5107494381151731974847433357988341406 73e+14 (1.734e-25%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '1.57079632679489'
>>> fx = fpm.tan(x); gx = gmp.tan(x); ax = apm.tan(x)
>>> mpm.show([fx, gx, ax])
fpm:  1.48752623989354E+14

```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '1.57079632679489 + 0.001j'
>>> \mathrm{d}z = dec.tan(z); mz = mpm.tan(z); iz = ipm.tan(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 6.6192291152816404696E-9            + 1.0000003333333111111E+3j
mpm: 6.6192285676675710077e-9            + 1.0000003333333111111e+3j
ipm: 6.6192294147002359176e-9 (1.28e-5%) + 1.0000003333333111111e+3 (6.505e-19%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '1.57079632679489 + 0.001j'
>>> fz = fpm.tan(z); gz = gmp.tan(z); az = apm.tan(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 6.72256824685193E-09                + 1.00000033333331E+03j
gmp: 6.6192285676675710076E-09           + 1.0000003333333111111E+03j
apm: 6.6192291235327573548e-9 (1.32e-5%) + 1.0000003333333111111e+3 (1.301e-19%)j
```

From mpmath:

```
>>> from xlcalcnet import  mp
>>> iv.tan([0,2])  # Interval includes a singularity
[-inf, +inf]
```

3.6.4 Cotangent, $\cot(x)$

`ctx.cot(`x`)`

where `ctx` is `math53`, `mathc53`, `ctxcpp`, `ctxflint`.

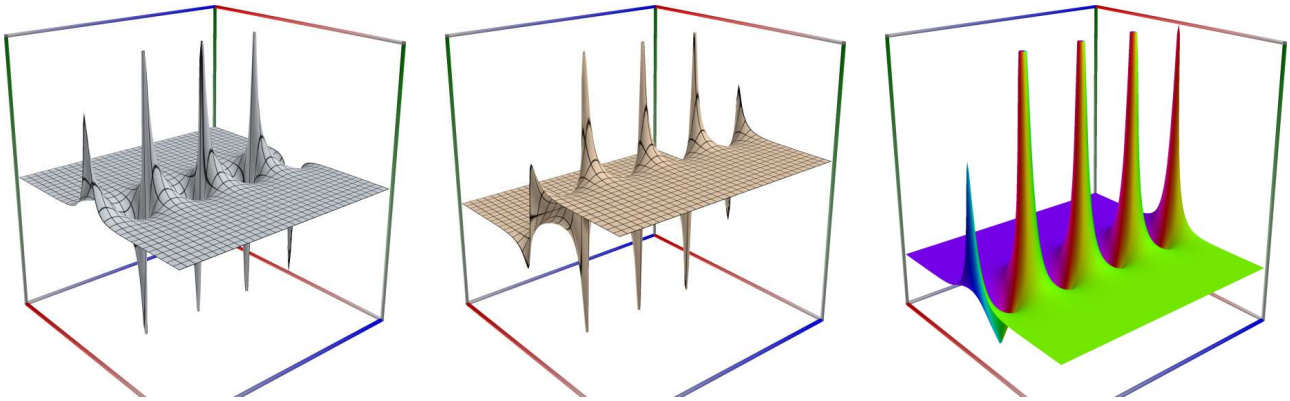
Returns the cotangent of x, $\cot(x)$. See also Wikipedia [1249], MathWorld [862], NIST [493], Ehrhardt [297] (4.2.21), Flint [748], Flint [738], Mpmath [562].

The cotangent can be expressed in terms of related functions as $\cot(x) = \dfrac{\cos(x)}{\sin(x)}$.

This cotangent function is singular at $x = n\pi$, but with the exception of the point $x = 0$, `cot(x)` returns a finite result since $n\pi$ cannot be represented exactly using floating-point arithmetic.

The complex cotangent can be expressed in terms of related real functions:

$$\cot(z) = \cot(x + iy) = \frac{\cos(z)}{\sin(z)} = \frac{\cos(2x) + i\cosh(2y)}{\sin(2x) + i\sinh(2y)}$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Cot(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Cot('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '1.57079632679489'
>>> \mathrm{d}x = dec.cot(x); mx = mpm.cot(x); ix = ipm.cot(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  6.619231321691639751442098584796359712623E-15
mpm:  6.619231321691639751442098575853081905733e-15

```

3.6.5 Cosecant, $\csc(x)$

`ctx.csc(`x`)`

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

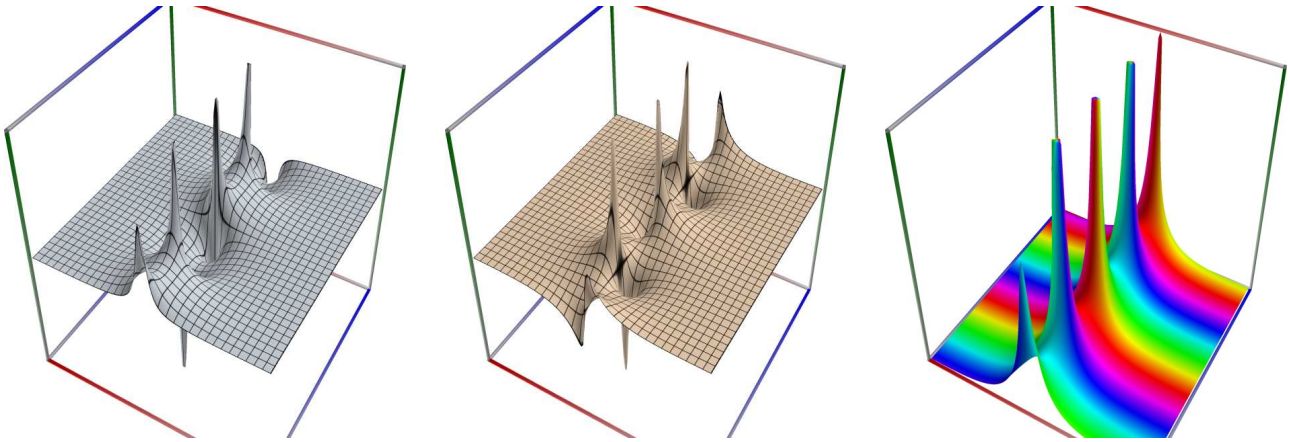
Returns the cosecant of x, $\csc(x)$. See also Wikipedia [1249], MathWorld [860], NIST [493], Ehrhardt [297] (4.2.23), Flint [748], Flint [738], Mpmath [561].

The cosecant can be expressed in terms of related functions as $\csc(x) = \dfrac{1}{\sin(x)}$.

The cosecant function is singular at $x = n\pi$, but with the exception of the point $x = 0$, `csc(x)` returns a finite result since $n\pi$ cannot be represented exactly using floating-point arithmetic.

The complex cosecant can be expressed in terms of related real functions:

$$\csc(z) = \csc(x + iy) = \frac{1}{\sin(z)} = \frac{2i}{e^{ix} - e^{-ix}} = \frac{1}{\sin(x)\cosh(y) + i\cos(x)\sinh(y)}.$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Csc(0.5)
ereal('5.2359877559829887307E-1')
>>> ereal.Csc('0.51')
ereal('5.3518479027559984754E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '3.14159265358979'
>>> \mathrm{d}x = dec.csc(x); mx = mpm.csc(x); ix = ipm.csc(x)
```

(continues on next page)

(continued from previous page)

```

```

3.6.6 Secant, $\sec(x)$

`ctx.sec(`x`)`

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

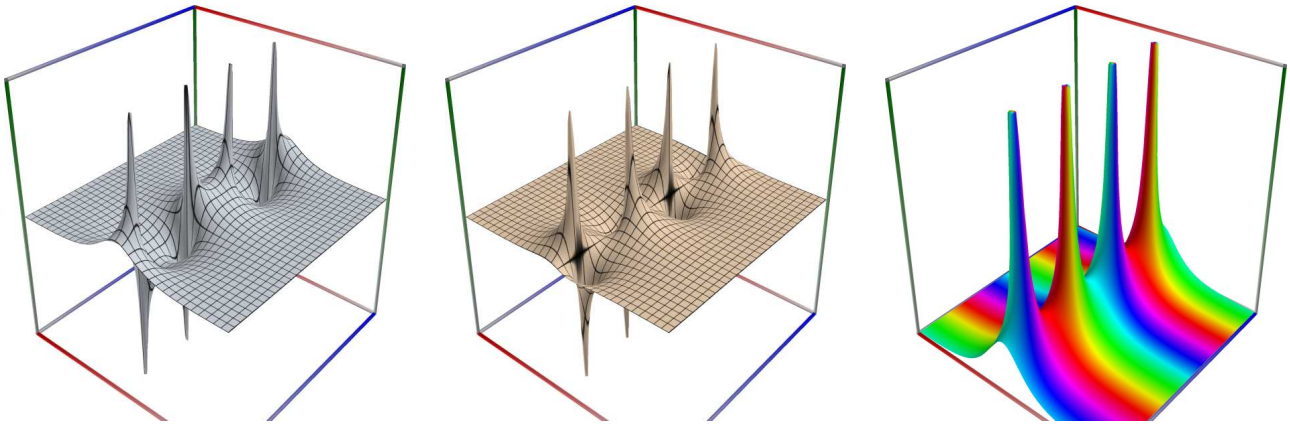
Returns the secant of x, $\sec(x)$. See also Wikipedia [1249], MathWorld [875], NIST [493], Ehrhardt [297] (4.2.53), Flint [748], Flint [738], Mpmath [581].

The secant can be expressed in terms of related functions as $\sec(x) = \dfrac{1}{\cos(x)}$.

The secant function is singular at $x = (n + 1/2)\pi$, but `sec(x)` always returns a finite result since $(n + 1/2)\pi$ cannot be represented exactly using floating-point arithmetic.

The complex secant can be expressed in terms of related real functions:

$$\sec(z) = \sec(x + iy) = \frac{1}{\cos(z)} = \frac{2}{e^{ix} + e^{-ix}} = \frac{1}{\cos(x)\cosh(y) - i\sin(x)\sinh(y)}.$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \leq x \leq 6$ (blue axis), $-6 \leq y \leq 6$ (red axis), $-10 \leq z \leq 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Sec(0.5)
ereal('5.2359877559829887307E-1')
>>> ereal.Sec('0.51')
ereal('5.3518479027559984754E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '1.57079632679489'
>>> \mathrm{d}x = dec.sec(x); mx = mpm.sec(x); ix = ipm.sec(x)

apm: -1.4350191946328820840e-65 (-5.605e-20%) + 4.6472561019516306473e-80 (5.401e-5%)j
```

3.6.7 Cardinal sine, $\mathrm{sinc}(x)$

`ctx.sinc`(x)

where `ctx` is `math53`, `mathc53`, `ctxcpp`, `ctxflint`.

Returns the cardinal sine of x. See also Wikipedia [1294], MathWorld [936], BoostMath [127], Flint [748], Flint [738], Mpmath [605].

`sinc(x)` computes the unnormalized sinc function, defined as $\mathrm{sinc}(x) = \begin{cases} \sin(x)/x, & \text{if } x \neq 0 \\ 1, & \text{if } x = 0. \end{cases}$

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Sinc(0.5)
ereal('5.235987755982988730E-1')
>>> ereal.Sinc('0.51')
ereal('5.351847902755998475E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '0.0000001'
>>> \mathrm{d}x = dec.sinc(x); mx = mpm.sinc(x); ix = ipm.sinc(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  9.9999999999999833333333333333341666666667E-1
mpm:  9.9999999999999833333333333333341666666667e-1
ipm:  9.9999999999999833333333333333341666666667e-1 (2.87e-39%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '0.0000001'
>>> fx = fpm.sinc(x); gx = gmp.sinc(x); ax = apm.sinc(x)
>>> mpm.show([fx, gx, ax])
fpm:  9.99999999999998E-01
gmp:  9.9999999999999833333333333333341666666667E-01
apm:  9.9999999999999833333333333333341666666667e-1 (5.74e-40%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '0.0000001 + 0.001j'
>>> \mathrm{d}z = dec.sinc(z); mz = mpm.sinc(z); iz = ipm.sinc(z)

```

3.7 Trigonometric functions, in multiples of π

3.7.1 Auxiliary function $\mathrm{sinpi}(x) = \sin(\pi x)$

`ctx.sinpi(`x`)`

where `ctx` is `math53`, `mathc53`, `ctxcpp`, `ctxflint`.

Returns the sine of $x \cdot \pi$. See also BoostMath [111], Ehrhardt [297] (4.2.57), Flint [748], Flint [738], Mpmath [558].

The function can also be expressed as

$$\sin(\pi z) = \frac{\pi}{\Gamma(z)\Gamma(1-z)}$$

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.SinPi(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.SinPi('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '1'
>>> \mathrm{d}x = dec.sinpi(x); mx = mpm.sinpi(x); ix = ipm.sinpi(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  1.6939937510582097494459230781640628620 90E-40
mpm:  0.0e+0
ipm:  1.6112552469844989999483063650938599815 82e-40 (14.25%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '1'
>>> fx = fpm.sinpi(x); gx = gmp.sinpi(x); ax = apm.sinpi(x)
>>> mpm.show([fx, gx, ax])
fpm:  -0.0000000000000000E+00

apm: 0.0e+0 (0.0%)             - 3.1415978213051234531e-3 (-1.58e-19%)j
```

3.7.2 Auxiliary function $\mathrm{cospi}(x) = \cos(\pi x)$

`ctx.cospi(`x`)`

where `ctx` is `math53`, `mathc53`, `ctxcpp`, `ctxflint`.

Returns $\cos(\pi x)$. See also BoostMath [98], Flint [748], Flint [738], Mpmath [541].

The function is calculated as

$$\cos(\pi z) = \frac{\pi}{\Gamma\left(\frac{1}{2}+z\right)\Gamma\left(\frac{1}{2}-z\right)}$$

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.CosPi(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.CosPi('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '0.5'
>>> \mathrm{d}x = dec.cospi(x); mx = mpm.cospi(x); ix = ipm.cospi(x)
>>> mpm.show([\mathrm{d}x, mx, ix])

```

3.7.3 Auxiliary function $\mathrm{tanpi}(x) = \tan(\pi x)$

`ctx.tanpi`(x)

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns $\tan(\pi x)$. See also BoostMath [98], Flint [748], Flint [738].

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.TanPi(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.TanPi('0.51')
ereal('5.351847902755998475 4E-1')
```

3.7.4 Auxiliary function $\mathrm{cotpi}(x) = \cot(\pi x)$

`ctx.cotpi(x)`

Returns $\cot(\pi x)$. See also BoostMath [98], Flint [748], Flint [738].

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.TanPi(0.5)
ereal('5.2359877559829887307E-1')
>>> ereal.TanPi('0.51')
ereal('5.351847902755998475 4E-1')
```

3.7.5 Auxiliary function $\mathrm{cscpi}(x) = \csc(\pi x)$

`ctx.cscpi(x)`

Returns $\mathrm{cscpi}(x)$. See also BoostMath [98], Flint [748], Flint [738].

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.TanPi(0.5)
ereal('5.2359877559829887307E-1')
>>> ereal.TanPi('0.51')
ereal('5.351847902755998475 4E-1')
```

3.7.6 Auxiliary function $\mathrm{secpi}(x) = \sec(\pi x)$

`ctx.secpi(x)`

Returns $\mathrm{secpi}(x)$. See also BoostMath [98], Flint [748], Flint [738].

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.TanPi(0.5)
ereal('5.2359877559829887307E-1')
>>> ereal.TanPi('0.51')
ereal('5.351847902755998475 4E-1')
```

3.7.7 Auxiliary function $\mathrm{sincpi}(x) = \mathrm{sinc}(\pi x)$

`ctx.sincpi(x)`

where `ctx` is `math53`, `mathc53`, `ctxcpp`, `ctxflint`.

Returns the cardinal sine of x. See also Wikipedia [1294], MathWorld [936], BoostMath [127], Flint [748], Flint [738], Mpmath [539].

`sincpi(x)` computes the normalized sinc function, defined as $\mathrm{sinc}_\pi(x) = \begin{cases} \sin(\pi x)/(\pi x), & \text{if } x \neq 0 \\ 1, & \text{if } x = 0. \end{cases}$

We also have

$$\mathrm{sinc}(\pi z) = \frac{1}{\Gamma(1+z)\,\Gamma(1-z)}$$

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.SincPi(0.5)
ereal('5.2359877559829887307E-1')
>>> ereal.SincPi('0.51')
ereal('5.3518479027559984754E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '1'
>>> \mathrm{d}x = dec.sincpi(x); mx = mpm.sincpi(x); ix = ipm.sincpi(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  5.3921495809539137379799049791268736155 91E-41
mpm:  0.0e+0
ipm:  5.1287847428067140430269195189123357055 33e-41 (14.25%)

>>> from xlcalcnet import mpm, fpm, gmp, apm

```

3.8 Hyperbolic functions

For a general introduction into hyperbolic functions, see Wikipedia [1240], NIST [486].

3.8.1 Hyperbolic sine, $\sinh(x)$

`ctx.sinh(x)`

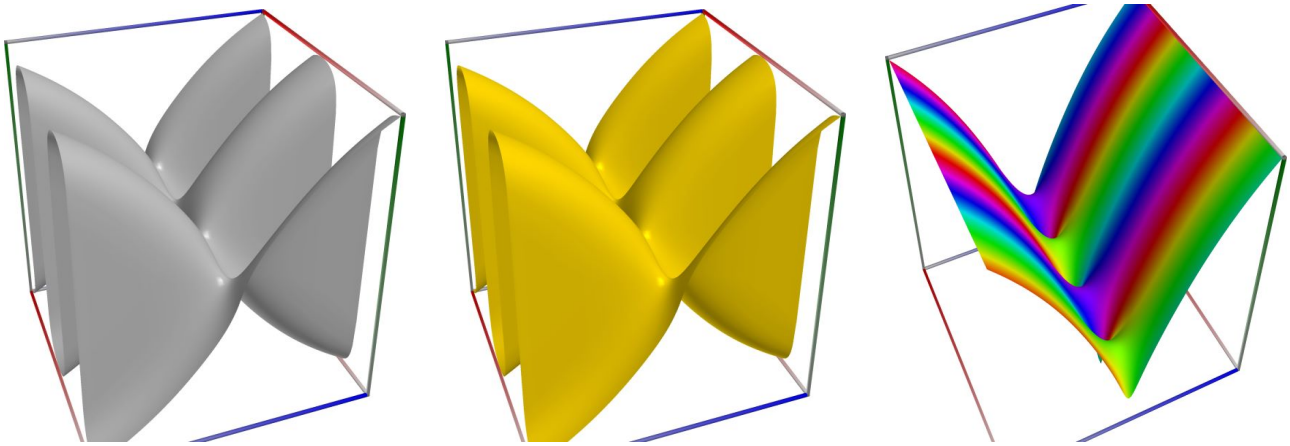
where `ctx` is `math53`, `mathc53`, `ctxcpp`, `ctxflint`.

Returns the hyperbolic sine of x, $\sinh(x)$. See also Wikipedia [1240], MathWorld [867], NIST [486], Ehrhardt [297] (4.2.56), Flint [742], Flint [732], Mpmath [567].

The hyperbolic sine can be expressed in terms of the exponential function as $\sinh(x) = \dfrac{e^x - e^{-x}}{2} = \dfrac{e^{2x-1}}{2e^x} = \dfrac{1 - e^{-2x}}{2e^x}$.

The complex hyperbolic sine can be expressed in terms of related functions:

$$\sinh(z) = \frac{e^z - e^{-z}}{2} = \frac{e^{2z-1}}{2e^z} = \frac{1 - e^{-2z}}{2e^z} = -i\sin(iz)$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Sinh(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Sinh('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '3.14159265358979'
>>> \mathrm{d}x = dec.sinh(x); mx = mpm.sinh(x); ix = ipm.sinh(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  1.1548739357257710837869687694559984769 91E+1
mpm:  1.1548739357257710837869687694559984769 91e+1
ipm:  1.1548739357257710837869687694559984769 91e+1 (3.181e-39%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '3.14159265358979'
>>> fx = fpm.sinh(x); gx = gmp.sinh(x); ax = apm.sinh(x)
```

(continues on next page)

(continued from previous page)

```
>>> mpm.show([fx, gx, ax])
fpm:  1.15487393572577E+01
gmp:  1.154873935725771083786968769455998476991E+01
apm:  1.154873935725771083786968769455998476991e+1 (3.181e-39%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm

(-3.59056458998577995201256 5 + 0.530921086248519805267040 1j)
```

3.8.2 Hyperbolic cosine, $\cosh(x)$

`ctx.cosh`(x)

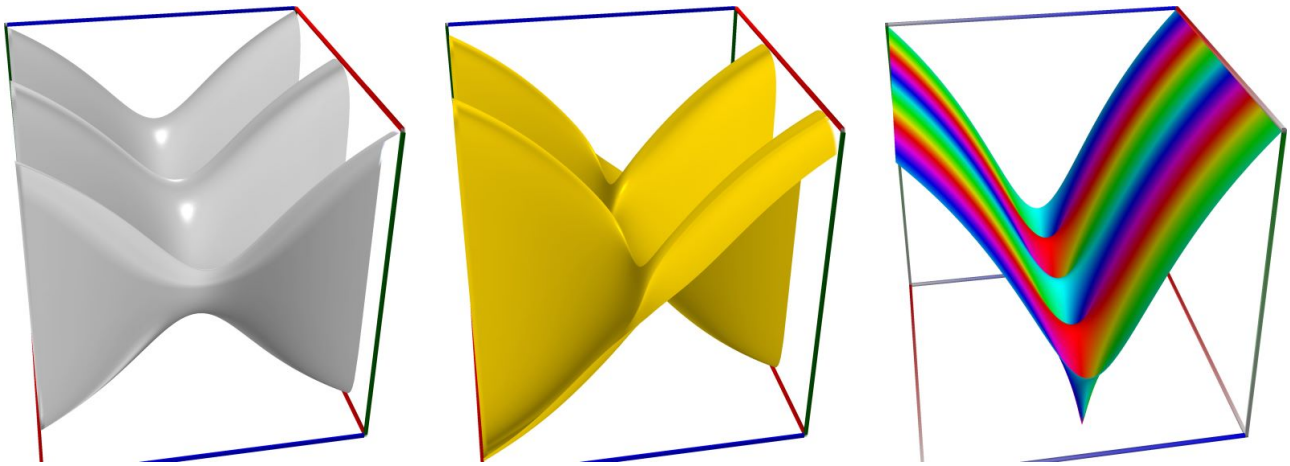
where `ctx` is `math53`, `mathc53`, `ctxcpp`, `ctxflint`.

Returns the hyperbolic cosine of x, $\cosh(x)$. See also Wikipedia [1240], MathWorld [864], NIST [486], Ehrhardt [297] (4.2.20), Flint [742], Flint [732], Mpmath [564].

The hyperbolic cosine can be expressed in terms of the exponential function as $\cosh(x) = \dfrac{e^x + e^{-x}}{2} = \dfrac{e^{2x+1}}{2e^x} = \dfrac{1 + e^{-2x}}{2e^x}$.

The complex hyperbolic cosine can be expressed in terms of related functions:

$$\cosh(z) = \frac{e^z + e^{-z}}{2} = \frac{e^{2z+1}}{2e^z} = \frac{1 + e^{-2z}}{2e^z} = \cos(iz)$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \leq x \leq 6$ (blue axis), $-6 \leq y \leq 6$ (red axis), $-10 \leq z \leq 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Cosh(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Cosh('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '1.57079632679489'
>>> \mathrm{d}x = dec.cosh(x); mx = mpm.cosh(x); ix = ipm.cosh(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  6.619231321691639751442098584651351473054E-15
mpm:  6.619231321691639751442098575708073666164e-15
ipm:  6.619231321691639751442098587187510685913e-15 (1.734e-25%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '1.57079632679489'
>>> fx = fpm.cosh(x); gx = gmp.cosh(x); ax = apm.cosh(x)
>>> mpm.show([fx, gx, ax])
fpm:  6.72257048770831E-15
gmp:  6.619231321691639751442098575708073666164E-15
apm:  6.619231321691639751442098584676383837843e-15 (1.768e-25%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '1.5E+2 - 3.14159265358979j'
>>> \mathrm{d}z = dec.cosh(z); mz = mpm.cosh(z); iz = ipm.cosh(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: -6.9685479033318984866E+64              - 2.2567382063567230055E+50j
mpm: -6.9685479033318984866e+64              - 2.2567375654278714043e+50j
ipm: -6.9685479033318984866e+64 (-6.4e-20%) - 2.2567387459458051327e+50 (-5.231e-5%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '1.5E+2 - 3.14159265358979j'
>>> fz = fpm.cosh(z); gz = gmp.cosh(z); az = apm.cosh(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: -6.96854790333190E+64                   - 2.25159995138029E+50j
gmp: -6.9685479033318984866E+64              - 2.2567375654278714043E+50j
apm: -6.9685479033318984866e+64 (-6.4e-20%) - 2.2567382294692091265e+50 (-5.406e-5%)j
```

Generalized to complex numbers, the hyperbolic cosine is equivalent to a cosine with the argument rotated in the imaginary direction, or $\cosh x = \cos ix$:

```
>>> from xlcalcnet import dec, mpr, ivr, ivc
>>> ivr.dps = 25; ivr.pretty = True
>>> cosh(2+3j)
(-3.724545504915322565473971 + 0.51182256998738460883446 38j)
>>> cos(3-2j)
(-3.724545504915322565473971 + 0.51182256998738460883446 38j)
```

3.8.3 Hyperbolic tangent, $\tanh(x)$

`ctx.tanh`(x)

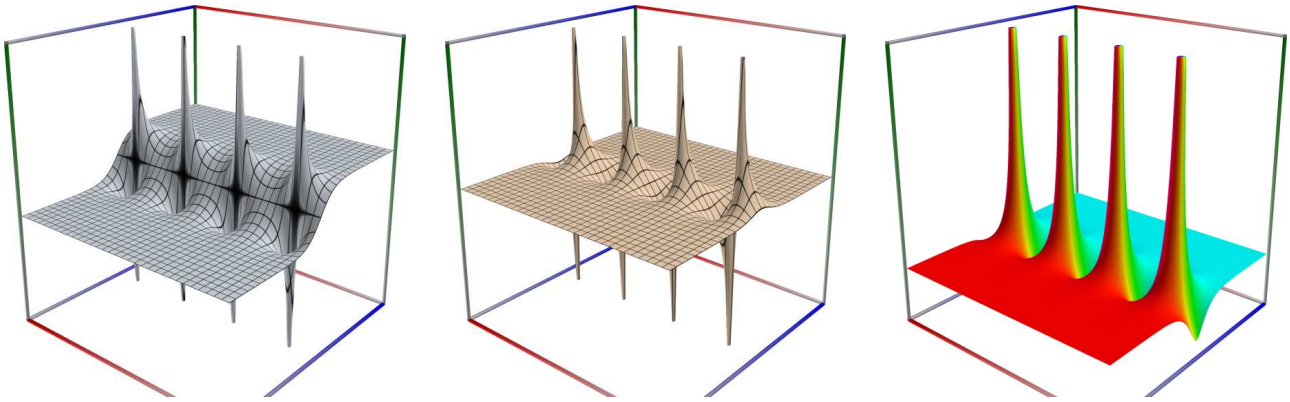
where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the hyperbolic tangent of x, $\tanh(x)$. See also Wikipedia [1240], MathWorld [868], NIST [486], Ehrhardt [297] (4.2.62), Flint [742], Flint [732], Mpmath [568].

The hyperbolic tangent can be expressed in terms of the exponential function as $\tanh(x) = \dfrac{\sinh(x)}{\cosh(x)} = \dfrac{e^x - e^{-x}}{e^x + e^{-x}} = \dfrac{e^{2x-1}}{e^{2x+1}}$.

The complex hyperbolic tangent can be expressed in terms of related functions:

$$\tanh(z) = \frac{\sinh(z)}{\cosh(z)} = \frac{e^z - e^{-z}}{e^z + e^{-z}} = \frac{e^{2z-1}}{e^{2z+1}} = -i\tan(iz)$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Tanh(0.5)
ereal('5.2359877559829887307E-1')
>>> ereal.Tanh('0.51')
ereal('5.3518479027559984754E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '1.57079632679489'
>>> \mathrm{d}x = dec.tanh(x); mx = mpm.tanh(x); ix = ipm.tanh(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  9.171523356672732950300364697768401207429E-1

apm: 1.0000003333333111111e+3 (1.301e-19%) - 6.619229123532757354 8e-9 (-1.32e-5%)j
```

3.8.4 Hyperbolic cotangent, $\coth(x)$

ctx.coth(x)

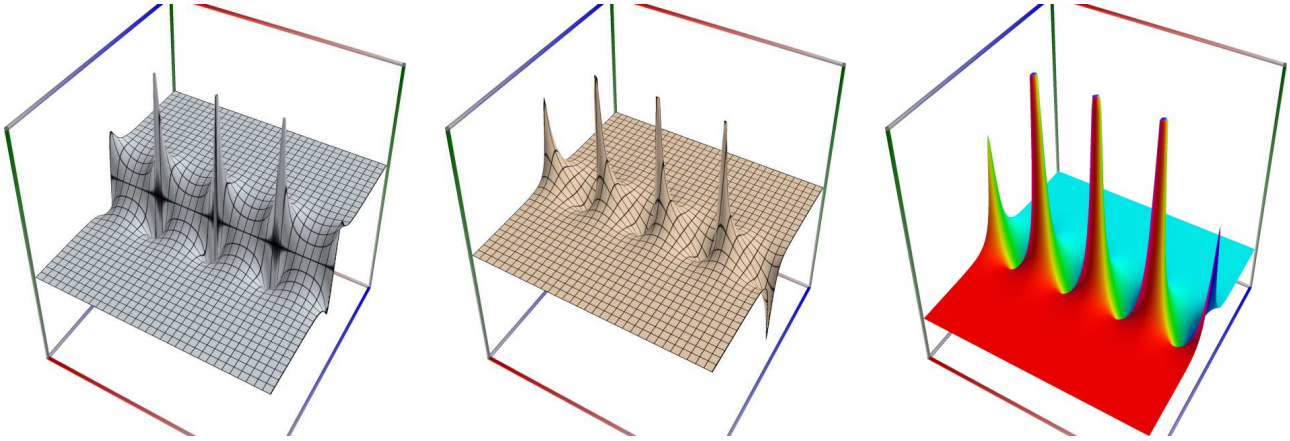
where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the hyperbolic cotangent of x, $\coth(x)$. See also Wikipedia [1240], MathWorld [865], NIST [486], Ehrhardt [297] (4.2.22), Flint [742], Flint [732], Mpmath [565].

The hyperbolic cotangent can be expressed in terms of related functions as $\coth(x) = \dfrac{\cosh(x)}{\sinh(x)} = \dfrac{e^x + e^{-x}}{e^x - e^{-x}} = \dfrac{e^{2x+1}}{e^{2x-1}}$.

The complex hyperbolic cotangent can be expressed in terms of related functions:

$$\coth(z) = \frac{\cosh(z)}{\sinh(z)} = \frac{e^z + e^{-z}}{e^z - e^{-z}} = \frac{e^{2z+1}}{e^{2z-1}} = i \cdot \cot(iz)$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Coth(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Coth('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm

apm: 9.9999966666679999995e-4 (1.654e-19%) + 6.619224710715842 2627e-15 (1.32e-5%)j
```

3.8.5 Hyperbolic cosecant, $\operatorname{csch}(x)$

`ctx.csch(`x`)`

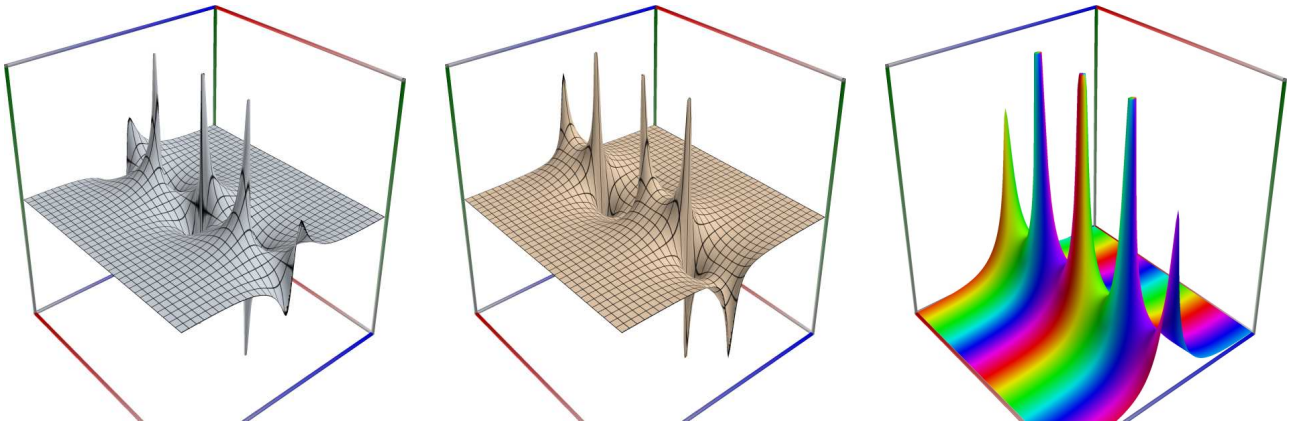
where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the hyperbolic cosecant of x, $\operatorname{csch}(x)$. See also Wikipedia [1240], MathWorld [863], NIST [486], Ehrhardt [297] (4.2.24), Flint [742], Flint [732], Mpmath [563].

The hyperbolic cosecant can be expressed in terms of the exponential function as $\operatorname{csch}(x) = \dfrac{1}{\sinh(x)} = \dfrac{2}{e^x - e^{-x}} = \dfrac{2e^x}{1 - e^{-2x}}$.

The complex hyperbolic cosecant can be expressed in terms of related functions:

$$\operatorname{csch}(z) = \frac{1}{\sinh(z)} = \frac{2}{e^z - e^{-z}} = \frac{2e^z}{1 - e^{-2z}} = i \cdot \operatorname{csc}(iz)$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \leq x \leq 6$ (blue axis), $-6 \leq y \leq 6$ (red axis), $-10 \leq z \leq 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Csch(0.5)
ereal('5.2359877559829887307E-1')
>>> ereal.Csch('0.51')
ereal('5.3518479027559984754E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '3.14159265358979'
>>> \mathrm{d}x = dec.csch(x); mx = mpm.csch(x); ix = ipm.csch(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  8.658953753004722329472715990465035467380E-2
mpm:  8.658953753004722329472715990465035467381e-2
ipm:  8.658953753004722329472715990465035467380e-2 (7.457e-39%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '3.14159265358979'

apm: 9.498724012183199560 1e-80 (1.326e-5%) + 1.435019194632882084 0e-65 (5.605e-20%)j
```

3.8.6 Hyperbolic secant, $\mathrm{sech}(x)$

`ctx.sech`(x)

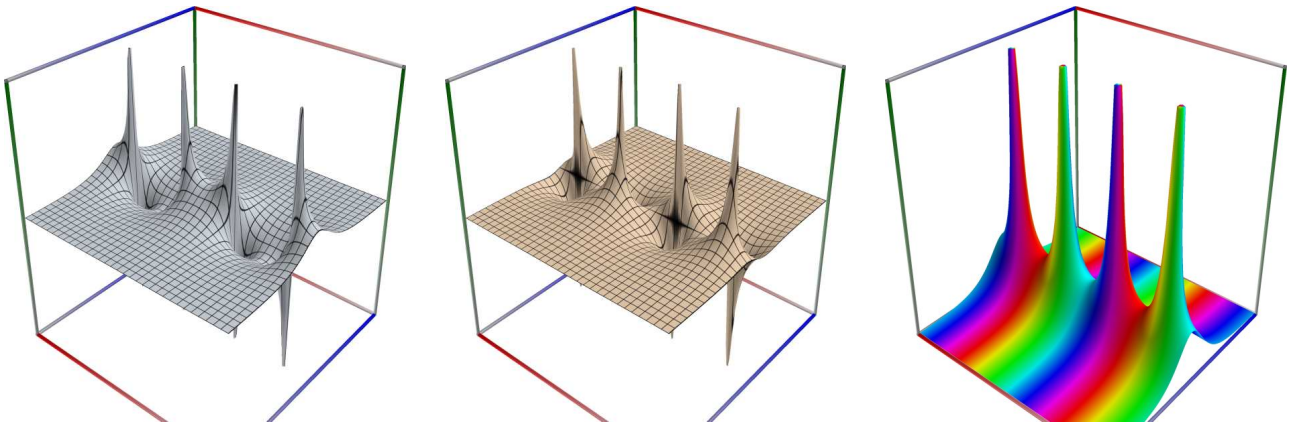
where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the hyperbolic secant of x, $\mathrm{sech}(x)$. See also Wikipedia [1240], MathWorld [866], NIST [486], Ehrhardt [297] (4.2.54), Mpmath [566].

The hyperbolic secant can be expressed in terms of the exponential function as $\mathrm{sech}(x) = \dfrac{1}{\cosh(x)} = \dfrac{2}{e^x + e^{-x}} = \dfrac{2e^x}{e^{2x}+1}$.

The complex hyperbolic secant can be expressed in terms of related functions:

$$\mathrm{sech}(z) = \frac{1}{\cosh(z)} = \frac{2}{e^z + e^{-z}} = \frac{2e^z}{e^{2z}+1} = \sec(iz)$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Sech(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Sech('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '1.57079632679489'
>>> \mathrm{d}x = dec.sech(x); mx = mpm.sech(x); ix = ipm.sech(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  3.9853681533838909988824430189041636662 17E-1
mpm:  3.9853681533838909988824430189041636662 17e-1
ipm:  3.9853681533838909988824430189041636662 17e-1 (4.321e-39%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '1.57079632679489'
>>> fx = fpm.sech(x); gx = gmp.sech(x); ax = apm.sech(x)
>>> mpm.show([fx, gx, ax])
fpm:  3.98536815338389E-01
gmp:  3.9853681533838909988824430189041636662 17E-01
apm:  3.9853681533838909988824430189041636662 17e-1 (2.16e-39%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '1.5E+2 - 3.14159265358979j'
>>> \mathrm{d}z = dec.sech(z); mz = mpm.sech(z); iz = ipm.sech(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: -1.4350191946328820840E-65               + 4.6472560543565481719E-80j

3.9 Inverse trigonometric functions, in radians

For a general introduction to inverse trigonometric functions, see Wikipedia [1262], NIST [488].

3.9.1 Inverse sine, $\mathrm{asin}(x)$

`ctx.asin(x)`

where `ctx` is `math53`, `mathc53`, `ctxcpp`, `ctxflint`.

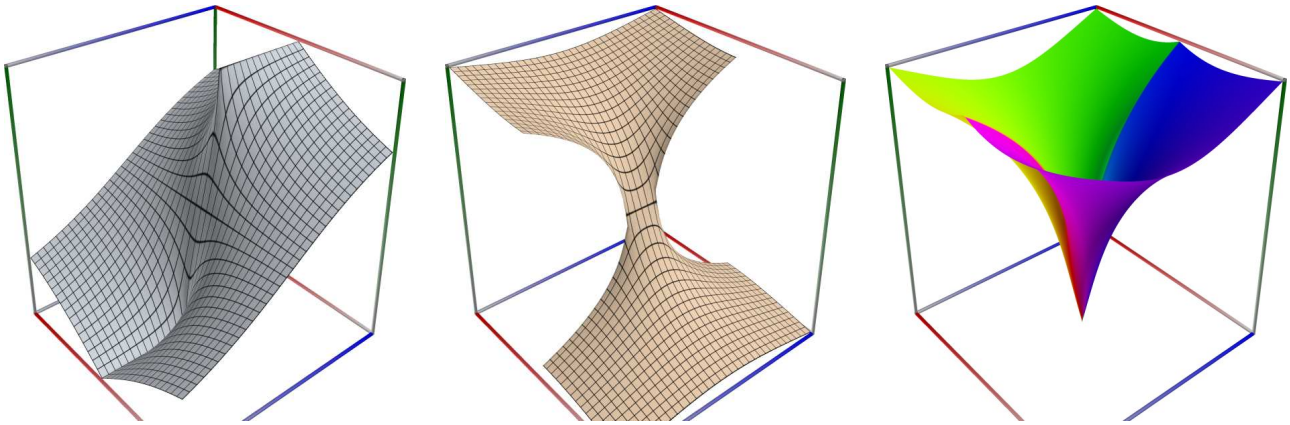
Returns the inverse sine of x, $\mathrm{asin}(x)$. See also Wikipedia [1262], MathWorld [873], NIST [488], Ehrhardt [297] (4.2.13), Mpmath [579].

The inverse sine can be expressed in terms of the inverse tangent as $\mathrm{asin}(x) = \mathrm{atan}\left(\frac{x}{\sqrt{1-x^2}}\right)$. The domain is the open interval $(-1, 1)$. We have $\sin(\mathrm{asin}(x)) = x$ for all x, but $\mathrm{asin}(\sin(x)) = x$ only for $-\pi/2 < x < \pi/2$.

The inverse sine can be expressed in terms of related functions (with the principal-branch log and square root):

$$\mathrm{asin}(z) = -i \log\left(iz + \sqrt{1-z^2}\right)$$

The inverse sine has two branch points: $x = \pm 1$.The branch cuts are placed along the line segments $(-\infty, -1)$ and $(+1, +\infty)$. Since $-1 \le \sin(x) \le 1$ for real x, the inverse sine is real-valued only for $-1 \le x \le 1$. On this interval, it is defined to be a monotonically increasing function assuming values between $-\pi/2$ and $\pi/2$.



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Asin(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Asin('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '1'
>>> \mathrm{d}x = dec.asin(x); mx = mpm.asin(x); ix = ipm.asin(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  1.5707963267948966192313216916397514420 99E+0
mpm:  1.5707963267948966192313216916397514420 99e+0
```

(continues on next page)

(continued from previous page)

```
ipm:  1.57079632679489661923132169163975144209 9e+0 (7.308e-40%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '1'
>>> fx = fpm.asin(x); gx = gmp.asin(x); ax = apm.asin(x)
>>> mpm.show([fx, gx, ax])
fpm:  1.57079632679490E+00

apm:  1.57079632679489661923132169163975144209 9e+0 (1.462e-39%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '1 + 1.5E-2j'
>>> \mathrm{d}z = dec.asin(z); mz = mpm.asin(z); iz = ipm.asin(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 1.44847544713554775 67E+0              + 1.22627061264029 98997E-1j
mpm: 1.44847544713554775 67e+0              + 1.22627061264029 98997e-1j
ipm: 1.44847544713554775 67e+0 (1.754e-19%) + 1.22627061264029 98997e-1 (1.295e-18%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '1 + 1.5E-2j'
>>> fz = fpm.asin(z); gz = gmp.asin(z); az = apm.asin(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 1.44847544713555E+00                  + 1.22627061264030E-01j
gmp: 1.44847544713554775 67E+00            + 1.22627061264029 98997E-01j
apm: 1.44847544713554775 67e+0 (5.848e-20%) + 1.22627061264029 98997e-1 (1.727e-19%)j
```

$\mathrm{asin}(z)$ is defined so as to be a proper inverse function of $\sin(\theta)$ for $-\pi/2 < \theta < \pi/2$. We have $\sin(\sin^{-1}(x)) = x$ for all x, but $\sin^{-1}(\sin(x)) = x$ only for $-\pi/2 < \Re[x] < \pi/2$:

```
>>> from xlcalcnet import dec, mpr, ivr, ivc
>>> ivr.dps = 25; ivr.pretty = True
>>> for x in [1, 10, -1, 1+3j, -2+3j]:
...     print("%s %s" % (chop(sin(asin(x))), asin(sin(x))))
...
1.0 1.0
10.0 -0.57522203923062028461206 98
-1.0 -1.0
(1.0 + 3.0j) (1.0 + 3.0j)
(-2.0 + 3.0j) (-1.14159265358979323846264 3 - 3.0j)
```

3.9.2 Inverse cosine, $\mathrm{acos}(x)$

ctx.acos(x)

where `ctx` is `math53`, `mathc53`, `ctxcpp`, `ctxflint`.

Returns the inverse cosine of x, $\mathrm{acos}(x)$. See also Wikipedia [1262], MathWorld [870], NIST [488], Ehrhardt [297] (4.2.3), Flint [745], Flint [735], Mpmath [570].

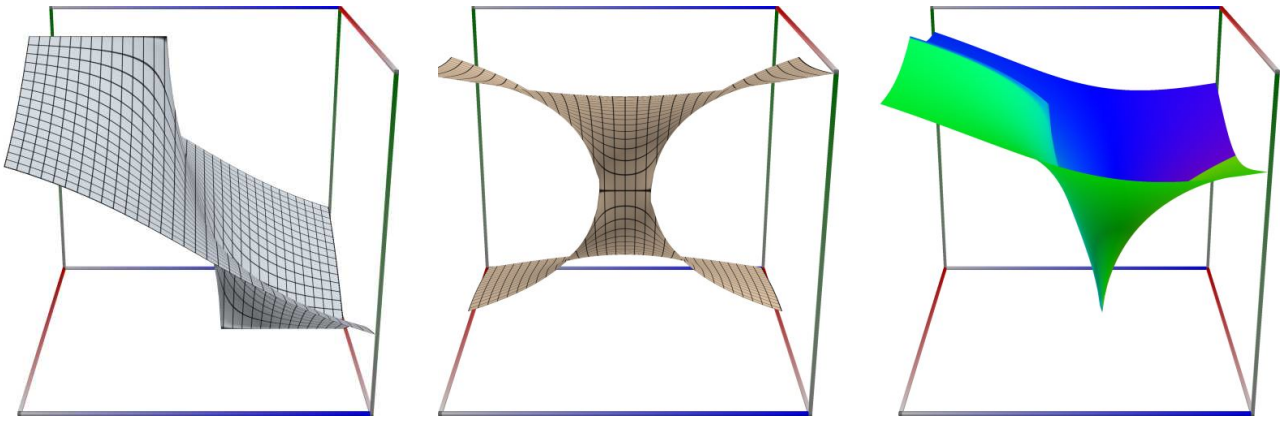
The inverse cosine can be expressed in terms of the inverse tangent as $\mathrm{acos}(x) = \mathrm{atan}\left(\dfrac{\sqrt{1-x^2}}{x}\right)$. The domain is the open interval $(-1, 1)$. We have $\cos(\mathrm{acos}(x)) = x$ for all x, but $\mathrm{acos}(\cos(x)) = x$ only for $0 \le x < \pi$.

The inverse cosine can be expressed in terms of related functions (with the principal-branch log and square root):

$$\mathrm{acos}(z) = \frac{\pi}{2} + i \log\left(iz + \sqrt{1-z^2}\right)$$

The inverse cosine has two branch points: $x = \pm 1$.The branch cuts are placed along the line segments $(-\infty, -1)$ and $(+1, +\infty)$.

Since $-1 \leq \cos(x) \leq 1$ for real x, the inverse cosine is real-valued only for $-1 \leq x \leq 1$, where it is a monotonically decreasing function assuming values between $+\pi$ and 0.



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \leq x \leq 6$ (blue axis), $-6 \leq y \leq 6$ (red axis), $-10 \leq z \leq 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Acos(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Acos('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '0.5'
>>> \mathrm{d}x = dec.acos(x); mx = mpm.acos(x); ix = ipm.acos(x)
>>> mpm.show([\mathrm{d}x, mx, ix])

(10.0 + 0.0j) 2.5663706143591729538505735
-1.0 1.0
(2.0 + 3.0j) (2.0 + 3.0j)
(10.0 + 3.0j) (2.5663706143591729538505735 - 3.0j)
```

3.9.3 Inverse tangent, $\operatorname{atan}(x)$

`ctx.atan(x)`

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

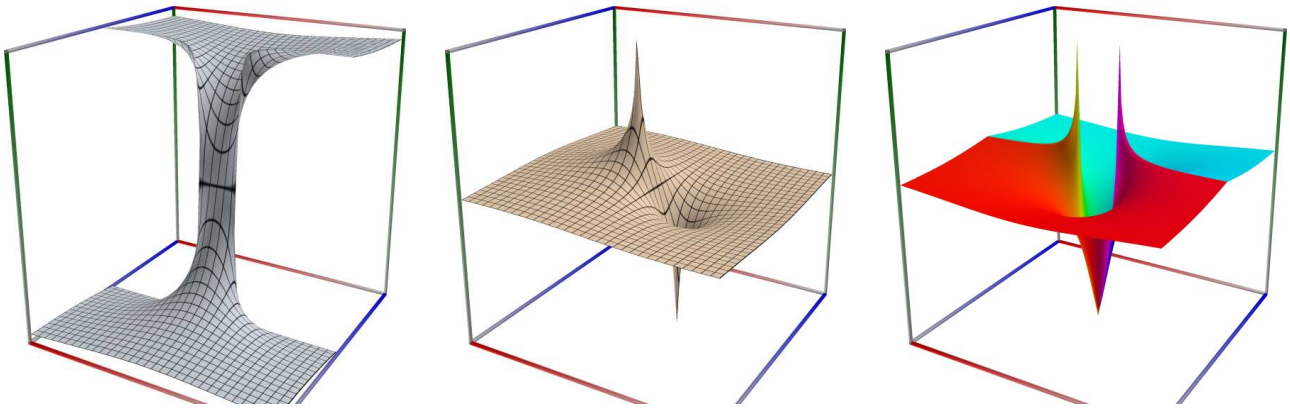
Returns the inverse tangent of x, $\operatorname{atan}(x)$. See also Wikipedia [1262], MathWorld [874], NIST [488], Ehrhardt [297] (4.2.15), Flint [745], Flint [735], Mpmath [580].

The inverse tangent can be defined as $\operatorname{atan}(x) = \int_0^x \frac{1}{t^2+1} dt$. This is a real-valued function for all real x, with range $(-\pi/2, \pi/2)$. We have $\tan(\operatorname{atan}(x)) = x$ for all x, but $\operatorname{atan}(\tan(x)) = x$ only for $-\pi/2 < x < \pi/2$.

The inverse tangent can be expressed in terms of related functions (with the principal-branch log and square root):

$$\operatorname{atan}(z) = \frac{i}{2}\left(\log(1-iz) - \log(1+iz)\right)$$

The inverse tangent has two branch points: $x = \pm i$.The branch cuts are placed along the line segments $(-i\infty, -i)$ and $(+i, +i\infty)$.



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Atan(0.5)
ereal('5.23598775598298873077E-1')
>>> ereal.Atan('0.51')
ereal('5.35184790275599847547E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '0.5'
>>> \mathrm{d}x = dec.atan(x); mx = mpm.atan(x); ix = ipm.atan(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  4.6364760900080611621425623146121440202 85E-1

```

3.9.4 Inverse tangent, 2 arguments, $\operatorname{atan2}(y, x)$

`ctx.atan2`(y, x)

where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the inverse tangent of x and y. See also Wikipedia [1275], MathWorld [874], Flint [745], Flint [735], Mpmath [617].

Computes the two-argument arctangent, $\mathrm{atan2}(y, x)$, giving the signed angle between the positive x-axis and the point (x, y) in the 2D plane. This function is defined for real x and y only.

The two-argument arctangent essentially computes $\mathrm{atan}(y/x)$, but accounts for the signs of both x and y to give the angle for the correct quadrant. The following examples illustrate the difference:

An example in Python

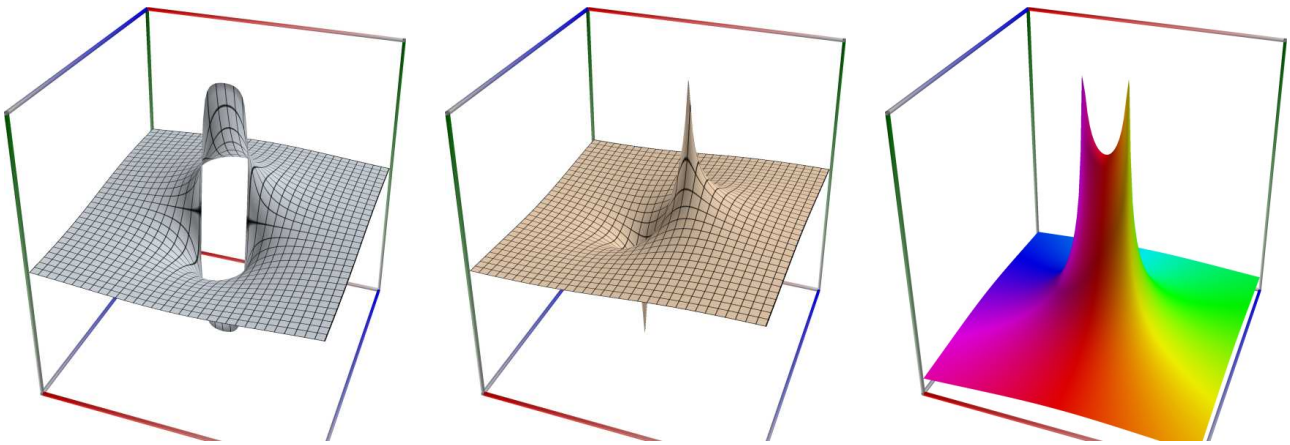
```
>>> from xlcalcnet import ereal
>>> ereal.Atan2(1,1), ereal.Atan(1/1.)
(0.785398163397448, 0.785398163397448)
>>> ereal.Atan2(1,-1), ereal.Atan(1/-1.)
(2.35619449019234, -0.785398163397448)
>>> ereal.Atan2(-1,1), ereal.Atan(-1/1.)
(-0.785398163397448, -0.785398163397448)
>>> ereal.Atan2(-1,-1), ereal.Atan(-1/-1.)
(-2.35619449019234, 0.785398163397448)
```

The angle convention is the same as that used for the complex argument.

3.9.5 Inverse cotangent, $\mathrm{acot}(x)$

`ctx.acot(`x`)`

Returns the inverse cotangent of x, $\mathrm{acot}(x)$. See also Wikipedia [1262], MathWorld [871], NIST [488], Ehrhardt [297] (4.2.5).



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

The inverse cotangent can be expressed in terms of the inverse tangent as $\mathrm{acot}(x) = \mathrm{atan}\left(\frac{1}{x}\right)$. This is a real-valued function for all real x, with range $(0, \pi)$.

The inverse cotangent can be expressed in terms of related functions (with the principal-branch log and square root):

$$\mathrm{acot}(z) = \frac{i}{2}\left[\log\left(1 - \frac{i}{z}\right) - \log\left(1 + \frac{i}{z}\right)\right] = \mathrm{atan}\left(\frac{1}{z}\right)$$

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Acot(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Acot('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '2.0'
>>> \mathrm{d}x = dec.asec(x); mx = mpm.asec(x); ix = ipm.asec(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  1.047197551196597746154214461093167628066E+0
mpm:  1.047197551196597746154214461093167628066e+0
ipm:  1.047197551196597746154214461093167628066e+0 (1.096e-39%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '2.0'
>>> fx = fpm.asec(x); gx = gmp.asec(x); ax = apm.asec(x)
>>> mpm.show([fx, gx, ax])
fpm:  1.04719755119660E+00
gmp:  1.047197551196597746154214461093167628066E+00
apm:  1.047197551196597746154214461093167628066e+0 (1.096e-39%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '2.0 + 1.5E-2j'
>>> \mathrm{d}z = dec.asec(z); mz = mpm.asec(z); iz = ipm.asec(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 1.0472354363409255922E+0              + 4.3297752322606827325E-3j
mpm: 1.0472354363409255922e+0              + 4.3297752322606827325e-3j
ipm: 1.0472354363409255922e+0 (2.426e-19%) + 4.3297752322606827323e-3 (3.508e-17%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '2.0 + 1.5E-2j'
>>> fz = fpm.asec(z); gz = gmp.asec(z); az = apm.asec(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 1.04723543634093E+00                  + 4.32977523226068E-03j
gmp: 1.0472354363409255922E+00             + 4.329775232260682732 5E-03j
apm: 1.0472354363409255922e+0 (8.088e-20%) + 4.3297752322606827324e-3 (1.146e-18%)j
```

3.9.6 Inverse cosecant, $\operatorname{acsc}(x)$

ctx.acsc(x)

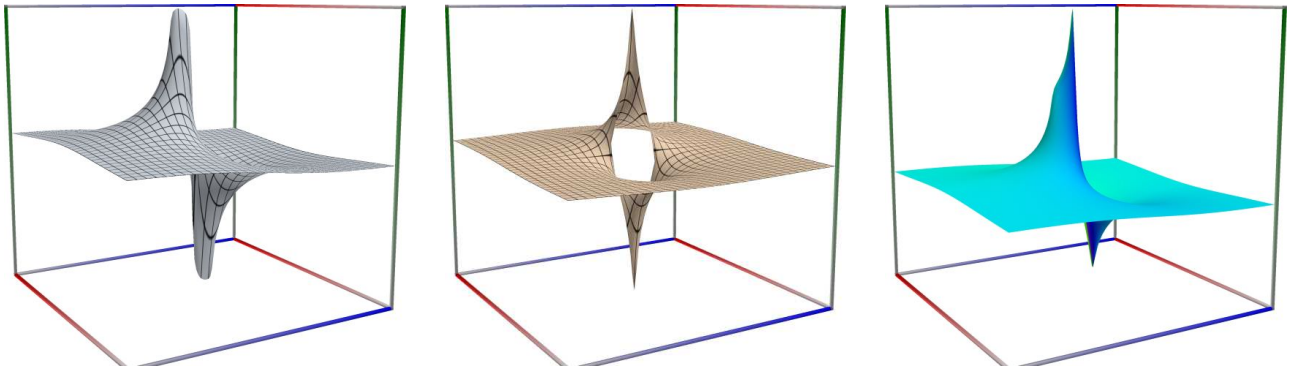
where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the inverse cosecant of x, $\operatorname{acsc}(x)$. See also Wikipedia [1262], MathWorld [869], NIST [488], Ehrhardt [297] (4.2.9), Mpmath [569].

The inverse cosecant can be expressed in terms of the inverse sine as $\operatorname{acsc}(x) = \operatorname{asin}\left(\frac{1}{x}\right)$. The domain is $\mathbb{R} \setminus (-1, 1)$, i.e. $|x| > 0$.

The inverse cosecant can be expressed in terms of related functions (with the principal-branch log and square root):

$$\operatorname{acsc}(z) = -i \log\left(\sqrt{1 - \frac{1}{z^2}} + \frac{i}{z}\right) = \operatorname{asin}\left(\frac{1}{z}\right)$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \leq x \leq 6$ (blue axis), $-6 \leq y \leq 6$ (red axis), $-10 \leq z \leq 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Acsc(0.5)
ereal('5.2359877559829887307E-1')
>>> ereal.Acsc('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '2.0'
>>> \mathrm{d}x = dec.acsc(x); mx = mpm.acsc(x); ix = ipm.acsc(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  5.2359877559829887307710723054658381403 29E-1
mpm:  5.2359877559829887307710723054658381403 29e-1
ipm:  5.2359877559829887307710723054658381403 29e-1 (2.192e-39%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '2.0'
>>> fx = fpm.acsc(x); gx = gmp.acsc(x); ax = apm.acsc(x)
>>> mpm.show([fx, gx, ax])
fpm:  5.2359877559829 9E-01
gmp:  5.2359877559829887307710723054658381403 29E-01
apm:  5.2359877559829887307710723054658381403 29e-1 (1.096e-39%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '2.0 + 1.5E-2j'
>>> \mathrm{d}z = dec.acsc(z); mz = mpm.acsc(z); iz = ipm.acsc(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 5.2356089045397102702E-1              - 4.3297752322606827325E-3j
mpm: 5.2356089045397102702e-1              - 4.3297752322606827325e-3j
ipm: 5.2356089045397102702e-1 (4.045e-19%) - 4.3297752322606827323e-3 (-3.508e-17%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '2.0 + 1.5E-2j'
>>> fz = fpm.acsc(z); gz = gmp.acsc(z); az = apm.acsc(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 5.23560890453971E-01                  - 4.32977523226068E-03j
gmp: 5.2356089045397102702E-01             - 4.3297752322606827325E-03j
apm: 5.2356089045397102702e-1 (8.089e-20%) - 4.3297752322606827324e-3 (-1.146e-18%)j
```

3.9.7 Inverse secant, $\operatorname{asec}(x)$

`ctx.asec(`x`)`

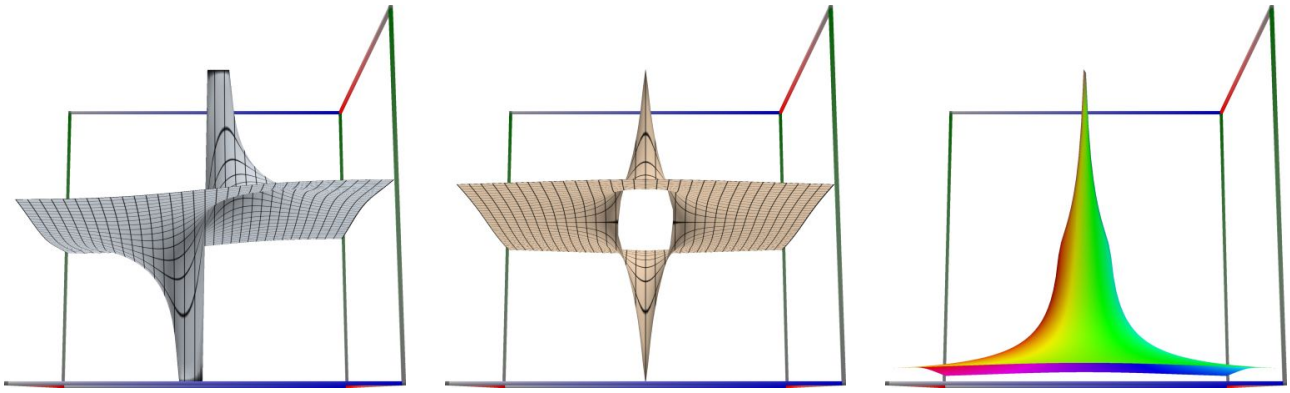
where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the inverse secant of x, $\operatorname{asec}(x)$. See also Wikipedia [1262], MathWorld [872], NIST [488], Ehrhardt [297] (4.2.11), Mpmath [578].

The inverse secant can be expressed in terms of the inverse cosine as $\operatorname{asec}(x) = \operatorname{acos}\left(\frac{1}{x}\right)$. The domain is $\mathbb{R} \setminus (-1, 1)$, i.e. $|x| > 0$.

The inverse secant can be expressed in terms of related functions (with the principal-branch log and square root):

$$\operatorname{asec}(z) = -i \log\left(\sqrt{\frac{1}{z^2} - 1} + \frac{1}{z}\right) = \operatorname{acos}\left(\frac{1}{z}\right)$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Asec(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Asec('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '2.0'
>>> \mathrm{d}x = dec.asec(x); mx = mpm.asec(x); ix = ipm.asec(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  1.0471975511965977461542144610931676280 66E+0
mpm:  1.0471975511965977461542144610931676280 66e+0
ipm:  1.0471975511965977461542144610931676280 66e+0 (1.096e-39%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '2.0'
>>> fx = fpm.asec(x); gx = gmp.asec(x); ax = apm.asec(x)
>>> mpm.show([fx, gx, ax])
fpm:  1.04719755119660E+00
gmp:  1.0471975511965977461542144610931676280 66E+00
apm:  1.0471975511965977461542144610931676280 66e+0 (1.096e-39%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '2.0 + 1.5E-2j'
>>> \mathrm{d}z = dec.asec(z); mz = mpm.asec(z); iz = ipm.asec(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 1.0472354363409255922E+0              + 4.3297752322606827325E-3j
mpm: 1.0472354363409255922e+0              + 4.3297752322606827325e-3j
ipm: 1.0472354363409255922e+0 (2.426e-19%) + 4.3297752322606827323e-3 (3.508e-17%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '2.0 + 1.5E-2j'
>>> fz = fpm.asec(z); gz = gmp.asec(z); az = apm.asec(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 1.04723543634093E+00                  + 4.32977523226068E-03j
gmp: 1.0472354363409255922E+00             + 4.3297752322606827325E-03j
apm: 1.0472354363409255922e+0 (8.088e-20%) + 4.3297752322606827324e-3 (1.146e-18%)j
```

3.10 Inverse hyperbolic functions

For a general introduction to inverse hyperbolic functions, see Wikipedia [1263], NIST [487].

3.10.1 Inverse hyperbolic sine, $\operatorname{asinh}(x)$

`ctx.asinh(`x`)`

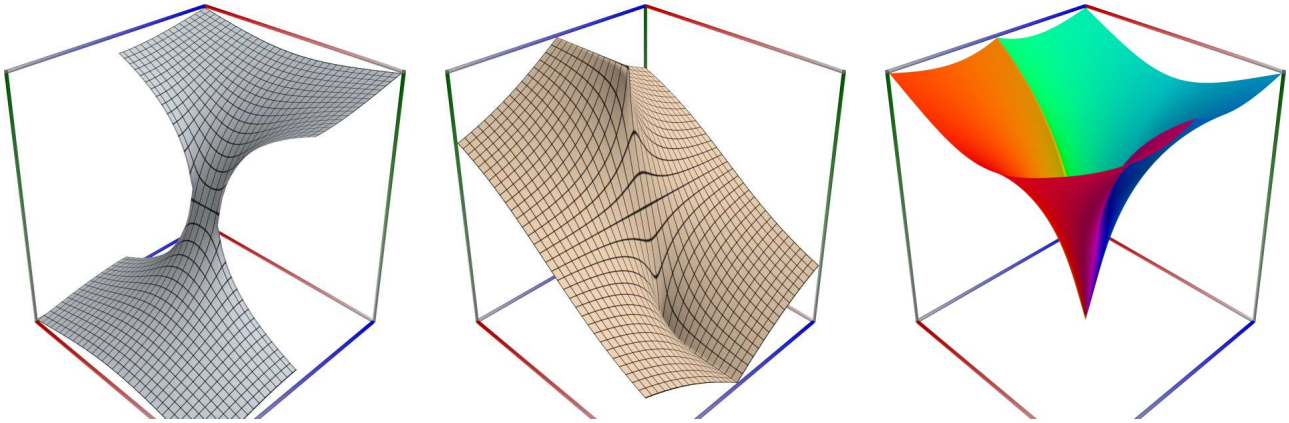
where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the inverse hyperbolic sine of x, $\operatorname{asinh}(x)$. See also Wikipedia [1263], MathWorld [891], NIST [487], Ehrhardt [297] (4.2.14), Flint [744], Flint [734], Mpmath [576].

The inverse hyperbolic sine can be defined as $\operatorname{asinh}(x) = \log\left(x + \sqrt{1+x^2}\right)$. The domain is the whole real line.

The inverse hyperbolic sine can be expressed in terms of related functions (with the principal-branch log and square root):

$$\operatorname{asinh}(z) = \log\left(z + \sqrt{1+z^2}\right) = \frac{1}{i}\operatorname{asin}(iz)$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Asinh(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Asinh('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '1'
>>> \mathrm{d}x = dec.asinh(x); mx = mpm.asinh(x); ix = ipm.asinh(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  8.8137358701954302523260932497979230902 82E-1
mpm:  8.8137358701954302523260932497979230902 82e-1
ipm:  8.8137358701954302523260932497979230902 82e-1 (3.907e-39%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '1'
>>> fx = fpm.asinh(x); gx = gmp.asinh(x); ax = apm.asinh(x)
>>> mpm.show([fx, gx, ax])
```

(continues on next page)

(continued from previous page)

```
fpm:  8.81373587019543E-01
gmp:  8.8137358701954302523260932497979230902 82E-01
apm:  8.8137358701954302523260932497979230902 82e-1 (6.512e-40%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '1 + 1.5E+2j'
>>> \mathrm{d}z = dec.asinh(z); mz = mpm.asinh(z); iz = ipm.asinh(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 5.703793586569763928 6E+0              + 1.564129610751110731 2E+0j
mpm: 5.703793586569763928 6e+0              + 1.564129610751110731 2e+0j
ipm: 5.703793586569763912 0e+0 (5.704e-16%) + 1.564129610751110731 3e+0 (3.016e-17%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '1 + 1.5E+2j'
>>> fz = fpm.asinh(z); gz = gmp.asinh(z); az = apm.asinh(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 5.70379358656976E+00                  + 1.56412961075111E+00j
gmp: 5.703793586569763928 6E+00            + 1.564129610751110731 2E+00j
apm: 5.703793586569763928 3e+0 (1.936e-17%) + 1.564129610751110731 2e+0 (1.083e-18%)j
```

3.10.2 Inverse hyperbolic cosine, $\operatorname{acosh}(x)$

`ctx.acosh`(x)

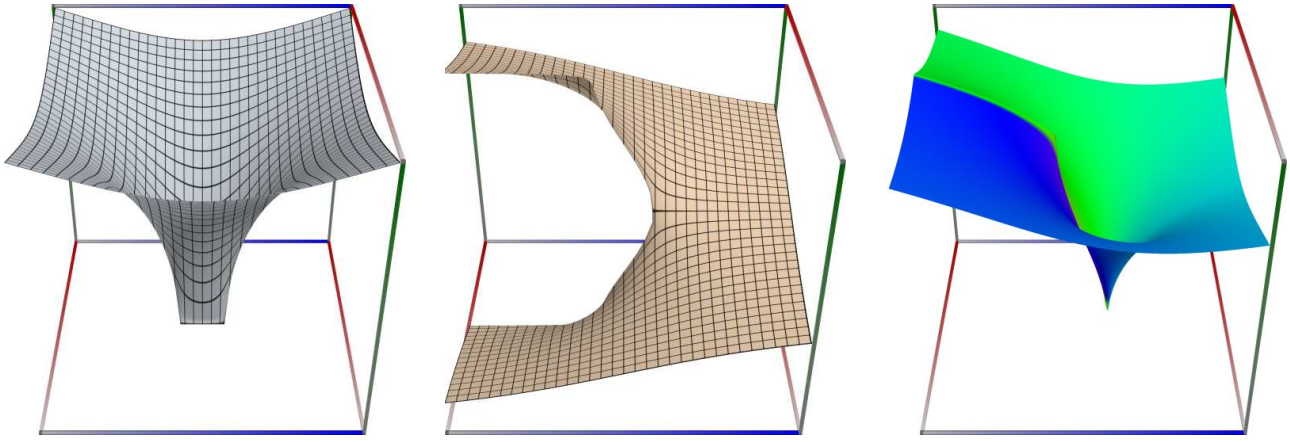
where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the inverse hyperbolic cosine of x, $\operatorname{acosh}(x)$. See also Wikipedia [1263], MathWorld [888], NIST [487], Ehrhardt [297] (4.2.4), Flint [744], Flint [734], Mpmath [573].

The inverse hyperbolic cosine can be defined as $\operatorname{acosh}(x) = \log\left(x + \sqrt{x^2 - 1}\right)$. The domain is the closed interval $[1, +\infty)$.

The inverse hyperbolic cosine can be expressed in terms of related functions (with the principal-branch log and square root):

$$\operatorname{acosh}(z) = \log\left(z + \sqrt{z+1}\sqrt{z-1}\right) = \frac{\sqrt{z-1}}{\sqrt{1-z}}\operatorname{acos}(z)$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Acosh(0.5)
ereal('5.2359877559829887307E-1')
>>> ereal.Acosh('0.51')
ereal('5.3518479027559984754E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '2'
>>> \mathrm{d}x = dec.acosh(x); mx = mpm.acosh(x); ix = ipm.acosh(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  1.3169578969248167086250463473079684440 27E+0
mpm:  1.3169578969248167086250463473079684440 27e+0
ipm:  1.3169578969248167086250463473079684440 27e+0 (8.717e-40%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '2'
>>> fx = fpm.acosh(x); gx = gmp.acosh(x); ax = apm.acosh(x)
>>> mpm.show([fx, gx, ax])
fpm:  1.31695789692482E+00
gmp:  1.3169578969248167086250463473079684440 27E+00
apm:  1.3169578969248167086250463473079684440 27e+0 (8.717e-40%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '2 + 1.5E+2j'
>>> \mathrm{d}z = dec.acosh(z); mz = mpm.acosh(z); iz = ipm.acosh(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 5.7038824606468806598E+0              + 1.5574640796818581268E+0j
mpm: 5.7038824606468806598e+0              + 1.5574640796818581268e+0j
ipm: 5.7038824606468806598e+0 (1.188e-19%) + 1.5574640796818581268e+0 (5.439e-20%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '2 + 1.5E+2j'
>>> fz = fpm.acosh(z); gz = gmp.acosh(z); az = apm.acosh(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 5.70388246064688E+00                 + 1.55746407968186E+00j

```

3.10.3 Inverse hyperbolic tangent, $\operatorname{atanh}(x)$

`ctx.atanh`(x)

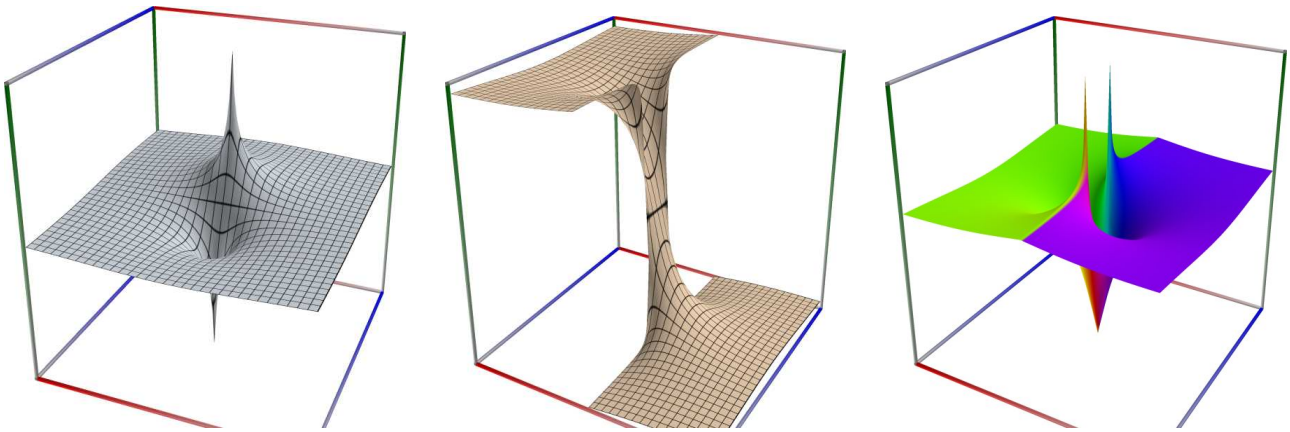
where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the inverse hyperbolic tangent of x, $\operatorname{atanh}(x)$. See also Wikipedia [1263], MathWorld [892], NIST [487], Ehrhardt [297] (4.2.16), Flint [744], Flint [734], Mpmath [577].

The inverse hyperbolic tangent can be defined as $\operatorname{atanh}(x) = \frac{1}{2}\log\left(\frac{1+x}{1-x}\right)$. The domain is the open interval $(-1, 1)$.

The inverse hyperbolic tangent can be expressed in terms of related functions (with the principal-branch log and square root):

$$\operatorname{atanh}(z) = \frac{1}{2}\log\left(\frac{1+z}{1-z}\right) = \frac{1}{2}\left[\log(1+z) - \log(1-z)\right] = \frac{1}{i}\operatorname{atan}(iz)$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \leq x \leq 6$ (blue axis), $-6 \leq y \leq 6$ (red axis), $-10 \leq z \leq 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Atanh(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Atanh('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '0.5'
>>> \mathrm{d}x = dec.atanh(x); mx = mpm.atanh(x); ix = ipm.atanh(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  5.4930614433405484569762261846126285232 37E-1
mpm:  5.4930614433405484569762261846126285232 37e-1
ipm:  5.4930614433405484569762261846126285232 37e-1 (2.09e-39%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '0.5'
>>> fx = fpm.atanh(x); gx = gmp.atanh(x); ax = apm.atanh(x)
>>> mpm.show([fx, gx, ax])
fpm:  5.49306144334055E-01
gmp:  5.4930614433405484569762261846126285232 37E-01
apm:  5.4930614433405484569762261846126285232 37e-1 (2.09e-39%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '2 + 1.5E+2j'
>>> \mathrm{d}z = dec.atanh(z); mz = mpm.atanh(z); iz = ipm.atanh(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 8.8869141126887266889E-5              + 1.5641309437602554673E+0 2j
mpm: 8.8869141126887266889e-5              + 1.5641309437602554673e+0 2j
ipm: 8.8869141126887268292e-5 (3.812e-15%) + 1.5641309437602554673e+0 (5.415e-20%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '2 + 1.5E+2j'
>>> fz = fpm.atanh(z); gz = gmp.atanh(z); az = apm.atanh(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 8.88691411268873E-05                 + 1.56413094376026E+00 2j
gmp: 8.8869141126887266889E-05            + 1.5641309437602554673E+00 2j
apm: 8.8869141126887266883e-5 (4.73e-17%) + 1.5641309437602554673e+0 (1.083e-19%)j
```

3.10.4 Inverse hyperbolic cotangent, $\operatorname{acoth}(x)$

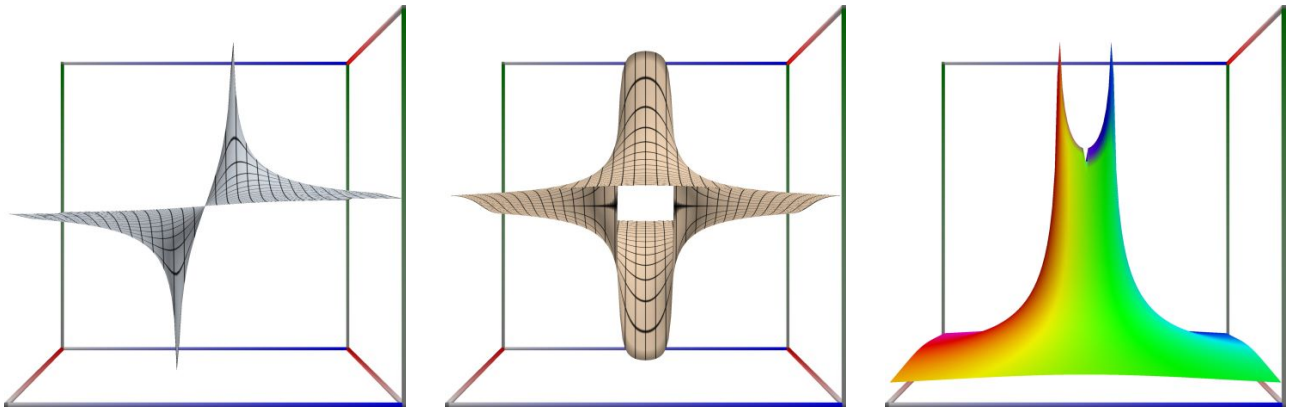
`ctx.acoth(`x`)`

Returns the inverse hyperbolic cotangent of x, $\operatorname{acoth}(x)$. See also Wikipedia [1263], MathWorld [889], NIST [487], Ehrhardt [297] (4.2.7), Mpmath [574].

The real inverse hyperbolic cotangent can be defined as $\operatorname{acoth}(x) = \frac{1}{2}\log\left(\frac{x+1}{x-1}\right)$. The domain is the union of the open intervals $(-\infty, -1)$ and $(1, +\infty)$.

The complex inverse hyperbolic cotangent can be expressed in terms of related functions (with the principal-branch log and square root):

$$\operatorname{acoth}(z) = \frac{1}{2}\log\left(\frac{z+1}{z-1}\right) = \frac{1}{2}\left[\log\left(1+\frac{1}{z}\right) - \log\left(1-\frac{1}{z}\right)\right] = \frac{1}{i}\operatorname{acot}(-iz).$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Acoth(0.5)
ereal('5.2359877559829887307E-1')
>>> ereal.Acoth('0.51')
ereal('5.3518479027559984754E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '1.5'
>>> \mathrm{d}x = dec.acoth(x); mx = mpm.acoth(x); ix = ipm.acoth(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  8.0471895621705018730037966661309381976 28E-1
mpm:  8.0471895621705018730037966661309381976 28e-1
ipm:  8.0471895621705018730037966661309381976 28e-1 (2.853e-39%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '1.5'
>>> fx = fpm.acoth(x); gx = gmp.acoth(x); ax = apm.acoth(x)
>>> mpm.show([fx, gx, ax])
fpm:  8.04718956217050E-01
gmp:  8.0471895621705018730037966661309381976 28E-01
apm:  8.0471895621705018730037966661309381976 28e-1 (7.133e-40%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '2 + 1.5E+2j'
>>> \mathrm{d}z = dec.acoth(z); mz = mpm.acoth(z); iz = ipm.acoth(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 8.8869141126887266889E-5              - 6.6653830346411519558E-3j
mpm: 8.8869141126887266889e-5              - 6.6653830346411519558e-3j
ipm: 8.8869141126887267011e-5 (7.15e-16%) - 6.6653830346411519558e-3 (-1.489e-19%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '2 + 1.5E+2j'
>>> fz = fpm.acoth(z); gz = gmp.acoth(z); az = apm.acoth(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 8.88691411268873E-05                  - 6.66538303464115E-03j
gmp: 8.8869141126887266889E-05             - 6.6653830346411519558E-03j
apm: 8.8869141126887266888e-5 (1.28e-18%) - 6.6653830346411519558e-3 (-1.986e-19%)j
```

3.10.5 Inverse hyperbolic secant, $\operatorname{asech}(x)$

`ctx.asech`(x)

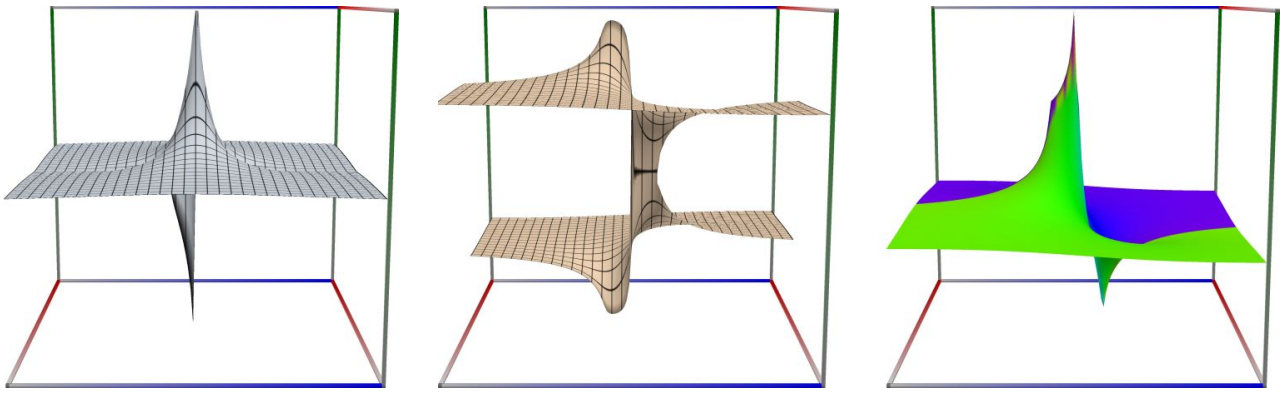
where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the inverse hyperbolic secant of x, $\operatorname{asech}(x)$. See also Wikipedia [1263], MathWorld [890], NIST [487], Ehrhardt [297] (4.2.12), Mpmath [575].

The inverse hyperbolic secant can be defined as $\operatorname{asech}(x) = \log\left(\frac{1}{x} + \sqrt{\frac{1}{x^2} - 1}\right)$. The domain is the semi-open interval $(0, 1]$.

The inverse hyperbolic secant can be expressed in terms of related functions (with the principal-branch log and square root):

$$\operatorname{asech}(z) = \log\left(\frac{1}{z} + \sqrt{\frac{1}{z} + 1}\sqrt{\frac{1}{z} - 1}\right)$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Asech(0.5)
ereal('5.2359877559829887307E-1')
>>> ereal.Asech('0.51')
ereal('5.3518479027559984754E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '0.5'
>>> \mathrm{d}x = dec.asech(x); mx = mpm.asech(x); ix = ipm.asech(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  1.31695789692481670862504634730796844402 7E+0
mpm:  1.31695789692481670862504634730796844402 7e+0
ipm:  1.31695789692481670862504634730796844402 7e+0 (8.717e-40%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '0.5'
>>> fx = fpm.asech(x); gx = gmp.asech(x); ax = apm.asech(x)
>>> mpm.show([fx, gx, ax])
fpm:  1.31695789692482E+00
gmp:  1.31695789692481670862504634730796844402 7E+00
apm:  1.31695789692481670862504634730796844402 7e+0 (8.717e-40%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '2 + 1.5E+2j'
>>> \mathrm{d}z = dec.asech(z); mz = mpm.asech(z); iz = ipm.asech(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 6.6654323630640601125E-3              - 1.5707074556797408039E+0j
mpm: 6.6654323630640601125e-3              - 1.5707074556797408039e+0j
ipm: 6.6654323630640601131e-3 (5.053e-17%) - 1.5707074556797408039e+0 (-5.393e-20%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '2 + 1.5E+2j'
>>> fz = fpm.asech(z); gz = gmp.asech(z); az = apm.asech(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 6.66543236306406E-03                  - 1.57070745567974E+00j

apm: 6.6654323630640601124e-3 (1.787e-18%) - 1.5707074556797408039e+0 (-1.079e-19%)j
```

3.10.6 Inverse Hyperbolic Cosecant, $\operatorname{acsch}(x)$

`ctx.acsch`(x)

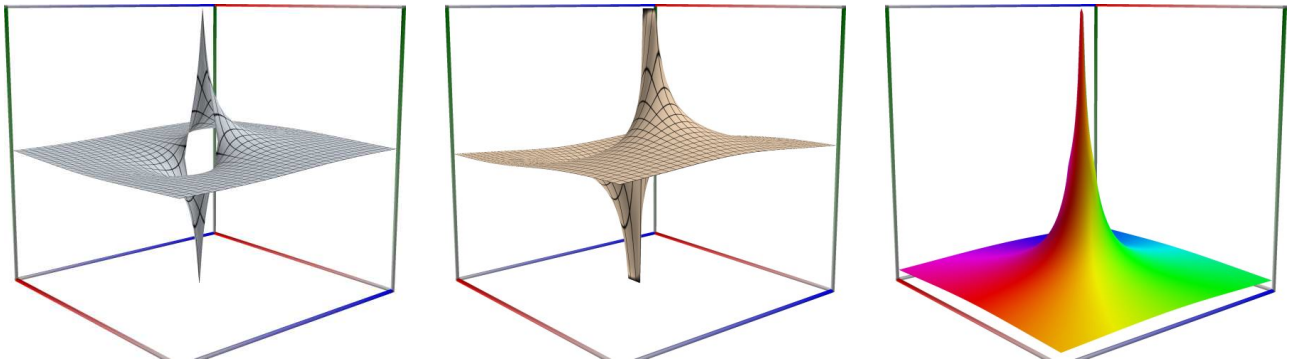
where `ctx` is `math53`, `mathc53`, `ctxcpp` or `ctxflint`.

Returns the inverse hyperbolic cosecant of x, $\operatorname{acsch}(x)$. See also Wikipedia [1263], MathWorld [887], NIST [441], Ehrhardt [297] (4.2.10), Mpmath [572].

The real inverse hyperbolic cosecant can be defined as $\operatorname{acsch}(x) = \log\left(\frac{1}{x} + \sqrt{\frac{1}{x^2} + 1}\right)$. The domain is the real line with 0 removed.

The complex inverse hyperbolic cosecant can be expressed in terms of related functions (with the principal-branch log and square root):

$$\operatorname{acsch}(z) = \log\left(\frac{1}{z} + \sqrt{\frac{1}{z^2} + 1}\right)$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \leq x \leq 6$ (blue axis), $-6 \leq y \leq 6$ (red axis), $-10 \leq z \leq 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Acsch(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Acsch('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '1.5'
>>> \mathrm{d}x = dec.acsch(x); mx = mpm.acsch(x); ix = ipm.acsch(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  6.2514511725041668763425167322610240703 42E-1
mpm:  6.2514511725041668763425167322610240703 42e-1
ipm:  6.2514511725041668763425167322610240703 42e-1 (1.01e-38%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '1.5'
>>> fx = fpm.acsch(x); gx = gmp.acsch(x); ax = apm.acsch(x)
>>> mpm.show([fx, gx, ax])
fpm:  6.25145117250417E-01
gmp:  6.2514511725041668763425167322610240703 42E-01
apm:  6.2514511725041668763425167322610240703 42e-1 (9.181e-40%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '2 + 1.5E+2j'
>>> \mathrm{d}z = dec.acsch(z); mz = mpm.acsch(z); iz = ipm.acsch(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 6.6654323630640601125E-3              - 1.5707074556797408039E+0j
mpm: 6.6654323630640601125e-3              - 1.5707074556797408039e+0j
ipm: 6.6654323630640601131e-3 (5.053e-17%) - 1.5707074556797408039e+0 (-5.393e-20%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '2 + 1.5E+2j'
>>> fz = fpm.acsch(z); gz = gmp.acsch(z); az = apm.acsch(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 6.66543236306406E-03                  - 1.57070745567974E+00j
gmp: 6.6654323630640601125E-03             - 1.5707074556797408039E+00j
apm: 6.6654323630640601124e-3 (1.787e-18%) - 1.5707074556797408039e+0 (-1.079e-19%)j
```

3.11 Factorials, Gamma and related functions

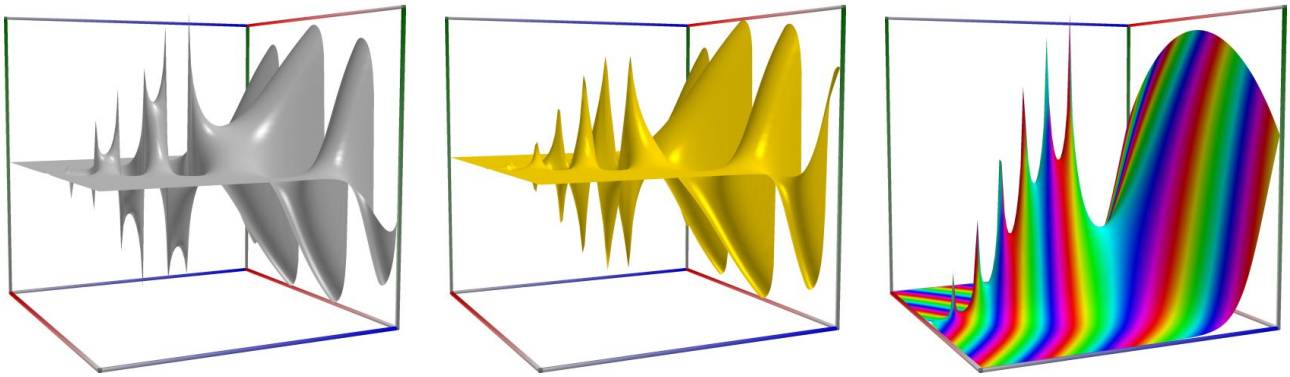
3.11.1 Gamma function, $\Gamma(x)$

`ctx.gamma(`x`)`

where `ctx` is `math53`, `mathc53`, `ctxboost`, `ctxflint`.

Returns the gamma function $\Gamma(x) = \int_0^\infty t^{x-1} e^{-t}\, \mathrm{d}t$, for any real or complex x with $\Re(x) > 0$ and for $\Re(x) < 0$ by analytic continuation.

See also Wikipedia [1260], MathWorld [886], NIST [22], BoostMath [101], Ehrhardt [297] (3.5.1.1), Ehrhardt [297] (4.2.38), Flint [741], Flint [731], Mpmath [591].



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Gamma(0.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.Gamma('0.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '10.5'
>>> \mathrm{d}x = dec.gamma(x); mx = mpm.gamma(x); ix = ipm.gamma(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  1.133278388948785567334574165588892475560E+6
mpm:  1.133278388948785567334574165588892475560e+6
ipm:  1.133278388948785567334574165588892475560e+6 (1.062e-39%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '10.5'
>>> fx = fpm.gamma(x); gx = gmp.gamma(x); ax = apm.gamma(x)
>>> mpm.show([fx, gx, ax])
fpm:  1.1332783894879E+06
gmp:  1.133278388948785567334574165588892475560E+06
apm:  1.133278388948785567334574165588892475560e+6 (1.062e-39%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '10.2 + 1.5E-2j'
```

(continues on next page)

(continued from previous page)

```
>>> \mathrm{d}z = dec.gamma(z); mz = mpm.gamma(z); iz = ipm.gamma(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 5.7016098526432799845E+5              + 1.9443478604345155482E+4j

ipm: 5.7016098526432799844e+5 (1.558e-18%) + 1.9443478604345155482e+4 (1.713e-18%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '10.2 + 1.5E-2j'
>>> fz = fpm.gamma(z); gz = gmp.gamma(z); az = apm.gamma(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 5.701609852643l6E+05                  + 1.94434786043447E+04j
gmp: 5.7016098526432799845E+05             + 1.9443478604345155482E+04j
apm: 5.7016098526432799845e+5 (4.284e-18%) + 1.9443478604345155482e+4 (8.065e-18%)j
```

Arguments can also be large. Note that the gamma function grows very quickly:

```
>>> from xlcalcnet import mp
>>> mp.dps = 25; mp.pretty = True
>>> mp.dps = 15
>>> gamma(10**20)
1.9328495143101e+1956570551809674817225
```

3.11.2 Auxiliary function $\Gamma(x+1)-1$

`ctx.gamma1pm1`(z)

where `ctx` is `math53`, `ctxcpp`, `ctxboost` or `ctxflint`.

Returns $\Gamma(1+x)-1$, accurate also for x near 0.

See also Wikipedia [1260], MathWorld [886], NIST [22], BoostMath [101], Ehrhardt [297] (3.5.1.2)., Flint [741], Flint [731].

3.11.3 Log-gamma function, $\log\Gamma(x)$

`ctx.lgamma`(x)

where `ctx` is `math53`, `mathc53`, `ctxboost`, `ctxflint`.

Returns the principal branch of the log-gamma function, $\log|\Gamma(x)|$ for $x \neq 0, -1, -2, \ldots$. If $x < 0$, the logarithmic form of the reflection formula is used.

See also: https://en.wikipedia.org/wiki/Gamma_function#Log-gamma_function

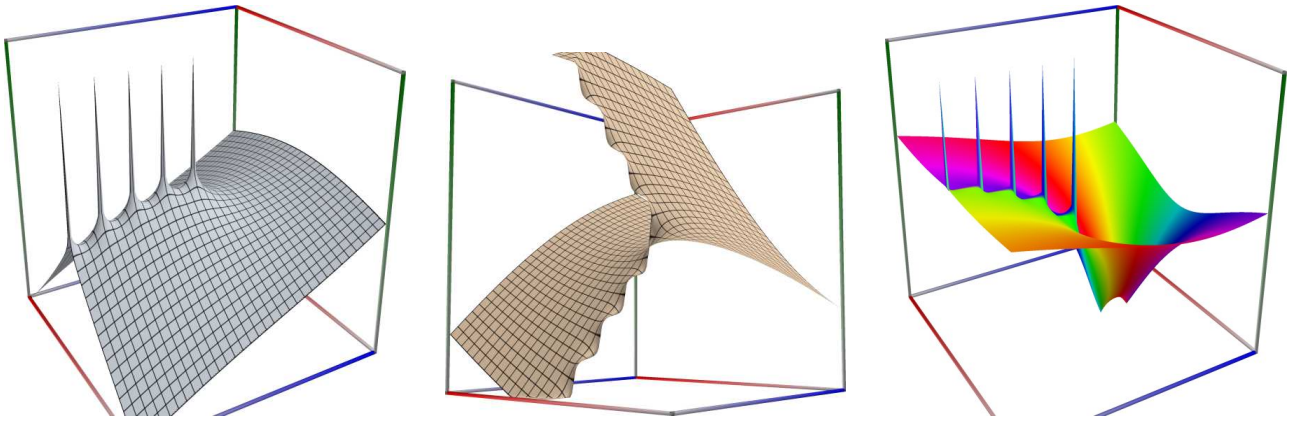
See also: https://mathworld.wolfram.com/LogGammaFunction.html

See also Wikipedia [1271], MathWorld [894], BoostMath [102], Ehrhardt [297] (3.5.1.5), Ehrhardt [297] (4.2.43), Flint [741], Flint [731], Mpmath [597].

Unlike $\log(\Gamma(z))$, which has infinitely many complex branch cuts, the principal log-gamma function only has a single branch cut along the negative half-axis. The principal branch continuously matches the asymptotic Stirling expansion

$$\log\Gamma(z) \sim \frac{\log(2\pi)}{2} + \left(z - \frac{1}{2}\right)\log(z) - z + O(z^{-1}).$$

The real parts of both functions agree, but their imaginary parts generally differ by $2n\pi$ for some $n \in \mathbb{Z}$. They coincide for $z \in \mathbb{R}, z > 0$.



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \leq x \leq 6$ (blue axis), $-6 \leq y \leq 6$ (red axis), $-10 \leq z \leq 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.LogGamma(1.5)
ereal('5.235987755982988730 7E-1')
>>> ereal.LogGamma('1.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '10.5'
>>> \mathrm{d}x = dec.loggamma(x); mx = mpm.loggamma(x); ix = ipm.loggamma(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  1.3940625219403763633161237887971849479 80E+1
mpm:  1.3940625219403763633161237887971849479 80e+1
ipm:  1.3940625219403763633161237887971849479 80e+1 (6.588e-40%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
```

(continues on next page)

(continued from previous page)

```
>>> mpm.dps = 40; x = '10.5'
>>> fx = fpm.loggamma(x); gx = gmp.loggamma(x); ax = apm.loggamma(x)
>>> mpm.show([fx, gx, ax])
fpm:  1.39406252194038E+01
gmp:  1.3940625219403763633161237887971849479 80E+01
apm:  1.3940625219403763633161237887971849479 80e+1 (1.318e-39%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '10.2 + 1.5E-2j'
>>> \mathrm{d}z = dec.loggamma(z); mz = mpm.loggamma(z); iz = ipm.loggamma(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 1.3254255156536136589E+1              + 3.4088524535204731293E-2j
mpm: 1.3254255156536136589e+1              + 3.4088524535204731293e-2j
ipm: 1.3254255156536136589e+1 (2.045e-19%) + 3.4088524535204731293e-2 (1.553e-19%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '10.2 + 1.5E-2j'
>>> fz = fpm.loggamma(z); gz = gmp.loggamma(z); az = apm.loggamma(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 1.32542551565361E+01                 + 3.40885245352047E-02j
gmp: 1.3254255156536136589E+01            + 3.4088524535204731293E-02j
apm: 1.3254255156536136589e+1 (4.09e-19%) + 3.4088524535204731293e-2 (6.989e-19%)j
```

Note the imaginary parts for negative arguments:

```
>>> from xlcalcnet import mpm
>>> mpm.dps = 25; mpm.pretty = True
>>> mpm.loggamma(-0.5); mpm.loggamma(-1.5); mpm.loggamma(-2.5)
(1.2655121234846453964889 46 - 3.1415926535897932384626 43j)
(0.8600470153764810145109327 - 6.2831853071795864769252 87j)
(-0.0562437164976740506725 9453 - 9.4247779607693797153879 3j)
```

Huge arguments are permitted:

```
>>> from xlcalcnet import dec, mpr, ivr, ivc
>>> ivr.dps = 25; ivr.pretty = True
>>> loggamma('1e3000')
6.9067552789821370520539 74e+3003
>>> loggamma('1e1000000000000000000000')
2.3025850929940456840079 91e+1000000000000000000020
>>> loggamma('1e300j')
(-1.5707963267948966192313 22e+300 + 6.8977552789821370520539 74e+302j)
>>> loggamma('1e3000j')
(-1.5707963267948966192313 22e+3000 + 6.9067552789821370520539 74e+3003j)
```

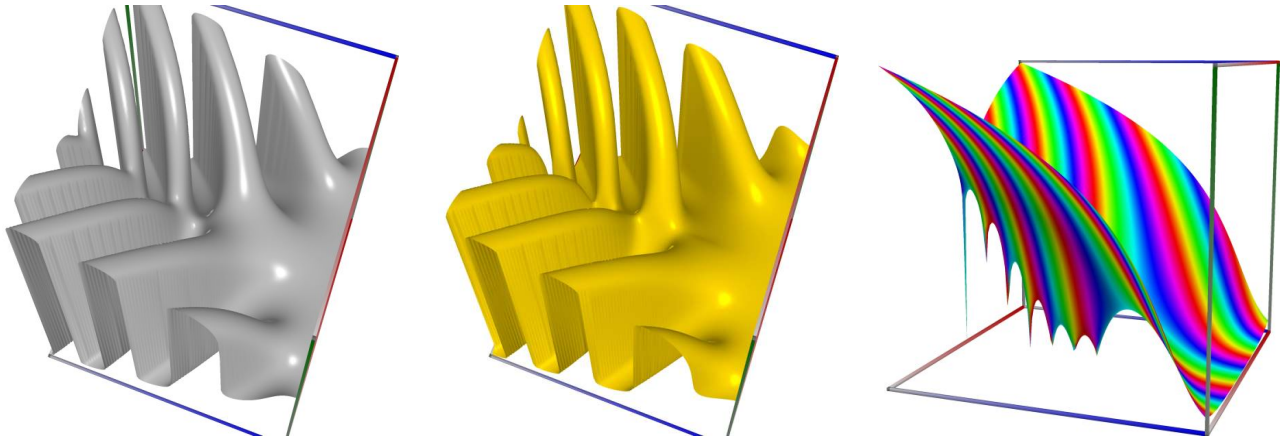
3.11.4 Reciprocal Gamma function, $1/\Gamma(x)$

`ctx.rgamma(x)`

where `ctx` is `math53`, `mathc53`, `ctxboost`, `ctxflint`.

Returns the reciprocal of gamma function x, $1/\Gamma(x)$, which is an entire function with simple zeros at the points $x = 0$ and the negative integers.

See also Wikipedia [1270], MathWorld [896], Ehrhardt [297] (3.5.1.8), Ehrhardt [297] (4.2.51), Flint [741], Flint [731].



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \le x \le 6$ (blue axis), $-6 \le y \le 6$ (red axis), $-10 \le z \le 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.RGamma(1)
1.0
>>> ereal.RGamma(4)
0.16666666666666666666666667
>>> ereal.RGamma(0); ereal.RGamma(-1)
0.0
0.0
>>> ereal.RGamma(1000)
2.4851681432667848627835 96e-2565
>>> ereal.RGamma('inf')
0.0
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '10.5'
>>> \mathrm{d}x = dec.rgamma(x); mx = mpm.rgamma(x); ix = ipm.rgamma(x)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  8.8239572002038009055094026242 56928377655E-7
mpm:  8.8239572002038009055094026242 56928377655e-7
ipm:  8.8239572002038009055094026242 56928377655e-7 (1.861e-39%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '10.5'
>>> fx = fpm.rgamma(x); gx = gmp.rgamma(x); ax = apm.rgamma(x)
>>> mpm.show([fx, gx, ax])
fpm:  8.8239572002038 0E-07
gmp:  8.8239572002038009055094026242 56928377655E-07
apm:  8.8239572002038009055094026242 56928377655e-7 (6.203e-40%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '10.2 + 1.5E-2j'
>>> \mathrm{d}z = dec.rgamma(z); mz = mpm.rgamma(z); iz = ipm.rgamma(z)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 1.7518533332561467304E-6              - 5.9741237445991417084E-8j
mpm: 1.7518533332561467304e-6              - 5.9741237445991417084e-8j
ipm: 1.7518533332561467304e-6 (4.749e-18%) - 5.9741237445991417085e-8 (-4.902e-18%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '10.2 + 1.5E-2j'
>>> fz = fpm.rgamma(z); gz = gmp.rgamma(z); az = apm.rgamma(z)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 1.75185333325618E-06                  - 5.97412374459925E-08j
gmp: 1.7518533332561467304E-06             - 5.9741237445991417084E-08j
apm: 1.7518533332561467304e-6 (4.242e-18%) - 5.9741237445991417084e-8 (-7.521e-18%)j
```

This function evaluates to zero at the poles of the gamma function, $z = 0, -1, -2, \ldots$.

```
>>> from xlcalcnet import dec, mpr, ivr, ivc
>>> ivr.dps = 25; ivr.pretty = True
>>> rgamma(1)
1.0
>>> rgamma(4)
0.16666666666666666666666667
>>> rgamma(0); rgamma(-1)
0.0
0.0
>>> rgamma(1000)
2.4851681432667848627835960e-2565
>>> rgamma(inf)
0.0
```

3.11.5 Factorial, $x!$

`ctx.factorial(x)`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns $x!$, the factorial of x. For integers $x \geq 0$, we have $x! = 1 \cdot 2 \cdots (x-1) \cdot x$ and for real or complex x we have $x! = \Gamma(x+1)$.

See also Wikipedia [1258], MathWorld [884], BoostMath [99], Ehrhardt [297] (3.5.4.1), Flint [741], Flint [731], Mpmath [589].

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Factorial(3)
ereal('5.2359877559829887307E-1')
>>> ereal.Factorial('0.51')
ereal('5.351847902755998475 4E-1')
```

3.11.6 Double factorial, $x!!$

`ctx.double_factorial(x)`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns $x!!$, the double factorial of x.

$$n!! = \begin{cases} 1 \cdot 3 \cdot 5 \cdots n & \text{if } n \text{ is odd.} \\ 2 \cdot 4 \cdot 6 \cdots n & \text{if } n \text{ is even.} \end{cases}$$

and more generally by

$$x!! = 2^{x/2} \left(\frac{\pi}{2}\right)^{(\cos(\pi x)-1)/4} \Gamma\left(\frac{x}{2}+1\right).$$

See also Wikipedia [1278], MathWorld [920], BoostMath [118], Ehrhardt [297] (3.5.4.2), Flint [741], Flint [731], Mpmath [609].

See also http://dlmf.nist.gov/5.4.E2

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.DFactorial(3)
ereal('5.235987755982988730 7E-1')
>>> ereal.DFactorial('0.51')
ereal('5.3518479027559984754E-1')
```

3.11.7 Rising factorial $a^{\overline{n}} = (a)_n$

`ctx.rising_factorial(a, n)`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the rising factorial , $a^{\overline{n}} = (a)_n = a(a+1)\cdots(a+n-1) = \dfrac{\Gamma(a+n)}{\Gamma(a)}$, where the rightmost expression is valid for nonintegral n. By convention $(a)_0 = 1$. Note that in Wikipedia [1259], the Pochhammer symbol $(a)_n$ is used for the falling factorial (as is common in combinatorics), whereas in this manual we follow the convention in MathWorld [897], Abramowitz and Stegun. [4], BoostMath [110], Ehrhardt [297], and the literature of special functions (in particular the hypergeometric functions), using it for the rising factorial.

If a or $a+n$ are negative integers or zero special care must be taken: If only a is a negative integer then the result is zero. If $a+n$ is also a negative integer then the Pochhammer symbol is computed from the limiting form of the Γ reflection formula $(a)_n = (-1)^n \dfrac{\Gamma(1-a)}{\Gamma(1-a-n)}$, and otherwise the function is undefined.

See also Wikipedia [1259], MathWorld [897], BoostMath [110], Ehrhardt [297] (3.5.4.6), Flint [741], Flint [731], Mpmath [601].

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Pochhammer(13, 7)
ereal('5.235987755982988730 7E-1')
>>> ereal.RisingFactorial(12.6, '4.51')
ereal('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; x = '20.4'; n = '10.4'
>>> \mathrm{d}x = dec.rf(x, n); mx = mpm.rf(x, n); ix = ipm.rf(x, n)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  3.34337297397901888955468000837177197965 3E+14
mpm:  3.34337297397901888955468000837177197965 2e+14
ipm:  3.34337297397901888955468000837177197965 5e+14 (1.836e-37%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; x = '20.4'; n = '10.4'
>>> fx = fpm.rf(x, n); gx = gmp.rf(x, n); ax = apm.rf(x, n)
>>> mpm.show([fx, gx, ax])
fpm:  3.343372973979 01E+14
gmp:  3.34337297397901888955468000837177197965 2E+14
apm:  3.34337297397901888955468000837177197965 4e+14 (3.73e-37%)
```

The following example with complex input shows that the relative error can be high in double precision:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 20; z = '20.2 + 1.5E-2j'; n = '10.7 + 2.3E-1j'
>>> \mathrm{d}z = dec.rf(z, n); mz = mpm.rf(z, n); iz = ipm.rf(z, n)
>>> mpm.show([\mathrm{d}z, mz, iz], aligned=True)
dec: 5.9977312704618499868E+14              + 6.0755212828478581691E+14j
mpm: 5.9977312704618499868e+14              + 6.0755212828478581692e+14j
ipm: 5.9977312704618499868e+14 (2.178e-17%) + 6.0755212828478581692e+14 (2.292e-17%)j

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 20; z = '20.2 + 1.5E-2j'; n = '10.7 + 2.3E-1j'
>>> fz = fpm.rf(z, n); gz = gmp.rf(z, n); az = apm.rf(z, n)
>>> mpm.show([fz, gz, az], aligned=True)
fpm: 5.99773127046176E+14                   + 6.07552128284776E+14j
gmp: 5.9977312704618499868E+14              + 6.0755212828478581692E+14j
apm: 5.9977312704618499868e+14 (4.245e-17%) + 6.0755212828478581692e+14 (4.442e-17%)j
```

Evaluation is supported for arbitrary arguments:

```
>>> from xlcalcnet import mp
>>> mp.dps = 25; mp.pretty = True
>>> mp.rf(2+3j, 5.5)
(-7202.03920483347 - 3777.58810701527j)
```

3.11.8 Falling factorial, $(a)^{\underline{n}} = (a-n+1)^{\overline{n}}$

`ctx.falling_factorial`(a, n)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the falling factorial of a and n, $a^{\underline{n}} = a(a-1)\cdots(a-n+1) = \dfrac{\Gamma(a+1)}{\Gamma(a+1-n)}$, where the rightmost expression is valid for nonintegral n.

The falling factorial $(a)^{\underline{n}}$ is related to the rising factorial $(a)^{\overline{n}}$ by $(a)^{\underline{n}} = (a-n+1)^{\overline{n}}$.

See also Wikipedia [1259], MathWorld [885], BoostMath [100], Mpmath [590].

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.FallingFactorial(13, 7)
ereal('5.235987755982988730 7E-1')
>>> ereal.FallingFactorial(12.6, '4.51')
ereal('5.351847902755998475 4E-1')
```

3.11.9 Ratio of gamma functions, $\Gamma(a)/\Gamma(b)$

`ctx.gamma_ratio`(a, b)

where `ctx` is `math53`, `ctxcpp`, `ctxboost` or `ctxflint`.

This functions returns the ratio of gamma functions in the form

$$\frac{\Gamma(a)}{\Gamma(b)}$$

See also BoostMath [126], Ehrhardt [297] (3.5.5).

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; a = '20.4'; b = '10.4'
>>> \mathrm{d}x = dec.gamma_ratio(a, b); mx = mpm.gamma_ratio(a, b); ix = ipm.gamma_ratio(a, b)
>>> mpm.show([\mathrm{d}x, mx, ix])
dec:  4.4500053833434933493760000000000000000E+11
mpm:  4.4500053833434933493760000000000000000e+11
ipm:  4.4500053833434933493760000000000000001e+11 (7.871e-38%)

>>> from xlcalcnet import mpm, fpm, gmp, apm
>>> mpm.dps = 40; a = '20.4'; b = '10.4'
>>> fx = fpm.gamma_ratio(a, b); gx = gmp.gamma_ratio(a, b); ax = apm.gamma_ratio(a, b)
>>> mpm.show([fx, gx, ax])
fpm:  4.45000538334346E+11
gmp:  4.4500053833434933493760000000000000000E+11

```

3.11.10 Gamma-delta ratio, $\Gamma(a)/\Gamma(a+\delta)$

`ctx.gamma_delta_ratio`(x, *delta*)

where `ctx` is `math53`, `ctxcpp`, `ctxboost` or `ctxflint`.

Returns the tgamma_ratio function of z and m. See also BoostMath [126].

Returns $\Gamma(x)/\Gamma(x+d)$, accurate even for $|d| << |x|$.

This functions returns the ratio of gamma functions in the form

$$\frac{\Gamma(a)}{\Gamma(a+\delta)}$$

Note that the result is calculated accurately even when δ is small compared to a: indeed even if $a + \delta \approx a$. The function is typically used when a is large and δ is very small.

Note: ctxboost.TgammaDeltaRatio(x, d)

Returns $\dfrac{\Gamma(x)}{\Gamma(x+d)}$, accurate also for $|d| \ll |x|$.

See also BoostMath [126], Ehrhardt [297] (3.5.5).

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; a = '2000.4'; d = '0.0004'
>>> \mathrm{d}z = dec.gamma_delta_ratio(a, d); mz = mpm.gamma_delta_ratio(a, d)
>>> iz = ipm.gamma_delta_ratio(a, d); fz = fpm.gamma_delta_ratio(a, d)
>>> gz = gmp.gamma_delta_ratio(a, d); az = apm.gamma_delta_ratio(a, d)
>>> mpm.show([\mathrm{d}x, mx, ix, fx, gx, ax])
dec:  9.969642761288672131226497458238654348190E-1

```

3.11.11 Beta function, $B(a,b) = \Gamma(a)\Gamma(b)/\Gamma(a+b)$

`ctx.beta`(a, b)

where `ctx` is `math53`, `ctxcpp`, `ctxboost` or `ctxflint`.

Returns the beta function $B(x,y) = \dfrac{\Gamma(x)\Gamma(y)}{\Gamma(x+y)} = \displaystyle\int_0^1 t^{x-1}(1-t)^{y-1}\,\mathrm{d}t$.

See also Wikipedia [1254], MathWorld [882], NIST [21], BoostMath [95], Ehrhardt [297] (3.5.3.1), Mpmath [587].

An example with real input:

```
>>> from xlcalcnet import dec, mpm, ipm
>>> mpm.dps = 40; a = '20.4'; b = '10.4'
>>> \mathrm{d}x = dec.beta(a, b); mx = mpm.beta(a, b); ix = ipm.beta(a, b)
>>> mpm.show([\mathrm{d}x, mx, ix])

```

3.11.12 Binomial coefficient, ${}_nC_k = (k \cdot B(k, n-k+1))^{-1}$

`ctx.binomial`(n, k)

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns the binomial coefficient of n and k, ${}_nC_k = \binom{n}{k} = \dfrac{n!}{k!(n-k)!}$, for $k \geq 0$. More generally, the binomial coefficient is a well-defined function of arbitrary real or complex n and k, via the gamma function.

$$ {}_nC_k = \binom{n}{k} = \frac{n!}{k!(n-k)!} = \frac{\Gamma(n+1)}{\Gamma(k+1)\Gamma(n-k+1)} = \frac{1}{k \cdot B(k, n-k+1)}. $$

See also Wikipedia [1255], MathWorld [883], NIST [485], BoostMath [96], Ehrhardt [297] (3.5.4.4), Flint [741], Flint [731], Mpmath [588].

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.Binomial(13, 7)
ereal('5.235987755982988730 7E-1')
>>> ereal.Binomial(12.6, '4.51')
ereal('5.3518479027559984754E-1')
```

3.12 Miscellaneous functions

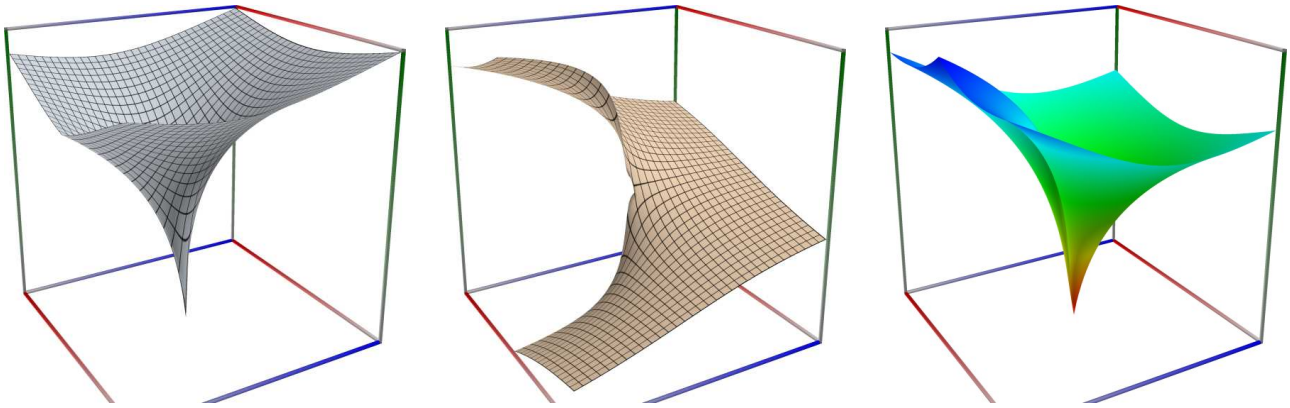
3.12.1 Lambert W function, $W_0(x)$

`ctx.lambert_w0(x)`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns $W_0(x)$, the real-valued principal branch of the Lambert W function for $x > -1/e$, with $W_0(x) \geq -1$ for $x < 0$. The Lambert W function is defined as the solution of $x = W(x)\exp(W(x))$.

See also Wikipedia [1264], MathWorld [893], NIST [489], BoostMath [106], Corless *et al.* [185], Ehrhardt [297] (3.10.15), Flint [746], Flint [736], Mpmath [596].



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \leq x \leq 6$ (blue axis), $-6 \leq y \leq 6$ (red axis), $-10 \leq z \leq 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.LambertW(3.4)
ereal('5.2359877559829887307E-1')
>>> ereal.LambertW(13.4)
ereal('5.3518479027559984754E-1')
```

Basic examples

The Lambert W function is the inverse of $w\exp(w)$:

```
>>> from xlcalcnet import *
>>> mp.dps = 25; mp.pretty = True
>>> w = lambertw(1)
>>> w
0.56714329040978387299996866
>>> w*exp(w)
1.0
```

Any branch gives a valid inverse:

```
>>> w = lambertw(1, k=3)
>>> w
(-2.8535817554090378072068189 + 17.113535539412145912607834j)
>>> w = lambertw(1, k=25)
>>> w
(-5.0470204642215697093786864 + 155.47638609494158671620664j)
>>> chop(w*exp(w))
1.0
```

3.12.2 Lambert W function, $W_{-1}(x)$

`ctx.lambert_wm1(x)`

where `ctx` is `math53`, `ctxboost` or `ctxflint`.

Returns $W_{-1}(x)$, the second real-valued, non-principal, branch of the Lambert W function for $-1/e < x < 0$, with $W_{-1}(x) \leq -1$ for $x < 0$. The Lambert W function is defined as the solution of $x = W(x)\exp(W(x))$, Flint [746], Flint [736].

See also Wikipedia [1264], MathWorld [893], NIST [489], BoostMath [106], Ehrhardt [297] (3.10.15), Mpmath [596].

An example in Python

```
>>> from xlcalcnet import ereal
>>> ereal.LambertW1(0.2)
ereal('5.235987755982988730 7E-1')
>>> ereal.LambertW1(0.21)
ereal('5.351847902755998475 4E-1')
```

Basic examples

The Lambert W function is the inverse of $w\exp(w)$:

```
>>> from xlcalcnet import *
>>> mp.dps = 25; mp.pretty = True
>>> w = lambertw(1)
>>> w
0.56714329040978387299997
>>> w*exp(w)
1.0
```

Any branch gives a valid inverse:

```
>>> w = lambertw(1, k=3)
>>> w
(-2.8535817554090378072068 19 + 17.113535539412145912607 83j)
>>> w = lambertw(1, k=25)
>>> w
(-5.0470204642215697093786 86 + 155.4763860949415867162066j)
>>> chop(w*exp(w))
1.0
```

3.12.3 Lambert W (general case)

`ctx.lambert_wk(z, k=0)`

where `ctx` is `math53`, `ctxboost`, `ctxflint`.

Returns the Lambertw function of z.

See also BoostMath [106], Wikipedia [1264], MathWorld [893], NIST [489], Corless *et al.* [185], Ehrhardt [297] (4.2.39), Flint [746], Flint [736], Mpmath [596].

The Lambert W function $W(z)$ is defined as the inverse function of $w\exp(w)$. In other words, the value of $W(z)$ is such that $z = W(z)\exp(W(z))$ for any complex number z.

The Lambert W function is a multivalued function with infinitely many branches $W_k(z)$, indexed by $k \in \mathbb{Z}$. Each branch gives a different solution w of the equation $z = w\exp(w)$. All branches are supported:

- `lambertw(z)` gives the principal solution (branch 0)
- `lambertw(z, k)` gives the solution on branch k

The Lambert W function has two partially real branches: the principal branch ($k = 0$) is real for real $z > -1/e$, and the $k = -1$ branch is real for $-1/e < z < 0$. All branches except $k = 0$ have a logarithmic singularity at $z = 0$.

The definition, implementation and choice of branches is based on Corless *et al.* [185].

An example in Python

```
>>> from xlcalcnet import ecplx
>>> ecplx.LambertW(0.5, 2)
ecplx('5.2359877559829887307E-1')
>>> ecplx.LambertW('0.1')
ecplx('5.3518479027559984754E-1')
```

Basic examples

The Lambert W function is the inverse of $w \exp(w)$:

```
>>> from xlcalcnet import *
>>> mp.dps = 25; mp.pretty = True
>>> w = lambertw(1)
>>> w
0.56714329040978387299997
>>> w*exp(w)
1.0
```

Any branch gives a valid inverse:

```
>>> w = lambertw(1, k=3)
>>> w
(-2.8535817554090378072068 19 + 17.113535539412145912607 83j)
>>> w = lambertw(1, k=25)
>>> w
(-5.0470204642215697093786 86 + 155.476386094941586716206 6j)
>>> chop(w*exp(w))
1.0
```

3.12.4 Arithmetic-geometric mean

`ctx.agm`(*x*, *y=1*)

where `ctx` is `math53`, `mathc53`, `ctxboost` or `ctxflint`.

Returns the arithmetic-geometric mean of $|x|$ and $|y|$. See also Wikipedia [1274], MathWorld [915], Ehrhardt [297] (4.2.1), Ehrhardt [297] (4.2.2), Mpmath [603].

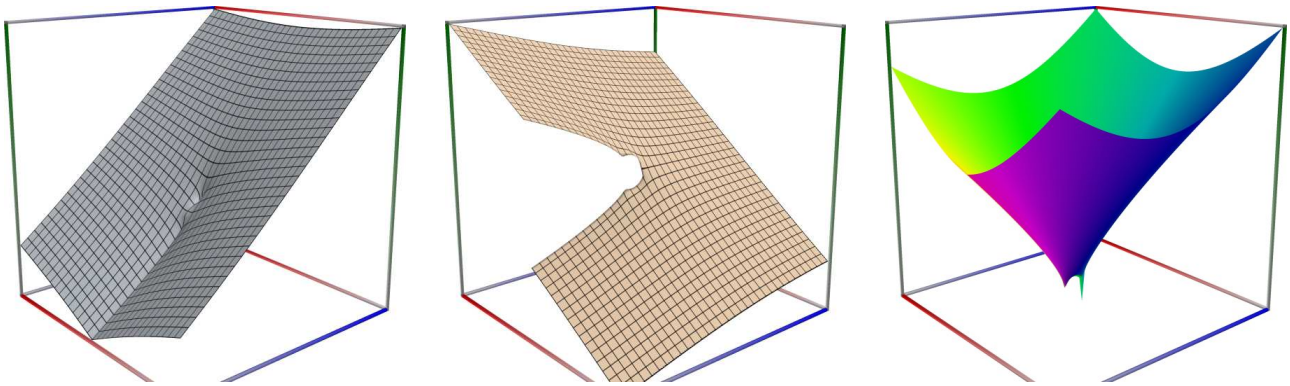
With $a_0 = \max(|x|, |y|)$, $b_0 = \min(|x|, |y|)$ the AGM is calculated using the recurrence formulas

$$a_{n+1} = \tfrac{1}{2}(a_n + b_n), \quad b_{n+1} = \sqrt{a_n b_n}.$$

The sequences converge quadratically to a common limit and $a_n \geq b_n$. The iteration is terminated if $a_n - b_n \leq \epsilon a_n$, where ϵ is less than the square root of the machine epsilon. The result is $(a_n + b_n)/2$.

The function $\mathrm{agm}(a, b)$ can also be expressed in closed form in terms of the complete elliptic integral of the first kind $K(k)$ as

$$\mathrm{agm}(a, b) = \frac{(a+b)\pi}{4K((a-b)/(a+b))}.$$



3D wpf plot: real part (left figure), imaginary part (middle figure) and absolute value with color-coded phase (right figure) of the complex sine function $z = \sin(x + iy)$, with $-6 \leq x \leq 6$ (blue axis), $-6 \leq y \leq 6$ (red axis), $-10 \leq z \leq 10$ (green axis). Function values are *loglog-transformed*.

An example in Python

```
>>> from xlcalcnet import ecplx
>>> ecplx.Agm(0.5, 2)
ecplx('5.235987755982988730 7E-1')
>>> ecplx.Agm('0.1')
ecplx('5.351847902755998475 4E-1')
```

An example with real input:

```
>>> from xlcalcnet import dec, mpm, gmp, fpm, apm
>>> mpm.dps = 40; a = '0.6'; b = '0.3'
>>> \mathrm{d}x = dec.agm(a, b); mx = mpm.agm(a, b); gx = gmp.agm(a, b)
>>> fx = fpm.agm(a, b); ax = apm.agm(a, b)
>>> mpm.show([\mathrm{d}x, mx, gx, fx, ax])

```

CHAPTER

FOUR

STATISTICAL DISTRIBUTIONS

For a general introduction to probability distributions, see: Wikipedia [1138], Wikipedia [1130], Wikipedia [1128], Wikipedia [1145].

The design of this library has been influenced by Bristow *et al.* [159], Witkovsky [1460].

See also Wikipedia [1125] and Abramowitz and Stegun. [4] (from which the following introductory text has been taken, with small edits).

A real-valued function $F(x)$ is termed a (univariate) cumulative distribution function (cdf) or simply distribution function if

1. $F(x)$ is non-decreasing, i.e. $F(x_1) \leq F(x_2)$ for $x_1 \leq x_2$.
2. $F(x)$ is everywhere continuous from the right, i.e. $F(x) = \lim_{\epsilon \to 0+} F(x + \epsilon)$
3. $F(-\infty) = 0, F(\infty) = 1$.

The function $F(x)$ signifies the probability of the event "$X \leq x$", i.e. Pr $\{X \leq x\} = F(x)$, where X is a random variable, and thus describes the cdf of X. The two principle types of distribution functions are termed *discrete* and *continuous*.

Discrete distributions: Discrete distributions are characterized by the random variable X taking on an enumerable number of values $\ldots x_{-1}, x_0, x_1, \ldots$ with point probabilities $p_n = \text{Pr}\{X = x_n\} \geq 0$, which only need to be subject to the restriction $\sum_n p_n = 1$. The corresponding distribution function can then be written as

$$F(x) = \text{Pr}\{X \leq x\} = \sum_{x_n \leq x} p_n,$$

where the summation is over all values of x for which $x_n \leq x$. The set $\{x_n\}$ of values for which $p_n > 0$ is termed the domain of he random variable X. A discrete distribution of a random variable is called a *lattice distribution* if there exists numbers a and $b \neq 0$ such that every possible value of X can be represented in the form $a + bn$ where n takes only integral values.

Continuous distributions: Continuous distributions are characterized by $F(x)$ being continuous. If $F(x)$ is absolutely continuous then $F(x)$ possesses a derivative $F'(x) = f(x)$ and the cdf can be written as

$$F(x) = \text{Pr}\{X \leq x\} = \int_{-\infty}^{x} f(t)\text{d}t.$$

The derivative $f(x)$ is termed the probability density function (pdf), and the values of x for which $f(x) > 0$ make up the domain of the variable X.

The source code for the C# tests in Visual Studio can be found online in the `XlCalcNet` repository or in the corresponding local `XlCalcNet` folder in the file B04_Distributions.cs.

4.1 Introduction to random variables and distributions

4.1.1 Elementary symbolic algebra of random variables

See also https://en.wikipedia.org/wiki/Algebra_of_random_variables.

Considering two random variables X and Y the following algebraic operations are possible:

Addition: $Z = X + Y = Y + X$.

Subtraction: $Z = X - Y = -Y + X$.

Multiplication: $Z = XY = YX$.

Division: $Z = X/Y = X \cdot (1/Y) = (1/Y) \cdot X$.

In all cases, the variable Z resulting from each operation is also a random variable. All commutative and associative properties of conventional algebraic operations are also valid for random variables. If any of the random variables is replaced by a deterministic variable or by a constant value, all the previous properties remain valid.

Simple tranformations, results for pdf and cdf: see Rinne [481], page 217.

This is a summary of some transformations:

Table 1: Some transformations

Transformation $Y = g(X)$	pdf $f_Y(y)$	cdf $F_Y(y)$
$Y = a + bX; \quad a, x \in \mathbb{R}; b \neq 0.$	$= \frac{1}{\lvert b \rvert} f_X\left(\frac{y-a}{b}\right).$	$= \begin{cases} F_X\left(\frac{y-a}{b}\right) & \text{for } b > 0, \\ 1 - F_X\left(\frac{y-a}{b}\right) & \text{for } b < 0. \end{cases}$
$Y = X^r; \quad r \in \mathbb{N}, x \in \mathbb{R}.$	$= \frac{1}{r} y^{\frac{1}{r}-1} f_X\left(\sqrt[r]{y}\right).$	$= F_X\left(\sqrt[r]{y}\right).$
$Y = aX^k; \quad a, k \in \mathbb{R} \setminus \{0\}; \quad x > 0.$	$= \frac{1}{\lvert ka \rvert} \left(\frac{y}{a}\right)^{\frac{1}{k}-1} f_X\left(\sqrt[k]{\frac{y}{a}}\right)$	$= \begin{cases} F_X\left(\sqrt[k]{\frac{y}{a}}\right) & \text{for } a > 0, \\ 1 - F_X\left(\sqrt[k]{\frac{y}{a}}\right) & \text{for } a < 0. \end{cases}$
$Y = a\sqrt[k]{X}; \quad a, k \in \mathbb{R} \setminus \{0\}; \quad x > 0.$	$= \frac{k}{\lvert a \rvert} \left(\frac{y}{a}\right)^{k-1} f_X\left(\left[\frac{y}{a}\right]^k\right)$	$= \begin{cases} F_X\left(\left[\frac{y}{a}\right]^k\right) & \text{for } a > 0, \\ 1 - F_X\left(\left[\frac{y}{a}\right]^k\right) & \text{for } a < 0. \end{cases}$
$Y = a/X; \quad a \in \mathbb{R} \setminus \{0\}; \quad x > 0.$	$= \frac{\lvert a \rvert}{y^2} f_X\left(\frac{a}{y}\right)$	$= \begin{cases} F_X\left(\frac{a}{y}\right) & \text{for } a > 0, \\ 1 - F_X\left(\frac{a}{y}\right) & \text{for } a < 0. \end{cases}$

Please see the above Table. *The linear transformation*.

For more detailed result: see Rinne [481], p. 218-219.

4.1.2 Linear transformations of random variables

All distributions have location (L) and Scale (S) parameters along with any other parameters needed. The distributions are given in standard forms where $L = 0$ and $S = 1$. The nonstandard forms can be obtained for the various functions using the following transformations:

Table 2: The linear transformation

Function	Transformation
random variates	$\text{rnd}_X(L, S) = L + S \cdot \text{rnd}X(0, 1)$
cumulative distribution function	$\text{cdf}_X(x; L, S) = \text{cdf}_X\left(\frac{x-L}{S}; 0, 1\right)$
probability density function	$\text{pdf}_X(x; L, S) = \frac{1}{S} \cdot \text{pdf}_X\left(\frac{x-L}{S}; 0, 1\right)$
quantile function	$\text{qtf}_X(q; L, S) = L + S \cdot \text{qtf}_X(q; 0, 1)$
probability sparsity function	$\text{psf}_X(q; L, S) = S \cdot \text{psf}_X(q; 0, 1)$
hazard function	$\text{hf}_X(x; L, S) = \frac{1}{S} \cdot \text{hf}_X\left(\frac{x-L}{S}; 0, 1\right)$
cumulative hazard function	$\text{chf}_X(x; L, S) = \text{chf}_X\left(\frac{x-L}{S}; 0, 1\right)$
survival function	$\text{sf}_X(x; L, S) = \text{sf}_X\left(\frac{x-L}{S}; 0, 1\right)$
inverse survival function	$\text{isf}_X(p; L, S) = L + S \cdot \text{isf}_X(p; 0, 1)$
moment generating function	$M_X(t; L, S) = e^{t \cdot L} \cdot M_X(t \cdot S; 0, 1)$
characteristic function	$C_X(t; L, S) = e^{it \cdot L} \cdot C_X(t \cdot S; 0, 1)$
cumulant generating function	$K_X(t; L, S) = t \cdot L + K_X(t \cdot S; 0, 1)$
differential entropy	$\text{h}_X(L, S) = \text{h}_X(0, 1) + \log(S)$
mean	$\mu_X(1; L, S) = L + S \cdot \mu_X(1; 0, 1)$
central moments	$\mu_X(r; L, S) = S^r \cdot \mu_X(r; 0, 1); r > 1$
cumulants	$\kappa_X(r; L, S) = S^r \cdot \kappa_X(r; 0, 1); r > 1$

Please see the above Table. *The linear transformation*.

For more detailed result: see Rinne [481], p. 218-219.

Examples

- Standard normal distribution
- Ch-squared distribution with different scales

4.1.3 Random variables having mixture distributions

A random variable follows a mixture distribution if its cumulative distribution function (and the probability density function if it exists) can be expressed as a convex combination (i.e. a weighted sum, with non-negative weights w_i that sum to 1) of other distribution functions and density functions. The individual distributions that are combined to form the mixture distribution are called the mixture components, and the probabilities (or weights) associated with each component are called the mixture weights w_i. See also Wikipedia [1162].

Table 3: The mixture distribution

Function	Transformation
random variates	see text below
cumulative distribution function	$\text{cdf}_Z(x) = \sum_{i=1}^{k} w_i \cdot \text{cdf}_{X_i}(x)$
probability density function	$\text{pdf}_Z(x) = \sum_{i=1}^{k} w_i \cdot \text{pdf}_{X_i}(x)$
probability mass function	$\text{pmf}_Z(x) = \sum_{i=1}^{k} w_i \cdot \text{pmf}_{X_i}(x)$
survival function	$\text{sf}_Z(x) = \sum_{i=1}^{k} w_i \cdot \text{sf}_{X_i}(x)$
moment generating function	$M_Z(t) = \sum_{i=1}^{k} w_i \cdot M_{X_i}(t)$
characteristic function	$C_Z(t) = \sum_{i=1}^{k} w_i \cdot C_{X_i}(t)$
raw moments	$\mu'_Z(r) = \sum_{i=1}^{k} w_i \cdot \mu'_{X_i}(x)$

Please see the above Table. *The mixture distribution*.

The cumulants and the central moments can be calculated from the raw moments.

The cumulant generating function can be calculated from the moment generating function.

Examples

- Skellam: poisson with same rate back to back
- Laplace: exponential with same rate back to back
- Asymmetric Laplace: exponential with different rates back to back
- Hyperexponential distribution

4.1.4 Linear combinations of independent random variables

Suppose Z is the sum of n independent random variables $X_1, \ldots, X_n$ each with probability mass functions $f_{X_i}(x)$. Then $Z = \sum_{i=1}^{n} X_i$ is distributed as the convolution of the distributions of the X_i.

See also: Wikipedia [1163].

In cases where there are no known expressions in terms of other, readily computed distributions, the distribution of Z can be calculated using the characteristic functions of the X_i, as shown in the table below.

Table 4: The sums of random variables

Function	Transformation
random variates	$\text{rnd}_Z() = \sum_{i=1}^{k} a_i \cdot \text{rnd}_{X_i}()$
moment generating function	$M_Z(t) = \prod_{i=1}^{k} M_{X_i}(a_i \cdot t)$
characteristic function	$C_Z(t) = \prod_{i=1}^{k} C_{X_i}(a_i \cdot t)$
cumulant generating function	$K_Z(t) = \sum_{i=1}^{k} K_{X_i}(a_i \cdot t)$
cumulants	$\kappa_Z(r) = \sum_{i=1}^{k} a_i^r \cdot \kappa_{X_i}(r)$

Please see the above Table. *The sums of random variables*.

The raw moments and central moments are calculated from the cumulants.

The pmf, pdf and cdf are calculated by methods 1-3.

The qtf is started via the cumulants (Cornish-Fisher), followed by Newton iterations.

The pmf-vector is calculated via discrete convolution.

4.1.5 The log-transform of continuous random variables

A random variable X has a log-transform Y (which also is a random variable), if $\text{cdf}_X(x) = \text{cdf}_Y(\log(x))$, in other words if $\log(X) \sim Y$ (where $\sim$ means "is distributed as"). The transformation is only useful if the domain of X is (a, b) with $0 \leq a < b \leq \infty$ (otherwise the domain of Y would be extended into the complex plane). It is only implemented for continuous distributions.

The pdf, cdf, sf, qtf and isf of X and Y can be expressed in terms of each other, as shown below, together with the remarkable fact that the characteristic function of Y can be expressed in terms of the raw moments of X (this assumes that the raw moments of X are available in a form which allows to replace the discrete index variable r with the continuous complex variable it).

Table 5: The logarithmic transformation of a variable

Function	Transformation
random variates	$\text{rnd}_Y() = \log(\text{rnd}_X())$
	$\text{rnd}_X() = \exp(\text{rnd}_Y())$
probability density function	$\text{pdf}_Y(t) = \text{pdf}_X(\exp(t)) \cdot \exp(t)$
	$\text{pdf}_X(u) = \text{pdf}_Y(\log(u)) \cdot \frac{1}{u}$
cumulative distribution function	$\text{cdf}_Y(t) = \text{cdf}_X(\exp(t))$
	$\text{cdf}_X(u) = \text{cdf}_Y(\log(u))$
survival function	$\text{sf}_Y(t) = \text{sf}_X(\exp(t))$
	$\text{cdf}_X(u) = \text{cdf}_Y(\log(u))$
quantile function	$\text{qtf}_Y(q) = \exp(\text{qtf}_X)$
	$\text{qtf}_X(q) = \log(\text{qtf}_Y)$
inverse survival function	$\text{isf}_Y(q) = \exp(\text{isf}_X)$
	$\text{isf}_X(q) = \log(\text{isf}_Y)$
characteristic function of Y and raw moments of X	$C_Y(t) = \mu'_X(it)$

Please see the above Table. *The logarithmic transformation of a variable*.

One of the major features of the log-transform is its ability to express the distribution of the product of variables X_i as the sum of their log-transforms Y_i.

Examples

- Lognormal distribution

X: Lognormal

Y: Standard normal

- Beta distribution

4.2 Base class for univariate distributions

class rv_base(*rv_base*)

This is the base class, from which `rv_continuous` and `rv_discrete` inherit. There are no parameters and the support interval is $(-\infty, \infty)$.

The constructor has the following form:

```
class rv_continuous(rv_base):
    __a = -mp.inf
    __b = +mp.inf

    def __init__(self, df):
        pass
```

4.2.1 Boost: Cumulative distribution function

rv_base.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X:

See also Wikipedia [1125].

There are various ways to calculate a cdf. Ideally, it is available in closed from and can be calculated directly, or there is are dedicated functions to calculate it. If this is not the case, then one of the options given below can be used. There is no method which is always best, and the choice depends not only on the function, but also on the values of the argument and the parameters.

rv_base.**set_cdf_method**(*cdf_method*)

Sets the method to be used for the calculation of the cdf. `cdf_method` can take the following values:

1. "direct": this is the default if a closed form of the cdf exists, otherwise returns `not implemented`.
2. "from_pdf": only for continuous functions for which the pdf is available in closed form, otherwise returns `not implemented`.
3. "from_pmf": only for discrete functions, for which the pmf vector is available, otherwise returns `not implemented`.
4. "from_charfunc": only for functions for which the characteristic is available in closed form, otherwise returns `not implemented`.
5. "from_edgeworth": only if at least the first 2 cumulants exist, otherwise returns `not implemented`.
6. "from_lug_rice": only if the cumulant generating function exists, otherwise returns `not implemented`.

There may be additional options for any particular function, which are documented in the decription of the function.

4.2.2 Boost: Survival function

rv_base.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X.

See also Wikipedia [1144].

$$\mathrm{sf}_X(x) = 1 - \mathrm{cdf}_X(x) = \int_x^\infty \mathrm{pdf}_X(x)\mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

4.2.3 Hazard function

`rv_continuous.`**`hazard`**`(`x`)`

Returns $\text{hazard}_X(x)$, the hazard function of a random variable X, defined as the ratio of the probability density function to the survival function.

See also Wikipedia [1129], BoostMath [46].

$$\text{hazard}_X(x) = \frac{\text{pdf}_X(x)}{\text{sf}_X(x)} = \frac{\text{pdf}_X(x)}{1 - \text{cdf}_X(x)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

4.2.4 Cumulative Hazard Function

`rv_continuous.`**`chf`**`(`x`)`

Returns $\text{chf}_X(x)$, the cumulative function of a random variable X, defined as the ratio of the probability density function to the survival function.

See also Wikipedia [1129], BoostMath [39].

$$\text{chf}_X(x) == \int_{-\infty}^{x} \text{hazard}_X(x)\text{d}t = -\log(1 - \text{cdf}_X(x)).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

4.2.5 Boost: Quantile function

`rv_base.`**`qtf`**`(`x`)`

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X.

$$\text{qtf}_X(q) = \text{cdf}_X^{-1}(q).$$

See also Wikipedia [1139].

There are various ways to calculate the quantile function. Ideally, it is available in closed from and can be calculated directly, or there is are dedicated functions to calculate it. If this is not the case, then one of the options given below can be used. There is no method which is always best, and the choice depends not only on the function, but also on the values of the argument and the parameters.

`rv_base.`**`set_qtf_method`**`(`*qtf_method*`)`

Sets the method to be used for the calculation of the cdf. `qtf_method` can take the following values:

1. "direct": this is the default if a closed form of the quantile function exists.
2. "from_cdf": this is the default if a closed form of the qtf does not exist.
3. "from_cornish_fisher": only if at least the first 2 cumulants exist, otherwise returns `not implemented`.
4. "from_jensen": only if the cumulant generating function exists, otherwise returns `not implemented`.

There may be additional options for any particular function, which are documented in the decription of the function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

4.2.6 Boost: Inverse survival function

`rv_base.isf(`x`)`

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X.

See also Wikipedia [1139]

$$\mathrm{isf}_X(q) = \mathrm{qtf}_X(1-q) = \mathrm{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

4.2.7 Boost: Mode

`rv_base.mode()`

Returns the mode of the function.

See also Wikipedia [1134]

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

4.2.8 Boost: Expected value (mean)

`rv_base.mean()`

Returns the expected value (mean) of the function.

See also Wikipedia [1127].

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

4.2.9 Boost: Median

`rv_base.median()`

Returns the median of the function.

See also Wikipedia [1133]

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

4.2.10 Boost: Variance

`rv_base.variance()`

Returns the variance of the function.

See also Wikipedia [1146].

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

4.2.11 Boost: Standard deviation

`rv_base.stdev()`

Returns the Standard deviation of the function.

See also Wikipedia [1142].

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

4.2.12 Boost: Skewness

`rv_base.skewness()`

Returns the skewness of the function.

See also Wikipedia [1141].

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

4.2.13 Boost: Kurtosis

`rv_base.kurtosis()`

Returns the 'proper' kurtosis (normalized fourth moment) of the distribution dist.kurtosis μ_4/μ_2^2, where μ_i is the i'th central moment of the distribution, and in particular μ_2 is the variance of the distribution.

See also Wikipedia [1132].

The kurtosis is a measure of the "peakedness" of a distribution.

Note that the literature definition of kurtosis is confusing. The definition used here is that used by for example Wolfram MathWorld (that includes a table of formulae for kurtosis excess for various distributions) but NOT the definition of kurtosis used by Wikipedia which treats "kurtosis" and "kurtosis excess" as the same quantity.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

4.2.14 Boost: Kurtosis excess

`rv_base.`**`excess_kurtosis`**`()`

Returns the kurtosis excess of the distribution dist. kurtosis excess = kurtosis - 3.

See also Wikipedia [1126].

The kurtosis excess is a measure of the "peakedness" of a distribution, and is more widely used than the "kurtosis proper". It is defined so that the kurtosis excess of a normal distribution is zero.

This function may return a domain_error if the distribution does not have a defined kurtosis excess.

Kurtosis excess can have a value from -2 to + infinity.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

4.2.15 Boost: Support, lower endpoint

`Dist.`**`support_lower_endpoint`**`()`

Returns the lower endpoint of the support of the function.

See also Wikipedia [1143].

See also https://en.wikipedia.org/wiki/Interval_(mathematics)

The distribution is said to be 'supported' over a range that is "the smallest closed set whose complement has probability zero". Non-mathematicians might say it means the 'interesting' smallest range of random variate x that has the cdf going from zero to unity. Outside are uninteresting zones where the pdf is zero, and the cdf zero or unity.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

4.2.16 Boost: Support, upper endpoint

`Dist.`**`support_upper_endpoint`**`()`

Returns the upper endpoint of the support of the function.

See also Wikipedia [1143].

See also https://en.wikipedia.org/wiki/Interval_(mathematics)

The distribution is said to be 'supported' over a range that is "the smallest closed set whose complement has probability zero". Non-mathematicians might say it means the 'interesting' smallest range of random variate x that has the cdf going from zero to unity. Outside are uninteresting zones where the pdf is zero, and the cdf zero or unity.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

4.2.17 Boost: Range, lower endpoint

`Dist.range_lower_endpoint()`

Returns the lower endpoint of the valid range of the random variable.

See also Wikipedia [1143].

See also https://en.wikipedia.org/wiki/Interval_(mathematics)

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

4.2.18 Boost: Range, upper endpoint

`Dist.range_upper_endpoint()`

Returns the upper endpoint of the valid range of the random variable.

See also Wikipedia [1143].

See also https://en.wikipedia.org/wiki/Interval_(mathematics)

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

4.2.19 Characteristic function

`rv_base.c_x(t)`

Returns $C_X(t)$, the characteristic function of a random variable X.

See also Wikipedia [1123], Wikipedia [1127].

For a scalar random variable X the characteristic function is defined as the expected value of e^{itX}, where i is the imaginary unit, and $t \in \mathbb{R}$ is the argument of the characteristic function:

$$C_X(t) = \mathrm{E}\left[e^{itX}\right] = \int_{-\infty}^{\infty} e^{itx} d\,\mathrm{cdf}_X(x) = \int_{-\infty}^{\infty} e^{itx} \mathrm{pdf}_X(x) \mathrm{d}x = \int_0^1 e^{it\ \mathrm{qtf}_X(p)} dp = M_X(it).$$

Here $\mathrm{cdf}_X(x)$ is the cumulative distribution function of X, and the integral is of the Riemann–Stieltjes kind. If a random variable X has a probability density function $\mathrm{pdf}_X(x)$, then the characteristic function is its Fourier transform with sign reversal in the complex exponential. $\mathrm{qtf}_X(p)$ is the quantile function of X, also known as the inverse cumulative distribution function of X or the quantile function of X. $M_X(t)$ is the moment generating function of X. Note that the characteristic function of a distribution always exists, even when the probability density function or moment-generating function do not.

There are various ways to calculate the characteristic function. Ideally, it is available in closed from and can be calculated directly, or there is are dedicated functions to calculate it. If this is not the case, then one of the options given below can be used. There is no method which is always best, and the choice depends not only on the function, but also on the values of the argument and the parameters.

rv_base.**set_cf_method**(*qtf_method*)

Sets the method to be used for the calculation of the cdf. `qtf_method` can take the following values:

1. "direct": this is the default if a closed form of the characteristic function exists.
2. "from_pdf": only if the pdf is available in closed form, otherwise returns `not implemented`.
3. "from_qtf": only if the qtf is available in closed form, otherwise returns `not implemented`.
4. "from_moments": only if the raw moments are available in closed form, otherwise returns `not implemented`.

There may be additional options for any particular function, which are documented in the decription of the function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

4.2.20 Moment generating function

rv_base.**m_x**(x)

Returns $M_X(t)$, the moment generating function of a random variable X.

See also Wikipedia [1136].

There are various ways to calculate the moment generating function. Ideally, it is available in closed from and can be calculated directly, or there is are dedicated functions to calculate it. If this is not the case, then one of the options given below can be used. There is no method which is always best, and the choice depends not only on the function, but also on the values of the argument and the parameters.

rv_base.**set_mgf_method**(*mgf_method*)

Sets the method to be used for the calculation of the mgf. `mgf_method` can take the following values:

1. "direct": this is the default if a closed form of the moment generating function exists.
2. "from_charfunc": only if the characteristic is available in closed form, otherwise returns `not implemented`.
3. "from_cgf": only if the moment generating function is available in closed form, otherwise returns `not implemented`.
4. "from_pgf": only for discrete distributions and only if the probability generating function is available in closed form, otherwise returns `not implemented`.
5. "from_moments": only if the raw moments are available in closed form, otherwise returns `not implemented`.

There may be additional options for any particular function, which are documented in the decription of the function.

Related to the moment-generating function are a number of other transforms that are common in probability theory:

4.2.21 Cumulant generating function

rv_base.**k_x**(x)

Returns $K_X(t)$, the cumulant generating function of a random variable X.

See also Wikipedia [1124].

There are various ways to calculate the cumulant generating function. Ideally, it is available in closed from and can be calculated directly, or there is are dedicated functions to calculate it. If this is not the case, then one of the options given below can be used. There is no method which is always best, and the choice depends not only on the function, but also on the values of the argument and the parameters.

`rv_base.set_cgf_method(cgf_method)`

Sets the method to be used for the calculation of the cgf. `cgf_method` can take the following values:

1. "direct": this is the default if a closed form of the moment generating function exists.
2. "from_charfunc": only if the characteristic function is available in closed form, otherwise returns `not implemented`.
3. "from_mgf": only if the moment generating function is available in closed form, otherwise returns `not implemented`.
4. "from_pgf": only for discrete distributions and only if the probability generating function is available in closed form, otherwise returns `not implemented`.
5. "from_cumulants": only if the cumulants are available in closed form, otherwise returns `not implemented`.

There may be additional options for any particular function, which are documented in the decription of the function.

4.2.22 Raw Moments

`rv_base.raw_moments(k)`

Returns the first j raw moments, $\mu_j, j = 1 \dots k$, of a random variable X.

See also Wikipedia [1135]

There are various ways to calculate the raw moments. Ideally, they are available in closed from and can be calculated directly, or there is are dedicated functions to calculate them. If this is not the case, then one of the options given below can be used. There is no method which is always best.

`rv_base.set_moments_method(moments_method)`

Sets the method to be used for the calculation of the raw moments. `moments_method` can take the following values:

1. "direct": this is the default if a closed form of the cdf exists, otherwise returns `not implemented`.
2. "from_pdf": only for continuous functions for which the pdf is available in closed form, otherwise returns `not implemented`.
3. "from_pmf": only for discrete functions, for which the pmf vector is available, otherwise returns `not implemented`.
4. "from_cumulants": only if the cumulants are available in closed form, otherwise returns `not implemented`.
5. "from_mgf": only for functions for which the moment generating function is available in closed form, otherwise returns `not implemented`.
6. "from_charfunc": only for functions for which the characteristic function is available in closed form, otherwise returns `not implemented`.
7. "from_pgf": only for discrete distributions and only for functions for which the moment generating function is available in closed form, otherwise returns `not implemented`.

There may be additional options for any particular function, which are documented in the decription of the function.

4.2.23 Central Moments

`rv_base.central_moments(k)`

Returns the first j central moments, $\mu_j, j = 1 \dots k$, of a random variable X.

See also Wikipedia [1124]

There are various ways to calculate the central moments. Ideally, they are available in closed from and can be calculated directly, or there is are dedicated functions to calculate them. If this is not the case, then one of the options given below can be used. There is no method which is always best.

rv_base.**set_central_moments_method**(*central_moments_method*)

Sets the method to be used for the calculation of the central_moments_method. `central_moments_method` can take the following values:

1. "direct": this is the default if a closed form of the cdf exists, otherwise returns `not implemented`.
2. "from_raw_moments": only if the raw moments are available in closed form, otherwise returns `not implemented`.
3. "from_cumulants": only if the cumulants are available in closed form, otherwise returns `not implemented`.
4. "from_pdf": calculates the raw moments from the pdf, the converts the raw moments to the central moments.

There may be additional options for any particular function, which are documented in the decription of the function.

4.2.24 Cumulants

rv_base.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \dots k$, of a random variable X.

See also Wikipedia [1124]

There are various ways to calculate the cumulants. Ideally, they are available in closed from and can be calculated directly, or there is are dedicated functions to calculate them. If this is not the case, then one of the options given below can be used. There is no method which is always best.

rv_base.**set_cumulants_method**(*cumulants_method*)

Sets the method to be used for the calculation of the cumulants. `cumulants_method` can take the following values:

1. "direct": this is the default if a closed form of the cdf exists, otherwise returns `not implemented`.
2. "from_moments": only if the moments are available in closed form, otherwise returns `not implemented`.
3. "from_cgf": only for functions for which the moment generating function is available in closed form, otherwise returns `not implemented`.

There may be additional options for any particular function, which are documented in the decription of the function.

4.3 Base class for continuous univariate distributions

class rv_continuous(*rv_base*)

The base continuous probability distribution class, which inherits from `rv_base`. There are no parameters and the support interval is $(-\infty, \infty)$.

The constructor has the following form:

```
class rv_continuous(rv_base):
    __a = -mp.inf
    __b = +mp.inf

    def __init__(self, df):
        pass
```

4.3.1 Probability density function

`rv_continuous.`**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X:

See also Wikipedia [1137].

There are various ways to calculate a pdf. Ideally, it is available in closed from and can be calculated directly, or there is are dedicated functions to calculate it. If this is not the case, then one of the options given below can be used. There is no method which is always best, and the choice depends not only on the function, but also on the values of the argument and the parameters.

`rv_base.`**set_pdf_method**(*pdf_method*)

Sets the method to be used for the calculation of the pdf. `pdf_method` can take the following values:

1. "direct": this is the default if a closed form of the cdf exists, otherwise returns `not implemented`.
2. "from_cdf": only for continuous functions for which the pdf is available in closed form, otherwise returns `not implemented`.
3. "from_charfunc": only for functions for which the characteristic is available in closed form, otherwise returns `not implemented`.
4. "from_edgeworth": only if at least the first 2 cumulants exist, otherwise returns `not implemented`.
5. "from_lug_rice": only if the cumulant generating function exists, otherwise returns `not implemented`.

There may be additional options for any particular function, which are documented in the decription of the function.

4.3.2 Probability sparsity function

`rv_continuous.`**psf**(x)

Returns $\text{psf}_X(x)$, the probability sparsity function (psf), which is the derivative of the quantile function (qtf).

See also Wikipedia [1139], Wikipedia [1131].

The probability sparsity function can be calculated using the probability density function (pdf) and the qtf:

$$\text{psf}_X(q) = \frac{\mathrm{d}}{\mathrm{d}q}\text{qtf}_X(q) = \frac{1}{\text{pdf}_X(\text{qtf}_X(q))}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

4.3.3 Differerential entropy

rv_continuous.**entropy**(x)

Returns entropy$_X(x)$, the differential entropy of a random variable X.

See also Wikipedia [1151]

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561456135 6E+00
```

4.3.4 Negative loglikelihood function

See also Wikipedia [1156]

rv_continuous.**nnlf**(x)

Returns nnlf$_X(x)$, the negative loglikelihood function of a random variable X:

$$\text{nnlf}_X(x) = -\sum(\log \text{pdf}_X(x, \theta), axis = 0),$$

where theta are the parameters (including loc and scale).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561456135 6E+00
```

4.3.5 Logarithm of the probability density function

rv_continuous.**logpdf**(x)

Returns logpdf$_X(x)$, the logarithm of the probability density function (pdf) of a random variable X.

See also Wikipedia [1137]

$$\text{logpdf}_X(x) = \log(\text{pdf}_X(x))$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561456135 6E+00
```

4.4 Base class for discrete univariate distributions

class rv_discrete(*rv_base*)

The base discrete probability distribution class, which inherits from `rv_base`. There are no parameters and the support interval is $(-\infty, \infty)$.

The constructor has the following form:

```
class rv_continuous(rv_base):
    __a = -mp.inf
    __b = +mp.inf

    def __init__(self, df):
        pass
```

4.4.1 Probability mass function

rv_discrete.**pmf**(x)

Returns $\text{pmf}_X(x)$, the probability mass function (pmf) of a random variable X.

See also Wikipedia [1171].

There are various ways to calculate a pmf. Ideally, it is available in closed from and can be calculated directly, or there is are dedicated functions to calculate it. If this is not the case, then one of the options given below can be used. There is no method which is always best, and the choice depends not only on the function, but also on the values of the argument and the parameters.

rv_base.**set_pmf_method**(*pmf_method*)

Sets the method to be used for the calculation of the pmf. `pmf_method` can take the following values:

1. "direct": this is the default if a closed form of the cdf exists, otherwise returns `not implemented`.
2. "from_pmf_vector": only for discrete functions for which the pmf vector is available in polynomial time, otherwise returns `not implemented`.
3. "from_charfunc": only for functions for which the characteristic is available in closed form, otherwise returns `not implemented`.
4. "from_edgeworth": only if at least the first 2 cumulants exist, otherwise returns `not implemented`.
5. "from_lug_rice": only if the cumulant generating function exists, otherwise returns `not implemented`.

There may be additional options for any particular function, which are documented in the decription of the function.

4.4.2 Probability generating function

See also Wikipedia [1172].

rv_discrete.**pgf**(x)

Returns $\text{pgf}_X(x)$, the probability generating function (pgf) of a discrete random variable X.

See also Wikipedia [1172].

It is a power series representation (the generating function) of the probability mass function of the random variable.

If X is a discrete random variable taking values in the non-negative integers $\{0, 1, ...\}$, then the probability generating function of X is defined as

$$G(z) = \mathrm{E}(z^X) = \sum_{x=0}^{\infty} p(x) z^x,$$

where p is the probability mass function of X. Note that the subscripted notations G_X and p_X are often used to emphasize that these pertain to a particular random variable X, and to its distribution. The power series converges absolutely at least for all complex numbers z with $|z| \leq 1$; in many examples the radius of convergence is larger.

The probability-generating function is related to the moment-generating function by

$$G_X(e^t) = M_X(t); \quad G(t) = M_X(\log(t)).$$

There are various ways to calculate a pgf. Ideally, it is available in closed from and can be calculated directly, or there is are dedicated functions to calculate it. If this is not the case, then one of the options given below can be used. There is no method which is always best, and the choice depends not only on the function, but also on the values of the argument and the parameters.

`rv_base.`**`set_pgf_method`**(*pgf_method*)

Sets the method to be used for the calculation of the pgf. `pgf_method` can take the following values:

1. "direct": this is the default if a closed form of the cdf exists, otherwise returns `not implemented`.
2. "from_pmf_vector": only for discrete functions for which the pmf vector is available in polynomial time, otherwise returns `not implemented`.
3. "from_charfunc": only for functions for which the characteristic function is available in closed form, otherwise returns `not implemented`.
4. "from_mgf": only for functions for which the moment generating function is available in closed form, otherwise returns `not implemented`.
5. "from_mgf": only for functions for which the moment generating function is available in closed form, otherwise returns `not implemented`.

There may be additional options for any particular function, which are documented in the decription of the function.

4.4.3 Vector containing all values of the pmf

`rv_discrete.`**`pmfvec`**(x)

Returns a vector containing all values of the pmf. This is useful is such a vector is cheap to compute, and further operations (like convolutions) are required.

See also Wikipedia [1171].

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145614356E+00
```

4.4.4 Entropy

`rv_discrete.`**`entropy`**(x)

Returns entropy$_X(x)$, the entropy of a random variable X.

See also Wikipedia [1151].

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145614356E+00
```

4.4.5 Logarithm of the probability mass function

rv_discrete.**logpmf**(x)

Returns $\text{logpmf}_X(x)$, the logarithm of the probability mass function (pmf) of a random variable X.

See also Wikipedia [1171].

$$\text{logpmf}_X(x) = \log(\text{pmf}_X(x))$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

4.5 Closed form distributions, based on elementary functions

4.5.1 Boost: Arcsine Distribution

The following functions return the pdf, cdf, qtf or boost class of the arcsine distribution with endpoints $a \in \mathbb{R}$ and $b \in \mathbb{R}$, and the support interval (a, b).

See also Wikipedia [1147], BoostMath [50].

`math53.`**`arcsine_pdf`**(a, b, x)

Returns $\text{pdf}(x)$, the value of the probability density function (*Pdf*) of the arcsine distribution:

$$\text{pdf}(x) = \frac{1}{\pi\sqrt{(x-a)(b-x)}}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("ArcsinePdf(x, a, b): ", ArcsinePdf(x, a, b))
>>> print ("dist_arcsine(a, b).pdf(x): ", dist_arcsine(a, b).pdf(x))
6.356352346256452561561561561456 1356E+00
```

`math53.`**`arcsine_cdf`**(a, b, x)

Returns $\text{cdf}(x)$, the value of the cumulative distribution function (*Cdf*) of the arcsine distribution:

$$\text{cdf}(x) = \frac{2}{\pi}\arcsin\left(\sqrt{\frac{x-a}{b-a}}\right)$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("ArcsineCdf(x, a, b): ", ArcsineCdf(x, a, b))
>>> print ("dist_arcsine(a, b).cdf(x): ", dist_arcsine(a, b).cdf(x))
6.356352346256452561561561561456 1356E+00
```

`math53.`**`arcsine_qtf`**(a, b, q)

where `Ctx` is `Math53` or `CtxBoost`.

Returns $\text{qtf}(q)$, the value of the quantile function (*Qtf*) of the arcsine distribution:

$$\text{qtf}(q) = a + (b-a)\left(\sin\left(\tfrac{1}{2}\pi \cdot q\right)\right)^2$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("ArcsineQtf(q, a, b): ", ArcsineQtf(q, a, b))
>>> print ("dist_arcsine(a, b).qtf(q): ", dist_arcsine(a, b).qtf(q))
6.356352346256452561561561561456 1356E+00
```

class ctx.**dist_arcsine**(a, b)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The arcsine distribution is a continuous probability distribution with endpoints $a \in \mathbb{R}$ and $b \in \mathbb{R}$, $a < b$, and the support interval (a, b).

See also Wikipedia [1147], MathWorld [243], BoostMath [50], Witkovský [1464].

dist_arcsine.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an arcsine distribution:

$$\mathrm{pdf}_X(x) = \frac{1}{\pi\sqrt{(x-a)(b-x)}}.$$

An example:

```
>>> from xlcalcnet import mpm
>>> mpm.dps = 30; a = '0'; b = '1'; x = '0.25'
>>> print ("pdf: ", mpm.dist_arcsine(a, b).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_arcsine.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an arcsine distribution:

$$\mathrm{cdf}_X(x) = \frac{2}{\pi}\arcsin\left(\sqrt{\frac{x-a}{b-a}}\right).$$

An example:

```
>>> from xlcalcnet import mpm
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", mpm.arcsine(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_arcsine.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following an arcsine distribution:

$$\mathrm{sf}_X(x) = \frac{2}{\pi}\arccos\left(\sqrt{\frac{x-a}{b-a}}\right).$$

An example:

```
>>> from xlcalcnet import mpm
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", mpm.arcsine(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_arcsine.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following an arcsine distribution:

$$\mathrm{qtf}_X(q) = a + (b-a)\left(\sin\left(\tfrac{1}{2}\pi \cdot q\right)\right)^2$$

```
>>> from xlcalcnet import mpm
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", mpm.arcsine(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561456 1356E+00
```

dist_arcsine.**isf**(*q*)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following an arcsine distribution:

$$\text{isf}_X(q) = a + (b-a)\left(\cos\left(\tfrac{1}{2}\pi \cdot q\right)\right)^2$$

```
>>> from xlcalcnet import mpm
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", mpm.arcsine(mu, sigma).isf(q))
6.356352346256452561561561561456 1356E+00
```

dist_arcsine.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following an arcsine distribution:

$$C_X(t) = {}_1F_1\left(\frac{1}{2}; 1; it\right).$$

```
>>> from xlcalcnet import mpm
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mpm.arcsine(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

dist_arcsine.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following an arcsine distribution:

$$M_X(t) = {}_1F_1\left(\frac{1}{2}; 1; t\right).$$

```
>>> from xlcalcnet import mpm
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", mpm.arcsine(mu, sigma).m_x(t))
6.356352346256452561561561561456 1356E+00
```

dist_arcsine.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an arcsine distribution:

$$K_X(t) = \log\left[{}_1F_1\left(\frac{1}{2}; 1; t\right)\right].$$

```
>>> from xlcalcnet import mpm
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("k_x: ", mpm.arcsine(mu, sigma).k_x(t, k))
6.356352346256452561561561561456 1356E+00
```

dist_arcsine.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an arcsine distribution:

$$\mu'_X(r) = \prod_{j=0}^{n-1} \frac{2j+1}{2j+2}.$$

```
>>> from xlcalcnet import mpm
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("moments: ", mpm.arcsine(mu, sigma).moments(k))
6.356352346256452561561561456135 6E+00
```

dist_arcsine.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an arcsine distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import mpm
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("cumulants: ", mpm.arcsine(mu, sigma).cumulants(k))
6.356352346256452561561561456135 6E+00
```

4.5.2 Boost: Cauchy distribution

The following functions return the pdf, cdf, qtf or boost class of the Cauchy distribution with parameters $a \in \mathbb{R}$ (location), $b > 0$ (scale), and the support interval $(-\infty, +\infty)$.

See also Wikipedia [1149], MathWorld [819], BoostMath [52], Ehrhardt [297] (3.9.4).

`math53.cauchy_pdf`(a, b, x)

Returns pdf(x), the value of the probability density function (*Pdf*) of the Cauchy distribution:

$$\text{pdf}(x) = \frac{1}{\pi b(1 + ((x-a)/b)^2)}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("CauchyPdf(x, a, b): ", CauchyPdf(x, a, b))
>>> print ("dist_cauchy(a, b).pdf(x): ", dist_cauchy(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.cauchy_cdf`(a, b, x)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the Cauchy distribution:

$$\text{cdf}(x) = \frac{1}{2} + \frac{1}{\pi}\arctan\left(\frac{x-a}{b}\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("CauchyCdf(x, a, b): ", CauchyCdf(x, a, b))
>>> print ("dist_cauchy(a, b).cdf(x): ", dist_cauchy(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.cauchy_qtf`(a, b, q)

Returns qtf(q), the value of the quantile function (*Qtf*) of the Cauchy distribution:

$$\text{qtf}(q) = \begin{cases} a - b/\tan(\pi q), & q < 0.5, \\ a, & q = 0.5, \\ a - b/\tan(\pi(1-q)) & q > 0.5. \end{cases}$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("CauchyQtf(q, a, b): ", CauchyQtf(q, a, b))
>>> print ("dist_cauchy(a, b).qtf(q): ", dist_cauchy(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class `ctx.dist_cauchy`(a, b)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The Cauchy distribution is a continuous probability distribution with parameters $a \in \mathbb{R}$ (location), $b > 0$ (scale), and the support interval $(-\infty, +\infty)$. See also Wikipedia [1149], MathWorld [819], BoostMath [52], R (Statistical System) [521].

dist_cauchy.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a Cauchy distribution:

$$\text{pdf}_X(x) = \frac{1}{\pi(1 + ((x-a)/b)^2)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", cauchy(mu, sigma).pdf(x))
6.356352346256452561561561456135 6E-20
```

dist_cauchy.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Cauchy distribution:

$$\text{cdf}_X(x) = \frac{1}{2} + \frac{1}{\pi}\arctan\left(\frac{x-a}{b}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", cauchy(mu, sigma).pdf(x))
6.356352346256452561561561456135 6E-20
```

dist_cauchy.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following a Cauchy distribution:

$$\text{sf}_X(x) = 1 - \text{cdf}_X(x) = \frac{1}{2} - \frac{1}{\pi}\arctan\left(\frac{x-a}{b}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", cauchy(mu, sigma).pdf(x))
sf: 6.356352346256452561561561456135 6E-20
```

dist_cauchy.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Cauchy distribution:

$$\text{qtf}_X(q) = \begin{cases} a - b/\tan(\pi q), & q < 0.5, \\ a, & q = 0.5, \\ a - b/\tan(\pi(1-q)) & q > 0.5. \end{cases}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", cauchy(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561456135 6E+00
```

dist_cauchy.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Cauchy distribution:

$$\text{isf}_X(q) = \begin{cases} a + b/\tan(\pi q), & q < 0.5, \\ a, & q = 0.5, \\ a + b/\tan(\pi(1-q)) & q > 0.5. \end{cases}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", cauchy(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_cauchy.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Cauchy distribution:

$$C_X(t) = \exp(a \cdot it - b|t|).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", cauchy(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_cauchy.**m_x**(t)

Returns NaN, since the moment generating function does not exist.

dist_cauchy.**k_x**(t, *k=0*)

Returns NaN, since the cumulant generating function does not exist.

dist_cauchy.**moments**(k)

Returns NaN, since moments do not exist.

dist_cauchy.**cumulants**(k)

Returns NaN, since cumulants do not exist.

4.5.3 Boost: Exponential distribution

The following functions return the pdf, cdf, qtf or boost class of the distribution with rate parameter $\lambda_1 > 0$ and the support interval $(0, +\infty)$.

See also Wikipedia [1152], MathWorld [821], BoostMath [54], Ehrhardt [297] (3.9.7).

`math53.`**`exponential_pdf`**(*lambda1*, *x*)

Returns pdf(x), the value of the probability density function (*Pdf*) of the exponential distribution:

$$\text{pdf}(x) = \lambda_1 \exp(-\lambda_1 x).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("ExponentialPdf(x, a, b): ", ExponentialPdf(x, a, b))
>>> print ("dist_exponential(a, b).pdf(x): ", dist_exponential(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`exponential_cdf`**(*lambda1*, *x*)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the exponential distribution:

$$\text{cdf}(x) = 1 - \exp(-\lambda_1 x) = -\text{expm1}(-\lambda_1 x).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("ExponentialCdf(x, a, b): ", ExponentialCdf(x, a, b))
>>> print ("dist_exponential(a, b).cdf(x): ", dist_exponential(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`exponential_qtf`**(*lambda1*, *q*)

Returns qtf(q), the value of the quantile function (*Qtf*) of the exponential distribution:

$$\text{qtf}(q) = -\text{log1p}(-q)/\lambda_1.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("ExponentialQtf(q, a, b): ", ExponentialQtf(q, a, b))
>>> print ("dist_exponential(a, b).qtf(q): ", dist_exponential(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

`class` `ctx.`**`dist_exponential`**(*lambda1*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The exponential distribution is a continuous probability distribution with rate parameter $\lambda_1 > 0$, and the support interval $[0, +\infty)$. See also Wikipedia [1152], MathWorld [821], BoostMath [54], Witkovský [1467], R (Statistical System) [523].

dist_exponential.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an exponential distribution:

$$\text{pdf}_X(x) = \lambda_1 \exp(-\lambda_1 x).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", exponential(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_exponential.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an exponential distribution:

$$\text{cdf}_X(x) = 1 - \exp(-\lambda_1 x) = -\text{expm1}(-\lambda_1 x).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", exponential(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_exponential.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following an exponential distribution:

$$\text{sf}_X(x) = \exp(-\lambda_1 x).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", exponential(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_exponential.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following an exponential distribution:

$$\text{qtf}_X(q) = -\text{log1p}(-q)/\lambda_1.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", exponential(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_exponential.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following an exponential distribution:

$$\text{isf}_X(q) = -\log(q)/\lambda_1.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", exponential(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_exponential.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following an exponential distribution:

$$C_X(t) = \frac{\lambda}{\lambda - it}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", exponential(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_exponential.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following an exponential distribution:

$$M_X(t) = \frac{\lambda}{\lambda - t}, \quad \text{for } t < \lambda.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", exponential(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_exponential.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an exponential distribution:

$$K_X(t) = \log\left(\frac{\lambda}{\lambda - t}\right), \quad \text{for } t < \lambda.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", exponential(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_exponential.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an exponential distribution. The rth moments only exists for $n_2 > 2r$.

$$\mu'_X(n) = \frac{n!}{\lambda^n}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", exponential(mu, sigma).moments(k))
6.356352346256452561561561456l356E+00
```

dist_exponential.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an exponential distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", exponential(mu, sigma).cumulants(k))
6.356352346256452561561561456l356E+00
```

4.5.4 Boost: Gumbel (Generalized Extreme Value distribution Type-I) distribution

The following functions return the pdf, cdf, qtf or boost class of the Gumbel distribution with parameters $a \in \mathbb{R}$ (location), $b > 0$ (scale), and the support interval $(-\infty, +\infty)$.

See also Wikipedia [1155], MathWorld [824], BoostMath [55], Ehrhardt [297] (3.9.8).

math53.**gumbel_pdf**(a, b, x)

Returns pdf(x), the value of the probability density function (*Pdf*) of the Gumbel distribution:

$$\text{pdf}(x) = \frac{e^{-(x-a)/b}}{b} e^{-e^{-(x-a)/b}}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("GumbelPdf(x, a, b): ", GumbelPdf(x, a, b))
>>> print ("dist_gumbel(a, b).pdf(x): ", dist_gumbel(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

math53.**gumbel_cdf**(a, b, x)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the Gumbel distribution:

$$\text{cdf}(x) = e^{-e^{-(x-a)/b}}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("GumbelCdf(x, a, b): ", GumbelCdf(x, a, b))
>>> print ("dist_gumbel(a, b).cdf(x): ", dist_gumbel(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

math53.**gumbel_qtf**(a, b, q)

Returns qtf(q), the value of the quantile function (*Qtf*) of the Gumbel distribution:

$$\text{qtf}(q) = a - b\log(-\log(q)).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("GumbelQtf(q, a, b): ", GumbelQtf(q, a, b))
>>> print ("dist_gumbel(a, b).qtf(q): ", dist_gumbel(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class ctx.**dist_gumbel**(a, b)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The Gumbel (or Extreme Value Type I)distribution is a continuous probability distribution with parameters $a \in \mathbb{R}$ (location), $b > 0$ (scale), and the support interval $(-\infty, +\infty)$.

See also Wikipedia [1155], MathWorld [824], BoostMath [55], Witkovský [1470].

Note: In MathWorld/Mathematica, the Gumbel (Maximum) distribution is called the ExtremeValueDistribution, and the Gumbel (Minimum) distribution is called the GumbelDistribution.

dist_gumbel.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Gumbel distribution:

$$\mathrm{pdf}_X(x) = \frac{e^{-(x-a)/b}}{b} e^{e^{-(x-a)/b}}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", gumbel(mu, sigma).pdf(x))
6.356352346256452561561561456135 6E-20
```

dist_gumbel.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Gumbel distribution:

$$\mathrm{cdf}_X(x) = e^{e^{-(x-a)/b}}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", gumbel(mu, sigma).pdf(x))
6.356352346256452561561561456135 6E-20
```

dist_gumbel.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following an Gumbel distribution:

$$\mathrm{sf}_X(x) = 1 - e^{e^{-(x-a)/b}} = -\mathrm{expm1}(-e^{-(x-a)/b}).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", gumbel(mu, sigma).pdf(x))
sf: 6.356352346256452561561561456135 6E-20
```

dist_gumbel.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following an Gumbel distribution:

$$\mathrm{qtf}_X(q) = a - b\log(-\log(q)).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", gumbel(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561456135 6E+00
```

dist_gumbel.**isf**(*q*)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following an Gumbel distribution:

$$\text{isf}_X(q) = a - b\log(-\text{log1p}(-q)).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", gumbel(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_gumbel.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following an Gumbel distribution:

$$C_X(t) = \Gamma(1 - ibt)e^{iat}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", gumbel(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_gumbel.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following an Gumbel distribution:

$$M_X(t) = \Gamma(1 - bt)e^{at}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", gumbel(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_gumbel.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an Gumbel distribution:

$$K_X(t) = at + \log(\Gamma(1 - bt)).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", gumbel(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_gumbel.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an Gumbel distribution. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", gumbel(mu, sigma).moments(k))
6.356352346256452561561561561456l356E+00
```

dist_gumbel.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an Gumbel distribution:

$$\kappa'_X(n) = (n-1)!\zeta(n).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", gumbel(mu, sigma).cumulants(k))
6.356352346256452561561561561456l356E+00
```

4.5.5 Boost: Hyperexponential Distribution

The following functions return pdf, cdf, qtf or boost class of the hyperexponential distribution with weights $w_j > 0$, rate parameters $\lambda_j > 0$, $j = 1 \ldots k$, and the support interval $(0, +\infty)$. The weights are interpreted as relative weights, to ensure that $\sum_{j=1}^{k} w_j = 1$.

See also Wikipedia [1180], MathWorld [249], BoostMath [77].

`math53.`**`hyperexponential_pdf`**(*lambdaj*, *wj*, *x*)

Returns pdf(x), the value of the probability density function (*Pdf*) of the hyperexponential distribution:

$$\text{pdf}(x) = \sum_{j=1}^{k} w_j \cdot \lambda_j e^{-\lambda_j x}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("HyperexpPdf(x, a, b): ", HyperexpPdf(x, a, b))
>>> print ("dist_hyperexponential(a, b).pdf(x): ", dist_hyperexponential(a, b).pdf(x))
6.356352346256452561561561561456 1356E+00
```

`math53.`**`hyperexponential_cdf`**(*lambdaj*, *wj*, *x*)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the hyperexponential distribution:

$$\text{cdf}(x) = \sum_{j=1}^{k} w_j(1 - e^{-\lambda_j x}) = -\sum_{j=1}^{k} w_j \cdot \text{expm1}(-\lambda_j x).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("HyperexpCdf(x, a, b): ", HyperexpCdf(x, a, b))
>>> print ("dist_hyperexponential(a, b).cdf(x): ", dist_hyperexponential(a, b).cdf(x))
6.356352346256452561561561561456 1356E+00
```

`math53.`**`hyperexponential_qtf`**(*lambdaj*, *wj*, *q*)

Returns qtf(q), the value of the quantile function (*Qtf*) of the hyperexponential distribution:

There is no known closed form for qtf(q). The function is computed with the starting value $x_0 = -\text{log1p}(-q) \sum_{j=1}^{k}(w_j/\lambda_j)$ using Newton iterations.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("HyperexpQtf(q, a, b): ", HyperexpQtf(q, a, b))
>>> print ("dist_hyperexponential(a, b).qtf(q): ", dist_hyperexponential(a, b).qtf(q))
6.356352346256452561561561561456 1356E+00
```

`class` `ctx.`**`dist_hyperexponential`**(*wj*, *lambdaj*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The hyperexponential distribution is a continuous probability mixture distribution with weights $w_j > 0$, rate parameters $\lambda_j > 0$, $j = 1 \ldots k$, and the support interval $(0, +\infty)$. The weights are interpreted as relative weights, to ensure that $\sum_{j=1}^{k} w_j = 1$.

It is called the hyperexponential distribution as it has a coefficient of variation greater than one, compared to the hypoexponential distribution which has coefficient of variation less than one and the exponential distribution which has coefficient of variation of one.

See also Wikipedia [1180], MathWorld [249], BoostMath [77].

`dist_hyperexponential.pdf(`x`)`

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a hyperexponential distribution:

$$\mathrm{pdf}_X(x) = \sum_{j=1}^{k} w_j \cdot \lambda_j e^{-\lambda_j x}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", mp_hyperexponential(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

`dist_hyperexponential.cdf(`x`)`

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a hyperexponential distribution:

$$\mathrm{cdf}_X(x) = \sum_{j=1}^{k} w_j(1 - e^{-\lambda_j x}) = -\sum_{j=1}^{k} w_j \cdot \mathrm{expm1}(-\lambda_j x).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", mp_hyperexponential(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

`dist_hyperexponential.sf(`x`)`

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following a hyperexponential distribution:

$$\mathrm{sf}_X(x) = 1 - \sum_{j=1}^{k} w_j(1 - e^{-\lambda_j x}) = \sum_{j=1}^{k} w_j \cdot \exp(-\lambda_j x).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", mp_hyperexponential(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

`dist_hyperexponential.qtf(`q`)`

Returns $\mathrm{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following a hyperexponential distribution.

There is no known closed form for $\mathrm{qtf}_X(q)$. The function is computed with the starting value $x_0 = -\mathrm{log1p}(-q)\sum_{j=1}^{k}(w_j/\lambda_j)$ using Newton iterations.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", mp_hyperexponential(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_hyperexponential.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following a hyperexponential distribution.

There is no known closed form for $\text{isf}_X(q)$. The function is computed with the starting value $x_0 = -\log(q)\sum_{j=1}^{k}(w_j/\lambda_j)$ using Newton iterations.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", mp_hyperexponential(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_hyperexponential.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a hyperexponential distribution:

$$C_X(t) = \sum_{j=1}^{k} w_j \frac{\lambda_j}{\lambda_j - it}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_hyperexponential(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_hyperexponential.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a hyperexponential distribution:

$$M_X(t) = \sum_{j=1}^{k} w_j \frac{\lambda_j}{\lambda_j - t}, \quad \text{for } \min(\lambda_j) > t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_hyperexponential(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_hyperexponential.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a hyperexponential distribution:

$$K_X(t) = \log\left[\sum_{j=1}^{k} w_j \frac{\lambda_j}{\lambda_j - t}\right], \quad \text{for } \min(\lambda_j) > t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", mp_hyperexponential(mu, sigma).k_x(t, k))
6.356352346256452561561561561356E+00
```

dist_hyperexponential.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a hyperexponential distribution:

$$\mu_X(r) = r! \sum_{j=1}^{k} \frac{w_j}{\lambda_j^r}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_hyperexponential(mu, sigma).moments(k))
6.356352346256452561561561561356E+00
```

dist_hyperexponential.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a hyperexponential distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_hyperexponential(mu, sigma).cumulants(k))
6.356352346256452561561561561356E+00
```

4.5.6 !!!Boost: Kumaraswamy distribution

The following functions return pdf, cdf, qtf or boost class of the Kumaraswamy distribution with shape parameters $a > 0$, $b > 0$, and the support interval $(0, 1)$.

See also Wikipedia [1185], MathWorld [252], Ehrhardt [297] (3.9.13).

See also: https://stats.stackexchange.com/questions/171952/parameter-estimation-for-kumaraswamy-distribution

See also: https://www.johndcook.com/blog/2009/11/24/kumaraswamy-distribution/

`math53.`**`kumaraswamy_pdf`**(a, b, x)

Returns pdf(x), the value of the probability density function (*Pdf*) of the Kumaraswamy distribution:

$$\text{pdf}(x) = abx^{a-1}(1-x^a)^{b-1} = abx^{a-1} \cdot (-\text{powm1}(x, a))^{b-1}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("KumaraswamyPdf(x, a, b): ", KumaraswamyPdf(x, a, b))
>>> print ("dist_kumaraswamy(a, b).pdf(x): ", dist_kumaraswamy(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`kumaraswamy_cdf`**(a, b, x)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the Kumaraswamy distribution:

$$\text{cdf}(x) = 1 - (1-x^a)^b = -\text{powm1}(-\text{powm1}(x, a), b).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("KumaraswamyCdf(x, a, b): ", KumaraswamyCdf(x, a, b))
>>> print ("dist_kumaraswamy(a, b).cdf(x): ", dist_kumaraswamy(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`kumaraswamy_qtf`**(a, b, q)

Returns qtf(q), the value of the quantile function (*Qtf*) of the Kumaraswamy distribution:

$$\text{qtf}(q) = (1-(1-q)^{\frac{1}{b}})^{\frac{1}{a}} = \text{pow}(-\text{pow1pm1}(-q, 1/b), 1/a).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("KumaraswamyQtf(q, a, b): ", KumaraswamyQtf(q, a, b))
>>> print ("dist_kumaraswamy(a, b).qtf(q): ", dist_kumaraswamy(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

`class` `ctx.`**`dist_kumaraswamy`**(a, b)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The Kumaraswamy distribution is a continuous probability distribution with shape parameters $a > 0$, $b > 0$, and the support interval $(0, 1)$. See also Wikipedia [1185], MathWorld [252].

dist_kumaraswamy.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Kumaraswamy distribution:

$$\text{pdf}_X(x) = abx^{a-1}(1-x^a)^{b-1} = abx^{a-1} \cdot (-\text{powm1}(x,a))^{b-1}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", mp_kumaraswamy(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_kumaraswamy.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Kumaraswamy distribution:

$$\text{cdf}_X(x) = 1-(1-x^a)^b = -\text{powm1}(-\text{powm1}(x,a),b).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", mp_kumaraswamy(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_kumaraswamy.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function function (sf) of a random variable X, following an Kumaraswamy distribution:

$$\text{sf}_X(x) = (1-x^a)^b = \text{pow}(-\text{powm1}(x,a),b).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", mp_kumaraswamy(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_kumaraswamy.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an Kumaraswamy distribution:

$$\text{qtf}_X(q) = (1-(1-q)^{\frac{1}{b}})^{\frac{1}{a}} = \text{pow}(-\text{pow1pm1}(-q,1/b),1/a).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", mp_kumaraswamy(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_kumaraswamy.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following an Kumaraswamy distribution:

$$\text{isf}_X(q) = (1-q^{\frac{1}{b}})^{\frac{1}{a}} = \text{pow}(-\text{powm1}(q,1/b),1/a).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", mp_kumaraswamy(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_kumaraswamy.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following an Kumaraswamy distribution:

$$C_X(t) = tbd$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_kumaraswamy(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_kumaraswamy.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following an Kumaraswamy distribution:

$$M_X(t) = tbd$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", mp_kumaraswamy(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_kumaraswamy.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an Kumaraswamy distribution:

$$K_X(t) = tbd$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", mp_kumaraswamy(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_kumaraswamy.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an Kumaraswamy distribution (Wikipedia). The central moments are calculated from the raw moments.

$$\mu_X(r) = \frac{b\Gamma(1 + n/a)\Gamma(b)}{\Gamma(1 + b + n/a)} = bB(1 + n/a, b).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_kumaraswamy(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_kumaraswamy.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an Kumaraswamy distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_kumaraswamy(mu, sigma).cumulants(k))
6.35635234625645256156156145561356E+00
```

4.5.7 Boost: Laplace distribution

The following functions return the pdf, cdf, qtf or boost class of the Laplace distribution with parameters $a \in \mathbb{R}$ (location), $b > 0$ (scale), and the support interval $(-\infty, +\infty)$.

See also Wikipedia [1159], MathWorld [828], BoostMath [60], Ehrhardt [297] (3.9.15).

`math53.laplace_pdf`(a, b, x)

Returns pdf(x), the value of the probability density function (*Pdf*) of the Laplace distribution:

$$\text{pdf}(x) = \exp(-|x - a|/b)/(2b).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("LaplacePdf(x, a, b): ", LaplacePdf(x, a, b))
>>> print ("dist_laplace(a, b).pdf(x): ", dist_laplace(a, b).pdf(x))
6.356352346256452561561561561456135 6E+00
```

`math53.laplace_cdf`(a, b, x)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the Laplace distribution:

$$\text{cdf}(x) = \begin{cases} \frac{1}{2} - \frac{1}{2}\text{expm1}\left(-\frac{x-a}{b}\right) & x \geq a \\ \frac{1}{2}\exp\left(-\frac{x-a}{b}\right) & x < a. \end{cases}$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("LaplaceCdf(x, a, b): ", LaplaceCdf(x, a, b))
>>> print ("dist_laplace(a, b).cdf(x): ", dist_laplace(a, b).cdf(x))
6.356352346256452561561561561456135 6E+00
```

`math53.laplace_qtf`(a, b, q)

Returns qtf(q), the value of the quantile function (*Qtf*) of the Laplace distribution:

$$\text{qtf}(q) = \begin{cases} a + b\ \log(2q), & q \leq 0.5, \\ a - b\ \log(2(1-q)) & q > 0.5. \end{cases}$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("LaplaceQtf(q, a, b): ", LaplaceQtf(q, a, b))
>>> print ("dist_laplace(a, b).qtf(q): ", dist_laplace(a, b).qtf(q))
6.356352346256452561561561561456135 6E+00
```

class `ctx.dist_laplace`(a, b)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The Laplace distribution is a continuous probability distribution with parameters $a \in \mathbb{R}$ (location), $b > 0$ (scale), and the support interval $(-\infty, +\infty)$. See also Wikipedia [1159], MathWorld [828], BoostMath [60], Witkovský [1473].

dist_laplace.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Laplace distribution:

$$\text{pdf}_X(x) = \exp(-|x-a|/b)/(2b).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", laplace(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_laplace.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Laplace distribution:

$$\text{cdf}_X(x) = \begin{cases} \frac{1}{2} - \frac{1}{2}\text{expm1}\left(-\frac{x-a}{b}\right) & x \geq a \\ \frac{1}{2}\exp\left(-\frac{x-a}{b}\right) & x < a. \end{cases}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", laplace(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_laplace.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following an Laplace distribution:

$$\text{sf}_X(x) = \begin{cases} \frac{1}{2} + \frac{1}{2}\text{expm1}\left(-\frac{x-a}{b}\right) & x \geq a \\ 1 - \frac{1}{2}\exp\left(-\frac{x-a}{b}\right) & x < a. \end{cases}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", laplace(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_laplace.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following an Laplace distribution:

$$\text{qtf}_X(q) = \begin{cases} a + b\ \log(2q), & q \leq 0.5, \\ a - b\ \log(2(1-q)) & q > 0.5. \end{cases}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", laplace(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_laplace.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following an Laplace distribution:

$$\text{isf}_X(q) = \begin{cases} a - b\ \log(2q), & q \leq 0.5, \\ a + b\ \log(2(1-q)) & q > 0.5. \end{cases}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", laplace(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_laplace.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an Laplace distribution:

$$C_X(t) = \frac{e^{iat}}{1 - b^2t^2}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", laplace(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_laplace.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following an Laplace distribution:

$$M_X(t) = \frac{e^{at}}{1 - b^2t^2}.$$

```

```

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", laplace(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_laplace.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an Laplace distribution:

$$K_X(t) = at - \log(1 - b^2t^2.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("k_x: ", laplace(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_laplace.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an Laplace distribution. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", laplace(mu, sigma).moments(k))
6.356352346256452561561561456l356E+00
```

dist_laplace.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an Laplace distribution. The cumulants are calculated from the moments.

$$\kappa_X(r) = \begin{cases} a & r = 1 \\ 0 & r = 2k + 1; k = 0, 1, \ldots \\ b^r 2(r-1)! & r = 2k; k = 0, 1, \ldots \end{cases}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", laplace(mu, sigma).cumulants(k))
6.356352346256452561561561456l356E+00
```

4.5.8 Boost: Logistic distribution

The following functions return the pdf, cdf, qtf or boost class of the logistic distribution with parameters $a \in \mathbb{R}$ (location), $b > 0$ (scale), and the support interval $(-\infty, +\infty)$.

See also Wikipedia [1161], MathWorld [831], BoostMath [62], Ehrhardt [297] (3.9.18).

`math53.logistic_pdf`(a, b, x)

Returns pdf(x), the value of the probability density function (*Pdf*) of the logistic distribution:

$$\text{pdf}(x) = \frac{1}{b} \frac{\exp\left(-\frac{x-a}{b}\right)}{\left(1+\exp\left(-\frac{x-a}{b}\right)\right)^2}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("LogisticPdf(x, a, b): ", LogisticPdf(x, a, b))
>>> print ("dist_logistic(a, b).pdf(x): ", dist_logistic(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.logistic_cdf`(a, b, x)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the logistic distribution:

$$\text{cdf}(x) = \frac{1}{1+\exp\left(-\frac{x-a}{b}\right)}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("LogisticCdf(x, a, b): ", LogisticCdf(x, a, b))
>>> print ("dist_logistic(a, b).cdf(x): ", dist_logistic(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.logistic_qtf`(a, b, q)

Returns qtf(q), the value of the quantile function (*Qtf*) of the logistic distribution:

$$\text{qtf}(q) = a + b \log\left(\frac{q}{1-q}\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("LogisticQtf(q, a, b): ", LogisticQtf(q, a, b))
>>> print ("dist_logistic(a, b).qtf(q): ", dist_logistic(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class `ctx.dist_logistic`(a, b)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The logistic distribution is a continuous probability distribution with parameters $a \in \mathbb{R}$ (location), $b > 0$ (scale), and the support interval $(-\infty, +\infty)$. See also Wikipedia [1161], MathWorld [831], BoostMath [62].

dist_logistic.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an logistic distribution:

$$\mathrm{pdf}_X(x) = \frac{1}{b}\frac{\exp\left(-\frac{x-a}{b}\right)}{\left(1+\exp\left(-\frac{x-a}{b}\right)\right)^2}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", logistic(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_logistic.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an logistic distribution:

$$\mathrm{cdf}_X(x) = \frac{1}{1+\exp\left(-\frac{x-a}{b}\right)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", logistic(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_logistic.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following an logistic distribution:

$$\mathrm{sf}_X(x) = \frac{1}{1+\exp\left(\frac{x-a}{b}\right)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", logistic(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_logistic.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following an logistic distribution:

$$\mathrm{qtf}_X(q) = a + b\,\log\left(\frac{q}{1-q}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", logistic(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_logistic.**isf**(*q*)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following an logistic distribution:

$$\text{isf}_X(q) = a - b \log\left(\frac{q}{1-q}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", logistic(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_logistic.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following an logistic distribution:

$$C_X(t) = e^{ita}\frac{\pi bt}{\sinh(\pi bt)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", logistic(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_logistic.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following an logistic distribution:

$$M_X(t) = e^{ta}\frac{\pi bt}{\sinh(\pi bt)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", logistic(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_logistic.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an logistic distribution:

$$K_X(t) = ta + \log(\pi bt) - \log(\sinh(\pi bt)).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", logistic(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_logistic.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an logistic distribution (Wikipedia). The raw moments are calculated from the central moments.

$$\mu_X(n) = b^n \pi^n (2^n - 2) \cdot |B_n|.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", logistic(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_logistic.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an logistic distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", logistic(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.5.9 Boost: Pareto distribution

The following functions return pdf, cdf, qtf or boost class of the Pareto distribution with minimum (real) value $k > 0$, shape $a > 0$, and the support interval $(k, +\infty)$.

See also Wikipedia [1169], MathWorld [836], BoostMath [68], Ehrhardt [297] (3.9.25).

`math53.pareto_pdf`(k, a, x)

Returns pdf(x), the value of the probability density function (*Pdf*) of the Pareto distribution:

$$\text{pdf}(x) = \frac{a}{x}\left(\frac{k}{x}\right)^a.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("ParetoPdf(x, a, b): ", ParetoPdf(x, a, b))
>>> print ("dist_pareto(a, b).pdf(x): ", dist_pareto(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.pareto_cdf`(k, a, x)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the Pareto distribution:

$$\text{cdf}(x) = 1 - \left(\frac{k}{x}\right)^a = -\text{powm1}(k/x, a).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("ParetoCdf(x, a, b): ", ParetoCdf(x, a, b))
>>> print ("dist_pareto(a, b).cdf(x): ", dist_pareto(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.pareto_qtf`(k, a, q)

Returns qtf(q), the value of the quantile function (*Qtf*) of the Pareto distribution:

$$\text{qtf}(q) = \frac{k}{(1-q)^{1/a}}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("ParetoQtf(q, a, b): ", ParetoQtf(q, a, b))
>>> print ("dist_pareto(a, b).qtf(q): ", dist_pareto(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class `ctx.dist_pareto`(k, a)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The Pareto distribution is a continuous probability distribution with minimum (real) value $k > 0$, shape $a > 0$, and the support interval $(k, +\infty)$. See also Wikipedia [1169], MathWorld [836], BoostMath [68], Witkovský [1478].

dist_pareto.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Pareto distribution:

$$\text{pdf}_X(x) = \frac{a}{x}\left(\frac{k}{x}\right)^a.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", pareto(mu, sigma).pdf(x))
6.356352346256452561561561561456 1356E-20
```

dist_pareto.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Pareto distribution:

$$\text{cdf}_X(x) = 1 - \left(\frac{k}{x}\right)^a = -\text{powm1}(k/x, a).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", pareto(mu, sigma).pdf(x))
6.356352346256452561561561561456 1356E-20
```

dist_pareto.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following an Pareto distribution:

$$\text{sf}_X(x) = \left(\frac{k}{x}\right)^a = \text{pow}(k/x, a).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", pareto(mu, sigma).pdf(x))
sf: 6.356352346256452561561561561456 1356E-20
```

dist_pareto.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following an Pareto distribution:

$$\text{qtf}_X(q) = \frac{k}{(1-q)^{1/a}}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", pareto(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561456 1356E+00
```

dist_pareto.**isf**(*q*)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following an Pareto distribution:

$$\text{isf}_X(q) = \frac{k}{q^{1/a}}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", pareto(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_pareto.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following an Pareto distribution:

$$C_X(t) = a(-ikt)^a\Gamma(-a, -ikt).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", pareto(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_pareto.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following an Pareto distribution:

$$M_X(t) = a(-kt)^a\Gamma(-a, -kt), \quad \text{for } t < 0.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", pareto(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_pareto.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an Pareto distribution:

$$K_X(t) = K_X(t) = \log(M_X(t)), \quad \text{for } t < 0.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", pareto(mu, sigma).k_x(t, k))
6.3563523462564525615615615614561356E+00
```

dist_pareto.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an Pareto distribution. The rth moments only exists for $n_2 > 2r$.

$$\mu'_X(r) = \frac{ak}{a-n} \quad \text{for } a > n.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", pareto(mu, sigma).moments(k))
6.356352346256452561561561456l356E+00
```

dist_pareto.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an Pareto distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", pareto(mu, sigma).cumulants(k))
6.356352346256452561561561456l356E+00
```

4.5.10 Boost: Rayleigh distribution

The following functions return the pdf, cdf, qtf or boost class of the Rayleigh distribution with scale $b > 0$ and the support interval $(0, +\infty)$.

See also Wikipedia [1192], MathWorld [838], BoostMath [85], Ehrhardt [297] (3.9.27).

`math53.`**`rayleigh_pdf`**(b, x)

Returns pdf(x), the value of the probability density function (*Pdf*) of the Rayleigh distribution:

$$\text{pdf}(x) = \frac{x}{b^2} \exp\left(-\frac{x^2}{2b^2}\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("RayleighPdf(x, a, b): ", RayleighPdf(x, a, b))
>>> print ("dist_rayleigh(a, b).pdf(x): ", dist_rayleigh(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`rayleigh_cdf`**(b, x)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the Rayleigh distribution:

$$\text{cdf}(x) = 1 - \exp\left(-\frac{x^2}{2b^2}\right) = -\text{expm1}\left(-\frac{x^2}{2b^2}\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("RayleighCdf(x, a, b): ", RayleighCdf(x, a, b))
>>> print ("dist_rayleigh(a, b).cdf(x): ", dist_rayleigh(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`rayleigh_qtf`**(b, q)

Returns qtf(q), the value of the quantile function (*Qtf*) of the Rayleigh distribution:

$$\text{qtf}(q) = b\sqrt{-2 \cdot \text{log1p}(-q)}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("RayleighQtf(q, a, b): ", RayleighQtf(q, a, b))
>>> print ("dist_rayleigh(a, b).qtf(q): ", dist_rayleigh(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

`class` `ctx.`**`dist_rayleigh`**(b)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The Rayleigh distribution is a continuous probability distribution with scale $b > 0$ and the support interval $(0, +\infty)$. See also Wikipedia [1192], MathWorld [838], BoostMath [85], Witkovský [1479].

dist_rayleigh.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Rayleigh distribution:

$$\mathrm{pdf}_X(x) = \frac{x}{b^2} \exp\left(-\frac{x^2}{2b^2}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", rayleigh(mu, sigma).pdf(x))
6.356352346256452561561561561456 1356E-20
```

dist_rayleigh.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Rayleigh distribution:

$$\mathrm{cdf}_X(x) = 1 - \exp\left(-\frac{x^2}{2b^2}\right) = -\mathrm{expm1}\left(-\frac{x^2}{2b^2}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", rayleigh(mu, sigma).pdf(x))
6.356352346256452561561561561456 1356E-20
```

dist_rayleigh.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following an Rayleigh distribution:

$$\mathrm{sf}_X(x) = \exp\left(-\frac{x^2}{2b^2}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", rayleigh(mu, sigma).pdf(x))
sf: 6.356352346256452561561561561456 1356E-20
```

dist_rayleigh.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following an Rayleigh distribution:

$$\mathrm{qtf}_X(q) = b\sqrt{-2 \cdot \mathrm{log1p}(-q)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", rayleigh(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561456 1356E+00
```

dist_rayleigh.**isf**(*q*)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following an Rayleigh distribution:

$$\text{isf}_X(q) = b\sqrt{-2 \cdot \log(q)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", rayleigh(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_rayleigh.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following an Rayleigh distribution:

$$C_X(t) = 1 + bte^{b^2t^2/2}\sqrt{\frac{\pi}{2}}\left(\text{erfi}\left(\frac{bt}{\sqrt{2}}\right) - i\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", rayleigh(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_rayleigh.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following an Rayleigh distribution:

$$M_X(t) = 1 + bte^{b^2t^2/2}\sqrt{\frac{\pi}{2}}\left(\text{erf}\left(\frac{bt}{\sqrt{2}}\right) + 1\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", rayleigh(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_rayleigh.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an Rayleigh distribution:

$$K_X(t) = K_X(t) = \log(M_X(t)).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", rayleigh(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_rayleigh.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an Rayleigh distribution.

$$\mu'_X(j) = b^j 2^{j/2}\Gamma(1 + j/2).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", rayleigh(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_rayleigh.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an Rayleigh distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", rayleigh(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.5.11 Boost: Triangular Distribution

The following functions return the pdf, cdf, qtf or boost class of the triangular distribution, with finite $a < b$, mode c, $a \le c \le b$, and the support interval $[a, b]$.

See also Wikipedia [1194], MathWorld [839], BoostMath [88], Ehrhardt [297] (3.9.30).

`math53.`**`triangular_pdf`**(*lower*, *mode*, *upper*, *x*)

Returns pdf(x), the value of the probability density function (*Pdf*) of the triangular distribution:

$$\text{pdf}(x) = \begin{cases} 0 & x < a \\ \frac{2(x-a)}{(b-a)(c-a)} & a \le x < c \\ \frac{2}{b-a} & x = c \\ \frac{2(b-x)}{(b-a)(b-c)} & c < x \le b \\ 0 & x > b \end{cases}$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("TriangularPdf(x, a, b): ", TriangularPdf(x, a, b))
>>> print ("dist_triangular(a, b).pdf(x): ", dist_triangular(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`triangular_cdf`**(*lower*, *mode*, *upper*, *x*)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the triangular distribution:

$$\text{cdf}(x) = \begin{cases} 0 & x < a \\ \frac{(x-a)^2}{(b-a)(c-a)} & a \le x < c \\ \frac{c-a}{b-a} & x = c \\ 1 - \frac{(b-x)^2}{(b-a)(b-c)} & c < x \le b \\ 1 & x > b \end{cases}$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("TriangularCdf(x, a, b): ", TriangularCdf(x, a, b))
>>> print ("dist_triangular(a, b).cdf(x): ", dist_triangular(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`triangular_qtf`**(*lower*, *mode*, *upper*, *q*)

Returns qtf(q), the value of the quantile function (*Qtf*) of the triangular distribution:

$$\text{qtf}(q) = \begin{cases} a + \sqrt{(b-a)(c-a)y} & y < (c-a)/(b-a) \\ c & y = (c-a)/(b-a) \\ b - \sqrt{(b-a)(b-c)(1-y)} & y > (c-a)/(b-a) \end{cases},$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("TriangularQtf(q, a, b): ", TriangularQtf(q, a, b))
>>> print ("dist_triangular(a, b).qtf(q): ", dist_triangular(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class ctx.**dist_triangular**(*lower*, *mode*, *upper*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The triangular distribution is a continuous probability distribution with finite $a < b$, mode c, $a \leq c \leq b$, and the support interval $[a, b]$. See also Wikipedia [1194], MathWorld [839], BoostMath [88], Witkovský [1482].

dist_triangular.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a triangular distribution:

$$\mathrm{pdf}_X(x) = \begin{cases} 0 & x < a \\ \frac{2(x-a)}{(b-a)(c-a)} & a \leq x < c \\ \frac{2}{b-a} & x = c \\ \frac{2(b-x)}{(b-a)(b-c)} & c < x \leq b \\ 0 & x > b \end{cases}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", triangular(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_triangular.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a triangular distribution:

$$\mathrm{cdf}_X(x) = \begin{cases} 0 & x < a \\ \frac{(x-a)^2}{(b-a)(c-a)} & a \leq x < c \\ \frac{c-a}{b-a} & x = c \\ 1 - \frac{(b-x)^2}{(b-a)(b-c)} & c < x \leq b \\ 1 & x > b \end{cases}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", triangular(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_triangular.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a triangular distribution:

$$\mathrm{sf}_X(x) = 1 - \mathrm{cdf}_X(x) = \int_x^\infty \mathrm{pdf}_X(x)\mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", triangular(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_triangular.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a triangular distribution:

$$\text{qtf}_X(q) = \begin{cases} a + \sqrt{(b-a)(c-a)y} & y < (c-a)/(b-a) \\ c & y = (c-a)/(b-a) \\ b - \sqrt{(b-a)(b-c)(1-y)} & y > (c-a)/(b-a) \end{cases},$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", triangular(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_triangular.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a triangular distribution:

$$\text{isf}_X(q) = \text{qtf}_X(1-q) = \text{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", triangular(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_triangular.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a triangular distribution:

$$C_X(t) = 2\frac{(b-c)e^{iat} - (b-a)e^{ict} + (c-a)e^{ibt}}{(b-a)(c-a)(b-c)t^2}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", triangular(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_triangular.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a triangular distribution:

$$M_X(t) = 2\frac{(b-c)e^{at} - (b-a)e^{ct} + (c-a)e^{bt}}{(b-a)(c-a)(b-c)t^2}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", triangular(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_triangular.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating functionof a random variable X, following a triangular distribution:

$$K_X(t) = \log\left[2\frac{(b-c)e^{at} - (b-a)e^{ct} + (c-a)e^{bt}}{(b-a)(c-a)(b-c)t^2}\right].$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", triangular(mu, sigma).k_x(t, k))
6.356352346256452561561561561456135 6E+00
```

dist_triangular.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a triangular distribution:

$$\mu'_{n+1} = \sum_{i=0}^{k} \binom{k}{i} (b-a)^i a^{k-1} \frac{2(1-\theta^{i+1})}{(i+1)(i+2)(1-\theta)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", triangular(mu, sigma).moments(k))
6.356352346256452561561561561456135 6E+00
```

dist_triangular.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a triangular distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", triangular(mu, sigma).cumulants(k))
6.356352346256452561561561561456135 6E+00
```

References:

Kotz Triangular (moments.)

4.5.12 Boost: Uniform distribution

Returns the pdf, cdf, qtf or boost class of a random variable X, following a uniform distribution on the support interval $[a, b]$ with finite $a < b$.

See also Wikipedia [1195], MathWorld [840], BoostMath [89], Team [537], Ehrhardt [297] (3.9.31).

`math53.`**`uniform_pdf`**(a, b, x)

Returns pdf(x), the value of the probability density function (*Pdf*) of the uniform distribution:

$$\text{pdf}(x) = \frac{1}{b-a}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("UniformPdf(x, a, b): ", UniformPdf(x, a, b))
>>> print ("dist_uniform(a, b).pdf(x): ", dist_uniform(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`uniform_cdf`**(a, b, x)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the uniform distribution:

$$\text{cdf}(x) = \frac{x-a}{b-a}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("UniformCdf(x, a, b): ", UniformCdf(x, a, b))
>>> print ("dist_uniform(a, b).cdf(x): ", dist_uniform(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`uniform_qtf`**(a, b, q)

Returns qtf(q), the value of the quantile function (*Qtf*) of the uniform distribution:

$$\text{qtf}(q) = a + q(b-a).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("UniformQtf(q, a, b): ", UniformQtf(q, a, b))
>>> print ("dist_uniform(a, b).qtf(q): ", dist_uniform(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

`class` `ctx.`**`dist_uniform`**$(lower, upper)$

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The uniform distribution is a continuous probability distribution on the support interval $[a, b]$ with finite $a < b$. See also Wikipedia [1195], MathWorld [840], BoostMath [89], Witkovský [1480], R (Statistical System) [537].

`dist_uniform.pdf(`x`)`

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a uniform distribution:

$$\mathrm{pdf}_X(x) = \frac{1}{b-a}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", uniform(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

`dist_uniform.cdf(`x`)`

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a uniform distribution:

$$\mathrm{cdf}_X(x) = \frac{1}{b-a}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", uniform(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

`dist_uniform.sf(`x`)`

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a uniform distribution:

$$\mathrm{sf}_X(x) = 1 - \mathrm{cdf}_X(x) = \int_x^{\infty} \mathrm{pdf}_X(x)\mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", uniform(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

`dist_uniform.qtf(`q`)`

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a uniform distribution:

$$\mathrm{qtf}_X(q) = \frac{x-a}{b-a}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", uniform(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

`dist_uniform.isf(`q`)`

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a uniform distribution:

$$\mathrm{isf}_X(q) = \mathrm{qtf}_X(1-q) = \mathrm{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", uniform(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_uniform.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following a uniform distribution:

$$C_X(t) = \frac{e^{itb} - e^{ita}}{it(b-a)}, \quad \text{for } t \neq 0, 0 \text{ otherwise.}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", uniform(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_uniform.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following a uniform distribution:

$$M_X(t) = \frac{e^{tb} - e^{ta}}{t(b-a)}, \quad \text{for } t \neq 0, 1 \text{ otherwise.}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", uniform(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_uniform.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a uniform distribution:

$$K_X(t) = K_X(t) = \log(M_X(t)).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", uniform(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_uniform.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a uniform distribution.

$$\mu'_X(n) = \frac{1}{n+1} \sum_{k=0}^{n} a^k b^{n-k}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", uniform(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_uniform.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a uniform distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", uniform(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.5.13 Boost: Weibull (Minimum-Type-III) distribution

The following functions return the pdf, cdf, qtf or boost class of the Weibull distribution with shape $a > 0$, scale $b > 0$, and the support interval $(0, +\infty)$.

See also Wikipedia [1196], MathWorld [841], BoostMath [90], Ehrhardt [297] (3.9.33).

math53.**weibull_pdf**(a, b, x)

Returns pdf(x), the value of the probability density function (*Pdf*) of the Weibull distribution:

$$\text{pdf}(x) = \frac{a}{x}\left(-\frac{x}{b}\right)^a \exp(-(x/b)^a).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("WeibullPdf(x, a, b): ", WeibullPdf(x, a, b))
>>> print ("dist_weibull(a, b).pdf(x): ", dist_weibull(a, b).pdf(x))
6.356352346256452561561561561456 1356E+00
```

math53.**weibull_cdf**(a, b, x)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the Weibull distribution:

$$\text{cdf}(x) = 1 - \exp\left(-(x/b)^a\right) = -\text{expm1}\left(-(x/b)^a\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("WeibullCdf(x, a, b): ", WeibullCdf(x, a, b))
>>> print ("dist_weibull(a, b).cdf(x): ", dist_weibull(a, b).cdf(x))
6.356352346256452561561561561456 1356E+00
```

math53.**weibull_qtf**(a, b, q)

Returns qtf(q), the value of the quantile function (*Qtf*) of the Weibull distribution:

$$\text{qtf}(q) = b \cdot (-\text{log1p}(-q))^{1/a}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("WeibullQtf(q, a, b): ", WeibullQtf(q, a, b))
>>> print ("dist_weibull(a, b).qtf(q): ", dist_weibull(a, b).qtf(q))
6.356352346256452561561561561456 1356E+00
```

class ctx.**dist_weibull**(a, b)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The Weibull distribution is a continuous probability distribution with shape $a > 0$, scale $b > 0$, and the support interval $(0, +\infty)$. See also Wikipedia [1196], MathWorld [841], BoostMath [90], Witkovský [1483], R (Statistical System) [538].

`dist_weibull.pdf(`x`)`

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a Weibull distribution:

$$\text{pdf}_X(x) = \frac{a}{x}\left(-\frac{x}{b}\right)^a \exp(-(x/b)^a).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", weibull(mu, sigma).pdf(x))
6.356352346256452561561561456135 6E-20
```

`dist_weibull.cdf(`x`)`

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Weibull distribution:

$$\text{cdf}_X(x) = 1 - \exp\left(-(x/b)^a\right) = -\text{expm1}\left(-(x/b)^a\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", weibull(mu, sigma).pdf(x))
6.356352346256452561561561456135 6E-20
```

`dist_weibull.sf(`x`)`

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following a Weibull distribution:

$$\text{sf}_X(x) = \exp\left(-(x/b)^a\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", weibull(mu, sigma).pdf(x))
sf: 6.356352346256452561561561456135 6E-20
```

`dist_weibull.qtf(`q`)`

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Weibull distribution:

$$\text{qtf}_X(q) = b \cdot \left(-\text{log1p}(-q)\right)^{1/a}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", weibull(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561456135 6E+00
```

`dist_weibull.isf(`q`)`

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Weibull distribution:

$$\text{isf}_X(q) = b \cdot \left(-\log(q)\right)^{1/a}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", weibull(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_weibull.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Weibull distribution:

$$C_X(t) = \sum_{n=0}^{\infty} \frac{(it)^n \lambda^n}{n!} \Gamma(1 + n/k).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", weibull(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_weibull.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following a Weibull distribution:

$$M_X(t) = \sum_{n=0}^{\infty} \frac{t^n \lambda^n}{n!} \Gamma(1 + n/k), k \geq 1.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", weibull(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_weibull.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a Weibull distribution:

$$K_X(t) = K_X(t) = \log(M_X(t)).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", weibull(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_weibull.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Weibull distribution.

$$\mu'_X(r) = \sum_{j=0}^{r} \binom{r}{j} \Gamma\left(\frac{r-j}{k} + 1\right) \lambda^{r-j}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", weibull(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_weibull.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a Weibull distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", weibull(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.5.14 Dagum (Burr Type III) distribution

class ctx.**dist_dagum**(*n1*, *n2*, *lambda*, ***kwargs*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

These functions return PDF, CDF, and ICDF of the Dagum distribution with location $a > 0$, scale $b > 0$, and the support interval $(0, +\infty)$.

See also: Wikipedia [1200], Kleiber and Kotz [393], Dagum [194].

dist_dagum.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Dagum distribution:

$$\mathrm{pdf}_X(x) = f(x; a, b, p) = \frac{ap}{x} \frac{(x/b)^{ap}}{((x/b)^a + 1)^{p+1}}.$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", dist_dagum(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_dagum.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Dagum distribution:

$$\mathrm{cdf}_X(x) = \left[1 + \left(\frac{x}{b}\right)^{-a}\right]^{-p} \quad \text{for } x > 0, \text{ where } a, b, p > 0$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", dist_dagum(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_dagum.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following an Dagum distribution:

$$\mathrm{sf}_X(x) = 1 - \left[1 + \left(\frac{x}{b}\right)^{-a}\right]^{-p}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", dist_dagum(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_dagum.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an Dagum distribution:

$$\mathrm{qtf}_X(q) = b(q^{-1/p} - 1)^{-1/a}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", dist_dagum(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561456 1356E+00
```

dist_dagum.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following an Dagum distribution:

$$\text{isf}_X(q) = b((1-q)^{-1/p} - 1)^{-1/a}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", dist_dagum(mu, sigma).isf(q))
6.356352346256452561561561456 1356E+00
```

dist_dagum.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an Dagum distribution:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \text{d}x$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_dagum(mu, sigma).c_x(t))
6.356352346256452561561561456 1356E+00
```

dist_dagum.**m_x**(t)

Returns None, since the moment generating function does not exist.

dist_dagum.**k_x**(t, *k=0*)

Returns None, since the cumulant generating function does not exist.

dist_dagum.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an Dagum distribution (see Kleiber_2007_Dagum_moments). The kth moment exists for $-ap < k < a$ and equals

$$\mu_k = \frac{b^k \Gamma(p + k/a)\Gamma(1 - k/a)}{\Gamma(p)}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_dagum(mu, sigma).moments(k))
6.356352346256452561561561456 1356E+00
```

dist_dagum.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an Dagum distribution. The cumulants are calculated from the moments.

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_dagum(mu, sigma).cumulants(k))
6.3563523462564525615615615614561356E+00
```

4.5.15 Fisk (log-logistic) distribution

class ctx.**dist_fisk**(*n1*, *n2*, *lambda*, ***kwargs*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The Fisk distribution is a continuous probability distribution with scale parameter $a > 0$, shape parameter $b > 0$, and the support interval $[0, +\infty)$.

See also: Wikipedia [1216], Kleiber and Kotz [393].

dist_fisk.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Fisk distribution:

$$\mathrm{pdf}_X(x) = f(x;\alpha,\beta) = \frac{(\beta/\alpha)(x/\alpha)^{\beta-1}}{\left(1+(x/\alpha)^{\beta}\right)^2}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", dist_fisk(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_fisk.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Fisk distribution:

$$\mathrm{cdf}_X(x) = \frac{1}{1+(x/\alpha)^{-\beta}} = \frac{x^{\beta}}{\alpha^{\beta}+x^{\beta}}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", dist_fisk(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_fisk.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following an Fisk distribution:

$$\mathrm{sf}_X(x) = 1 - \frac{1}{1+(x/\alpha)^{-\beta}} = 1 - \frac{x^{\beta}}{\alpha^{\beta}+x^{\beta}}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", dist_fisk(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_fisk.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an Fisk distribution:

$$\mathrm{qtf}_X(q) = \alpha\left(\frac{p}{1-p}\right)^{1/\beta}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", dist_fisk(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561456 1356E+00
```

dist_fisk.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following an Fisk distribution:

$$\text{isf}_X(q) = \alpha \left(\frac{q}{1-q} \right)^{1/\beta}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", dist_fisk(mu, sigma).isf(q))
6.356352346256452561561561456 1356E+00
```

dist_fisk.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an Fisk distribution:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \mathrm{d}x$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_fisk(mu, sigma).c_x(t))
6.356352346256452561561561456 1356E+00
```

dist_fisk.**m_x**(t)

Returns None, since the moment generating function does not exist.

dist_fisk.**k_x**(t, *k=0*)

Returns None, since the cumulant generating function does not exist.

dist_fisk.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an Fisk distribution (see Kleiber_2007_Dagum_moments). The kth raw moment exists only when $k < \beta$, when it is given by

$$\mu_k = \alpha^k \frac{k\pi/\beta}{\sin(k\pi/\beta)}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_fisk(mu, sigma).moments(k))
6.356352346256452561561561456 1356E+00
```

dist_fisk.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an Fisk distribution. The cumulants are calculated from the moments.

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_fisk(mu, sigma).cumulants(k))
6.3563523462564525615615615614561356E+00
```

4.5.16 Fréchet (Maximum/Minimum-Type-II or Inverse Weibull) distribution

class ctx.**dist_frechet**(a, b=*1*)

The Fréchet distribution is a continuous probability distribution with shape parameters a and b, and the support interval $(0, +\infty)$. If $b = 1$ this is the classical Fréchet distribution. For $b \neq 1$ this is also called reciprocal Weibull distribution or the generalized inverse Weibull distribution ([DeGusmao2011`).

See also: Wikipedia [1206], De Gusmao *et al.* [205], Kleiber and Kotz [393],

TODO: remove m and s from these formulas, use formulas from De Gusmao *et al.* [205].

Note: α in Wikipedia corresponds to $-\beta$ in De Gusmao *et al.* [205].

dist_frechet.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Fréchet distribution:

$$\mathrm{pdf}_X(x) = \frac{\alpha}{s}\left(\frac{x-m}{s}\right)^{-1-\alpha} e^{-(\frac{x-m}{s})^{-\alpha}}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", dist_frechet(mu, sigma).pdf(x))
6.356352346256452561561561561456 1356E-20
```

dist_frechet.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Fréchet distribution:

$$\mathrm{cdf}_X(x) = e^{-(\frac{x-m}{s})^{-\alpha}}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", dist_frechet(mu, sigma).pdf(x))
6.356352346256452561561561561456 1356E-20
```

dist_frechet.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following an Fréchet distribution:

$$\mathrm{sf}_X(x) = 1 - e^{-(\frac{x-m}{s})^{-\alpha}}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", dist_frechet(mu, sigma).pdf(x))
sf: 6.356352346256452561561561561456 1356E-20
```

dist_frechet.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an Fréchet distribution:

$$\mathrm{qtf}_X(q) = m + s\left(-\log(q)\right)^{-1/a}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", dist_frechet(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_frechet.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following an Fréchet distribution:

$$\text{isf}_X(q) = m + s\left(-\log(1-q)\right)^{-1/a}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", dist_frechet(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_frechet.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an Fréchet distribution:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \mathrm{d}x$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_frechet(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_frechet.**m_x**(t)

Returns None, since the moment generating function does not exist.

dist_frechet.**k_x**(t, *k=0*)

Returns None, since the cumulant generating function does not exist.

dist_frechet.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an Fréchet distribution. Moments exist only for $a > k$.

$$\mu_k = a^k \Gamma(1 - kb^{-1})$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_frechet(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_frechet.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an Fréchet distribution. The cumulants are calculated from the moments.

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_frechet(mu, sigma).cumulants(k))
6.356352346256452561561561561456 1356E+00
```

4.5.17 Generalized Extreme Value (Maximum) or GEV distribution

class ctx.**dist_gev**(*n1*, *n2*, *lambda*, ***kwargs*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

These functions return PDF, CDF, and ICDF of the GEV distribution with location a, scale $b > 0$, and the support interval $(-\infty, +\infty)$:

See also: Wikipedia [1207], Kleiber and Kotz [393], Kotz and Nadarajah [398], Coles [184].

Extreme value theory studies the statistical behaviour of $M_n = \max\{X_1, \ldots, X_n\}$, or $M_n = \min\{X_1, \ldots, X_n\}$, where $\{X_1, \ldots, X_n\}$ is a sequence of independent random variables having a common distribution function F.

If there exist sequences of constants $\{a_n\}$ and $\{b_n\}$ such that $\lim_{n\to\infty} P\{(M_n - b_n)/a_n \le z\} = G(z)$, where G is a non-degenerate distribution function (this assumption is called the stability postulate), then G belongs to the Gumbel, Fréchet or Weibull family of distributions.

The following table summarizes the forms of limiting distributions for maxima and minima for seven widely used continuous distributions:

Initial Distribution	Limiting distribution for maxima	Limiting distribution for minima
Exponential	Type 1 (Gumbel)	Type 3 (Weibull)
Gamma	Type 1 (Gumbel)	Type 3 (Weibull)
Normal	Type 1 (Gumbel)	Type 1 (Gumbel)
Log-Normal	Type 1 (Gumbel)	Type 1 (Gumbel)
Uniform	Type 3 (Weibull)	Type 3 (Weibull)
Pareto	Type 2 (Fréchet)	Type 3 (Weibull)
Cauchy	Type 2 (Fréchet)	Type 2 (Fréchet)

dist_gev.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an GEV distribution:

$$\text{pdf}_X(x) = \text{cdf}_X(x) \times \begin{cases} \left(1 - c\dfrac{x-a}{b}\right)^{1/c-1} & \text{for } c \neq 0 \\ \exp\left(-\dfrac{x-a}{b}\right) & \text{for } c = 0 \end{cases}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", dist_gev(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

`dist_gev.cdf(`x`)`

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an GEV distribution:

$$\mathrm{cdf}_X(x) = \begin{cases} \exp\left(1 - c\frac{x-a}{b}\right)^{1/c} & \text{for } c \neq 0 \\ \exp\left(-\exp\left(-\frac{x-a}{b}\right)\right) & \text{for } c = 0 \end{cases}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", dist_gev(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

`dist_gev.sf(`x`)`

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following an GEV distribution:

$$\mathrm{sf}_X(x) = \begin{cases} 1 - \exp\left(1 - c\frac{x-a}{b}\right)^{1/c} & \text{for } c \neq 0 \\ 1 - \exp\left(-\exp\left(-\frac{x-a}{b}\right)\right) & \text{for } c = 0 \end{cases}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", dist_gev(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

`dist_gev.qtf(`q`)`

Returns $\mathrm{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an GEV distribution:

$$\mathrm{qtf}_X(x) = \begin{cases} a + \frac{b}{c}\left(1 - \log(q)\right)^c) & \text{for } c \neq 0 \\ a - b\log(-\log(q)) & \text{for } c = 0 \end{cases}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", dist_gev(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

`dist_gev.isf(`q`)`

Returns $\mathrm{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following an GEV distribution:

$$\mathrm{isf}_X(x) = \begin{cases} a + \frac{b}{c}\left(1 - \log(1-q)\right)^c) & \text{for } c \neq 0 \\ a - b\log(-\log(1-q)) & \text{for } c = 0 \end{cases}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", dist_gev(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_gev.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following an GEV distribution:

$$C_X(t) = \int_0^\infty e^{itx} \mathrm{pdf}_X(x) \mathrm{d}x$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_gev(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_gev.**m_x**(*t*)

Returns None, since the moment generating function does not exist.

dist_gev.**k_x**(*t*, *k=0*)

Returns None, since the cumulant generating function does not exist.

dist_gev.**moments**(*k*)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an GEV distribution (see Kleiber_2007_Dagum_moments). The kth moment exists for $-ap < k < a$ and equals

$$\mu_k = ??$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_gev(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_gev.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an GEV distribution. The cumulants are calculated from the moments.

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_gev(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.5.18 Generalized Pareto distribution

class ctx.**dist_genpareto**(*n1*, *n2*, *lambda*, ***kwargs*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

These functions return PDF, CDF, and ICDF of the Generalized Pareto distribution with parameters mu in mathbb R, sigma >0`, and $c \in \mathbb{R}$, where the support of $x \geq \mu$ when $c \geq 0$, and $\mu \leq x \leq \mu - \sigma/c$ when $c < 0$.

See also: Wikipedia [1208], Pires *et al.* [473], Kleiber and Kotz [393],

dist_genpareto.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a Generalized Pareto distribution:

$$\mathrm{pdf}_X(x) = f_c(z) = \begin{cases} (1+cz)^{-\frac{c+1}{c}} & \text{for } c \neq 0, \\ e^{-z} & \text{for } c = 0. \end{cases}, \quad \text{where } z = \frac{x-\mu}{\sigma}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", dist_genpareto(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_genpareto.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Generalized Pareto distribution:

$$\mathrm{cdf}_X(x) = \begin{cases} 1-(1+cz)^{-1/c} & \text{for } c \neq 0, \\ 1-\exp(-z) & \text{for } c = 0, \end{cases}, \quad \text{where } z = \frac{x-\mu}{\sigma}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", dist_genpareto(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_genpareto.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following a Generalized Pareto distribution:

$$\mathrm{sf}_X(x) = \begin{cases} (1+cz)^{-1/c} & \text{for } c \neq 0, \\ \exp(-z) & \text{for } c = 0, \end{cases}, \quad \text{where } z = \frac{x-\mu}{\sigma}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", dist_genpareto(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_genpareto.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following a Generalized Pareto distribution:

$$\mathrm{qtf}_X(q) = \mu + \sigma \times \begin{cases} \dfrac{(1-q)^{-c}-1}{c} & \text{for } c \neq 0, \\ -\log(1-q) & \text{for } c = 0, \end{cases}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", dist_genpareto(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561456 1356E+00
```

dist_genpareto.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following a Generalized Pareto distribution:

$$\text{isf}_X(q) = \mu + \sigma \times \begin{cases} \dfrac{(q)^{-c} - 1}{c} & \text{for } c \neq 0, \\ -\log(q) & \text{for } c = 0, \end{cases}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", dist_genpareto(mu, sigma).isf(q))
6.356352346256452561561561456 1356E+00
```

dist_genpareto.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Generalized Pareto distribution:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \mathrm{d}x$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_genpareto(mu, sigma).c_x(t))
6.356352346256452561561561456 1356E+00
```

dist_genpareto.**m_x**(t)

Returns None, since the moment generating function does not exist.

dist_genpareto.**k_x**(t, *k=0*)

Returns None, since the cumulant generating function does not exist.

dist_genpareto.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Generalized Pareto distribution (see Kleiber_2007_Dagum_moments). The rth moment exists for $c < 1/r$ and equals

$$\mu_k = \frac{r! \sigma!}{\prod_{i=1}^{r} (1 - ic)}.$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_genpareto(mu, sigma).moments(k))
6.356352346256452561561561456 1356E+00
```

dist_genpareto.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a Generalized Pareto distribution. The cumulants are calculated from the moments.

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_genpareto(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.5.19 Gompertz-Makeham distribution

class ctx.**dist_gompertz**(*a*, *b*, *lambda1=0*, ***kwargs*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

Gompertz-Makeham distribution is a continuous probability distribution with parameters $a > 0, b > 0, \lambda \geq 0$, and the support interval $(0, +\infty)$. The hazard function has the form $\mathrm{hf}_X(x) = ae^{bx} + \lambda$.

See also: Wikipedia [1209], MathWorld [248], Jodrá [385], Riffi [480].

dist_gompertz.**pdf**(*x*)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Gompertz-Makeham distribution:

$$\mathrm{pdf}_X(x) = \mathrm{hf}_X(x) \cdot \mathrm{sf}_X(x) = (ae^{bx} + \lambda) \cdot \exp\left[-\lambda x - \frac{a}{b}\left(e^{bx} - 1\right)\right]$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", dist_gompertz(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_gompertz.**cdf**(*x*)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Gompertz-Makeham distribution:

$$\mathrm{cdf}_X(x) = 1 - \exp\left[-\lambda x - \frac{a}{b}\left(e^{bx} - 1\right)\right] = -\mathrm{expm1}\left[-\lambda x - \frac{a}{b}\left(\mathrm{expm1}(bx)\right)\right]$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", dist_gompertz(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_gompertz.**sf**(*x*)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following an Gompertz-Makeham distribution:

$$\mathrm{sf}_X(x) = \exp\left[-\lambda x - \frac{a}{b}\left(e^{bx} - 1\right)\right] = \exp\left[-\lambda x - \frac{a}{b}\left(\mathrm{expm1}(bx)\right)\right]$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", dist_gompertz(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_gompertz.**qtf**(*q*)

Returns $\mathrm{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an Gompertz-Makeham distribution:

$$\mathrm{qtf}_X(q) = \begin{cases} \dfrac{1}{b}\mathrm{log1p}\left(-\dfrac{b}{a}\,\mathrm{log1p}(-q)\right) & \text{for } \lambda = 0, \\ \dfrac{a}{b\lambda} - \dfrac{1}{\lambda}\mathrm{log1p}(-q) - \dfrac{1}{b}W_0\left(\dfrac{a}{\lambda}e^{a/\lambda} \cdot \mathrm{pow1p}(-q, -b/\lambda)\right) & \text{for } \lambda > 0, \end{cases}$$

where W_0 denotes the principal branch of the Lambert W function (see ...).

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", dist_gompertz(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

`dist_gompertz.isf(q)`

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following an Gompertz-Makeham distribution:

$$\text{isf}_X(q) = \begin{cases} \frac{1}{b}\text{log1p}\left(-\frac{b}{a}\log(q)\right) & \text{for } \lambda = 0, \\ \frac{a}{b\lambda} - \frac{1}{\lambda}\log(q) - \frac{1}{b}W_0\left(\frac{a}{\lambda}e^{a/\lambda}\cdot q^{-b/\lambda}\right) & \text{for } \lambda > 0, \end{cases}$$

where W_0 denotes the principal branch of the Lambert W function (see ...).

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", dist_gompertz(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

`dist_gompertz.c_x(t)`

Returns $C_X(t)$, the characteristic function of a random variable X, following an Gompertz-Makeham distribution:

$$C_X(t) = e^d\left(d\cdot E_{p(it)}(d) + \frac{\lambda}{b}E_{1+p(it)}(d)\right), \quad \text{where } p(it) = \frac{\lambda - it}{b} \text{and } d = \frac{a}{b}.$$

Here $E_p(z)$ denotes the exponential integral, defined as $E_p(z) = z^{p-1}\Gamma(1-p,z) = z^{p-1}e^{-z}U(p,p,z)$. $\Gamma(\cdot)$ denotes the incomplete gamma function (see ...), and $U(\cdot)$ denotes Tricomi's hypergeometric function (see ...).

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_gompertz(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

`dist_gompertz.m_x(t)`

Returns $M_X(t)$, the moment generating function of a random variable X, following an Gompertz-Makeham distribution:

$$M_X(t) = e^d\left(d\cdot E_{p(t)}(d) + \frac{\lambda}{b}E_{1+p(t)}(d)\right), \quad \text{where } p(t) = \frac{\lambda - t}{b} \text{and } d = \frac{a}{b}.$$

Here $E_p(z)$ denotes the exponential integral, defined as $E_p(z) = z^{p-1}\Gamma(1-p,z) = z^{p-1}e^{-z}U(p,p,z)$. $\Gamma(\cdot)$ denotes the incomplete gamma function (see ...), and $U(\cdot)$ denotes Tricomi's hypergeometric function (see ...).

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_gompertz(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_gompertz.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an Gompertz-Makeham distribution:

$$K_X(t) = \log(M_X(t))$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_gompertz(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_gompertz.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \dots k$, of a random variable X, following an Gompertz-Makeham distribution. The moments are calculated from their definition:

$$\mu'_X(r) = E(X^r) = \int_0^1 x^r \text{pdf}_X(x) \text{d}x$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_gompertz(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_gompertz.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \dots k$, of a random variable X, following an Gompertz-Makeham distribution. The cumulants are calculated from the moments.

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_gompertz(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.5.20 Lomax distribution

class ctx.**dist_lomax**(*n1*, *n2*, *lambda*, ***kwargs*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

These functions return PDF, CDF, and ICDF of the Lomax distribution with location a, scale $b > 0$, and the support interval $(-\infty, +\infty)$:

See also: Wikipedia [1217], Kleiber and Kotz [393],

dist_lomax.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Lomax distribution:

$$\mathrm{pdf}_X(x) = \frac{a}{b}\left(1 + \frac{x}{b}\right)^{-(a+1)}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", dist_lomax(mu, sigma).pdf(x))
6.356352346256452561561561561456135 6E-20
```

dist_lomax.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Lomax distribution:

$$\mathrm{cdf}_X(x) = 1 - \left(1 + \frac{x}{b}\right)^{-a}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", dist_lomax(mu, sigma).pdf(x))
6.356352346256452561561561561456135 6E-20
```

dist_lomax.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following an Lomax distribution:

$$\mathrm{sf}_X(x) = \left(1 + \frac{x}{b}\right)^{-a}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", dist_lomax(mu, sigma).pdf(x))
sf: 6.356352346256452561561561561456135 6E-20
```

dist_lomax.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an Lomax distribution:

$$\mathrm{qtf}_X(q) = b\left((1-p)^{-\frac{1}{a}} - 1\right)$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", dist_lomax(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561456 1356E+00
```

dist_lomax.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following an Lomax distribution:

$$\text{isf}_X(q) = b\left((1-q)^{-\frac{1}{a}} - 1\right)$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", dist_lomax(mu, sigma).isf(q))
6.356352346256452561561561561456 1356E+00
```

dist_lomax.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an Lomax distribution:

$$C_X(t) = \int_0^\infty e^{itx}\text{pdf}_X(x)\mathrm{d}x$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_lomax(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

dist_lomax.**m_x**(t)

Returns None, since the moment generating function does not exist.

dist_lomax.**k_x**(t, *k=0*)

Returns None, since the cumulant generating function does not exist.

dist_lomax.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an Lomax distribution (see Kleiber_2007_Dagum_moments). The kth moment exists for $-k < a$ and equals

$$\mu_k = \frac{b^k\Gamma(a-k)\Gamma(1+k)}{\Gamma(a)}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_lomax(mu, sigma).moments(k))
6.356352346256452561561561561456 1356E+00
```

dist_lomax.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an Lomax distribution. The cumulants are calculated from the moments.

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_lomax(mu, sigma).cumulants(k))
6.356352346256452561561561561456l356E+00
```

4.5.21 Shifted Gompertz distribution

class ctx.**dist_shifted_gompertz**(*a*, *b*, *lambda1=0*, ***kwargs*)

Shifted Gompertz distribution is a continuous probability distribution with parameters $a > 0, b > 0$, and the support interval $[0, +\infty)$.

See also: Wikipedia [1219], MathWorld [255], Jiménez and Pedro Jodrá [381], Jiménez Torres [382].

dist_shifted_gompertz.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Shifted Gompertz distribution:

$$\mathrm{pdf}_X(x) = be^{-(bx+ae^{-bx})}\left(1 + a\left(1 - e^{-bx}\right)\right), \quad x > 0.$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", dist_shifted_gompertz(mu, sigma).pdf(x))
6.356352346256452561561561561456 1356E-20
```

dist_shifted_gompertz.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Shifted Gompertz distribution:

$$\mathrm{cdf}_X(x) = \left(1 - e^{-bx}\right)e^{-ae^{-bx}}, \quad x > 0.$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", dist_shifted_gompertz(mu, sigma).pdf(x))
6.356352346256452561561561561456 1356E-20
```

dist_shifted_gompertz.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following an Shifted Gompertz distribution:

$$\mathrm{sf}_X(x) = 1 - \left(1 - e^{-bx}\right)e^{-ae^{-bx}}, \quad x > 0.$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", dist_shifted_gompertz(mu, sigma).pdf(x))
sf: 6.356352346256452561561561561456 1356E-20
```

dist_shifted_gompertz.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an Shifted Gompertz distribution:

$$\mathrm{qtf}_X(q) = \frac{1}{b}\log\left(1 - \frac{W_0(ae^a q)}{a}\right)$$

where W_0 denotes the principal branch of the Lambert W function (see ...).

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", dist_shifted_gompertz(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

`dist_shifted_gompertz.isf(`q`)`

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following an Shifted Gompertz distribution:

$$\text{isf}_X(q) = \frac{1}{b} \log\left(1 - \frac{W_0(ae^a(1-q))}{a}\right)$$

where W_0 denotes the principal branch of the Lambert W function (see ...).

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", dist_shifted_gompertz(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

`dist_shifted_gompertz.c_x(`t`)`

Returns $C_X(t)$, the characteristic function of a random variable X, following an Shifted Gompertz distribution:

$$C_X(t) = a^{it/(b-1)}(a + it/b)\Gamma(1 - it/b, a) + e^{-a}.$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_shifted_gompertz(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

`dist_shifted_gompertz.m_x(`t`)`

Returns $M_X(t)$, the moment generating function of a random variable X, following an Shifted Gompertz distribution:

$$M_X(t) = a^{t/(b-1)}(a + t/b)\Gamma(1 - t/b, a) + e^{-a}.$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_shifted_gompertz(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

`dist_shifted_gompertz.k_x(`t`, k=0)`

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an Shifted Gompertz distribution:

$$K_X(t) = \log(M_X(t))$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_shifted_gompertz(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_shifted_gompertz.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an Shifted Gompertz distribution. The moments are calculated from their definition:

$$\mu'_X(r) = E(X^r) = \int_0^1 x^r \mathrm{pdf}_X(x) \mathrm{d}x$$

There is an explicit expression for the mean:

$$\mu'_X(1) = E(X) = \frac{1}{b}\left(\gamma + \log(a) + \frac{1 - e^{-a}}{a} + E_1(a)\right).$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_shifted_gompertz(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_shifted_gompertz.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an Shifted Gompertz distribution. The cumulants are calculated from the moments.

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_shifted_gompertz(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.5.22 Singh-Maddala (Burr Type XII) distribution

class ctx.**dist_singh_maddala**(*n1*, *n2*, *lambda*, ***kwargs*)

These functions return PDF, CDF, and ICDF of the Singh-Maddala distribution with location a, scale $b > 0$, and the support interval $(-\infty, +\infty)$:

See also: Wikipedia [1199], Rodriguez [484], Kleiber and Kotz [393] (page 198), Kumar [402],

dist_singh_maddala.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Singh-Maddala distribution:

$$\text{pdf}_X(x) = f(x; c, d) = \frac{adx^{a-1}}{b^a(1 + (x/b)^a)^{1+d}}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", dist_singh_maddala(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_singh_maddala.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Singh-Maddala distribution:

$$\text{cdf}_X(x) = 1 - (1 + (x/b)^a)^{-d}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", dist_singh_maddala(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_singh_maddala.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function function (sf) of a random variable X, following an Singh-Maddala distribution:

$$\text{sf}_X(x) = (1 + (x/b)^a)^{-d}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", dist_singh_maddala(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_singh_maddala.**qtf**(d)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an Singh-Maddala distribution:

$$\text{qtf}_X(q) = b[(1 - q)^{-1/d} - 1]^{1/a}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; d = 0.3;
>>> print ("qtf: ", dist_singh_maddala(mu, sigma).qtf(d))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_singh_maddala.**isf**(d)

Returns $\text{isf}_X(d)$, the inverse survival function function (isf) of a random variable X, following an Singh-Maddala distribution:

$$\text{isf}_X(d) = b[(1-q)^{-1/d} - 1]^{1/a}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; d = 0.3;
>>> print ("isf: ", dist_singh_maddala(mu, sigma).isf(d))
6.35635234625645256156156145613 56E+00
```

dist_singh_maddala.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an Singh-Maddala distribution:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \mathrm{d}x$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_singh_maddala(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_singh_maddala.**m_x**(t)

Returns None, since the moment generating function does not exist.

dist_singh_maddala.**k_x**(t, *k=0*)

Returns None, since the cumulant generating function does not exist.

dist_singh_maddala.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an Singh-Maddala distribution. The kth moment exists for $-a < k < aq$; it equals (see Kleiber(2003), page 201)

$$\mu_n = \frac{b^k \Gamma(1 + k/a) \Gamma(d - k/a)}{\Gamma(d)}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_singh_maddala(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_singh_maddala.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an Singh-Maddala distribution. The cumulants are calculated from the moments.

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_singh_maddala(mu, sigma).cumulants(k))
6.3563523462564525615615615614561356E+00
```

4.6 Closed form distributions, based on the error function

4.6.1 !!!Boost: Lévy distribution

The following functions return the pdf, cdf, qtf or boost class of the Lévy distribution with location $a \in \mathbb{R}$, scale $b > 0$ and the support interval $(a, +\infty)$.

See also Wikipedia [1186], Ehrhardt [297] (3.9.16).

`math53.levy_pdf`(a, b, x)

Returns pdf(x), the value of the probability density function (*Pdf*) of the Lévy distribution:

$$\text{pdf}(x) = \sqrt{\frac{b}{2\pi}} \frac{e^{-\frac{b}{2(x-a)}}}{(x-a)^{3/2}}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("LevyPdf(x, a, b): ", LevyPdf(x, a, b))
>>> print ("dist_levy(a, b).pdf(x): ", dist_levy(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.levy_cdf`(a, b, x)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the Lévy distribution:

$$\text{cdf}(x) = \text{erfc}\left(\sqrt{\frac{b}{2(x-a)}}\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("LevyCdf(x, a, b): ", LevyCdf(x, a, b))
>>> print ("dist_levy(a, b).cdf(x): ", dist_levy(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.levy_qtf`(a, b, q)

Returns qtf(q), the value of the quantile function (*Qtf*) of the Lévy distribution:

$$\text{qtf}(q) = a + \frac{b}{2(\text{erfc}^{-1}(q))^2}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("LevyQtf(q, a, b): ", LevyQtf(q, a, b))
>>> print ("dist_levy(a, b).qtf(q): ", dist_levy(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class `ctx.dist_levy`(a, b)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The Lévy distribution is a continuous probability distribution with location $a \in \mathbb{R}$, scale $b > 0$ and the support interval $(a, +\infty)$. See also Wikipedia [1186], MathWorld [832].

dist_levy.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a Lévy distribution:

$$\text{pdf}_X(x) = \sqrt{\frac{b}{2\pi}} \frac{e^{-\frac{b}{2(x-a)}}}{(x-a)^{3/2}}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", levy(mu, sigma).pdf(x))
6.356352346256452561561561456135 6E-20
```

dist_levy.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Lévy distribution:

$$\text{cdf}_X(x) = \text{erfc}\left(\sqrt{\frac{b}{2(x-a)}}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", levy(mu, sigma).pdf(x))
6.356352346256452561561561456135 6E-20
```

dist_levy.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function function (sf) of a random variable X, following a Lévy distribution:

$$\text{sf}_X(x) = \text{erf}\left(\sqrt{\frac{b}{2(x-a)}}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", levy(mu, sigma).pdf(x))
sf: 6.356352346256452561561561456135 6E-20
```

dist_levy.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following a Lévy distribution:

$$\text{qtf}_X(q) = a + \frac{b}{2(\text{erfc}^{-1}(q))^2}.$$

where $\text{erfc}(\cdot)$ and $\text{erfc}^{-1}(\cdot)$ denote the complementary error function and its functional inverse, respectively.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", levy(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561456135 6E+00
```

dist_levy.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following a Lévy distribution:

$$\text{isf}_X(q) = a + \frac{b}{2(\text{erf}^{-1}(q))^2}.$$

where $\text{erfc}(\cdot)$ and $\text{erfc}^{-1}(\cdot)$ denote the complementary error function and its functional inverse, respectively.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", levy(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_levy.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Lévy distribution:

$$C_X(t) = e^{i\mu t - \sqrt{-2ict}}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", levy(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_levy.**m_x**(t)

Returns NaN, since the moment generating function does not exist.

dist_levy.**k_x**(t, *k=0*)

Returns NaN, since the cumulant generating function does not exist.

dist_levy.**moments**(k)

Returns NaN, since moments do not exist.

dist_levy.**cumulants**(k)

Returns NaN, since cumulants do not exist.

4.6.2 Boost: Lognormal (Johnson S_L) distribution

The following functions return the pdf, cdf, qtf or boost class of the lognormal distribution with location $a \in \mathbb{R}$, scale $b > 0$, and the support interval $(0, +\infty)$.

See also Wikipedia [1160], MathWorld [829], BoostMath [61], Ehrhardt [297] (3.9.19).

`math53.lognormal_pdf`(a, b, x)

Returns pdf(x), the value of the probability density function (*Pdf*) of the lognormal distribution:

$$\text{pdf}(x) = \frac{1}{bx\sqrt{2\pi}} \exp\left(-\frac{(\log(x) - a)^2}{2b^2}\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("LognormalPdf(x, a, b): ", LognormalPdf(x, a, b))
>>> print ("dist_lognormal(a, b).pdf(x): ", dist_lognormal(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.lognormal_cdf`(a, b, x)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the lognormal distribution:

$$\text{cdf}(x) = \frac{1}{2}\text{erfc}\left(-\frac{\log(x) - a}{b\sqrt{2}}\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("LognormalCdf(x, a, b): ", LognormalCdf(x, a, b))
>>> print ("dist_lognormal(a, b).cdf(x): ", dist_lognormal(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.lognormal_qtf`(a, b, q)

Returns qtf(q), the value of the quantile function (*Qtf*) of the lognormal distribution:

$$\text{qtf}(q) = \exp\left(a - b\sqrt{2} \cdot \text{erfc}^{-1}(2q)\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("LognormalQtf(q, a, b): ", LognormalQtf(q, a, b))
>>> print ("dist_lognormal(a, b).qtf(q): ", dist_lognormal(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class `ctx.dist_lognormal`(a, b)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The lognormal distribution is a continuous probability distribution with location $a \in \mathbb{R}$, scale $b > 0$, and the support interval $(0, +\infty)$. See also Wikipedia [1160], MathWorld [829], BoostMath [61], Witkovský [1474], R (Statistical System) [526].

dist_lognormal.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an lognormal distribution:

$$\text{pdf}_X(x) = \frac{1}{bx\sqrt{2\pi}} \exp\left(-\frac{(\log(x)-a)^2}{2b^2}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", lognormal(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_lognormal.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an lognormal distribution:

$$\text{cdf}_X(x) = \frac{1}{2}\text{erfc}\left(-\frac{\log(x)-a}{b\sqrt{2}}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", lognormal(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_lognormal.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following an lognormal distribution:

$$\text{sf}_X(x) = \frac{1}{2}\text{erfc}\left(\frac{\log(x)-a}{b\sqrt{2}}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", lognormal(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_lognormal.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following an lognormal distribution:

$$\text{qtf}_X(q) = \exp\left(a - b\sqrt{2}\cdot\text{erfc}^{-1}(2q)\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", lognormal(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_lognormal.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following an lognormal distribution:

$$\text{isf}_X(q) = \exp\left(a + b\sqrt{2} \cdot \text{erfc}^{-1}(2q)\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", lognormal(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_lognormal.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an lognormal distribution. The characteristic function is defined for real values of t, but is not defined for any complex value of t that has a negative imaginary part, and hence the characteristic function is not analytic at the origin. Consequently, the characteristic function of the log-normal distribution cannot be represented as an infinite convergent series. A closed-form formula for the characteristic function in the domain of convergence is not known. A relatively simple approximating formula is available in closed form, and is given by

$$C_X(t) = \frac{\exp(-\frac{V^2+2V}{2\sigma^2})}{\sqrt{1+V}}, \quad \text{where } V = W(-it\sigma^2 e^{\mu}).$$

where W is the Lambert W function. This approximation is derived via an asymptotic method, but it stays sharp all over the domain of convergence.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", lognormal(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_lognormal.**m_x**(t)

The moment generating function does not exist.

dist_lognormal.**k_x**(t, *k=0*)

The cumulant generating function does not exist.

dist_lognormal.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an lognormal distribution. All moments of the log-normal distribution exist.

$$\mu'_X(r) = \exp(r\mu + r^2\sigma^2/2).$$

However, the log-normal distribution is not determined by its moments. This implies that it cannot have a defined moment generating function in a neighborhood of zero.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", lognormal(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_lognormal.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an lognormal distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", lognormal(mu, sigma).cumulants(k))
6.356352346256452561561561561456 1356E+00
```

4.6.3 !!!Boost: Moyal Distribution

The following functions return the pdf, cdf, qtf or boost class of the Moyal distribution with location $a \in \mathbb{R}$, scale $b > 0$, and the support interval $(-\infty, +\infty)$.

See also MathWorld [253], G. [341], Walck [792], Ehrhardt [297] (3.9.21).

`math53.moyal_pdf`(a, b, x)

Returns pdf(x), the value of the probability density function (*Pdf*) of the Moyal distribution:

$$\text{pdf}(x) = \frac{1}{\sqrt{2\pi}b} \exp\left(-\frac{x-a}{2b} - \frac{1}{2}e^{-\frac{x-a}{b}}\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("MoyalPdf(x, a, b): ", MoyalPdf(x, a, b))
>>> print ("dist_moyal(a, b).pdf(x): ", dist_moyal(a, b).pdf(x))
6.356352346256452561561561561456135 6E+00
```

`math53.moyal_cdf`(a, b, x)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the Moyal distribution:

$$\text{cdf}(x) = 1 - P\left(\frac{1}{2}, \frac{e^{-x}}{2}\right) = \text{erfc}\left(\frac{e^{-\frac{x-a}{2b}}}{\sqrt{2}}\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("MoyalCdf(x, a, b): ", MoyalCdf(x, a, b))
>>> print ("dist_moyal(a, b).cdf(x): ", dist_moyal(a, b).cdf(x))
6.356352346256452561561561561456135 6E+00
```

`math53.moyal_qtf`(a, b, q)

Returns qtf(q), the value of the quantile function (*Qtf*) of the Moyal distribution:

$$\text{qtf}(q) = a - b\log\left(2(\text{erfc}^{-1}(q))^2\right)$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("MoyalQtf(q, a, b): ", MoyalQtf(q, a, b))
>>> print ("dist_moyal(a, b).qtf(q): ", dist_moyal(a, b).qtf(q))
6.356352346256452561561561561456135 6E+00
```

class `ctx.dist_moyal`(a, b)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The Moyal distribution is a continuous probability distribution with location $a \in \mathbb{R}$, scale $b > 0$, and the support interval $(-\infty, +\infty)$. See also MathWorld [253], G. [341], Walck [792].

Other References: Amath: inversion, Walck: moments and char func.

dist_moyal.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Moyal distribution:

$$\text{pdf}_X(x) = \frac{1}{\sqrt{2\pi}b} \exp\left(-\frac{x-a}{2b} - \frac{1}{2}e^{-\frac{x-a}{b}}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", moyal(mu, sigma).pdf(x))
6.356352346256452561561561561456135 6E-20
```

dist_moyal.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Moyal distribution:

$$\text{cdf}_X(x) = 1 - P\left(\frac{1}{2}, \frac{e^{-x}}{2}\right) = \text{erfc}\left(\frac{e^{-\frac{x-a}{2b}}}{\sqrt{2}}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", moyal(mu, sigma).pdf(x))
6.356352346256452561561561561456135 6E-20
```

dist_moyal.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function function (sf) of a random variable X, following an Moyal distribution:

$$\text{sf}_X(x) = P\left(\frac{1}{2}, \frac{e^{-x}}{2}\right) = \text{erf}\left(\frac{e^{-\frac{x-a}{2b}}}{\sqrt{2}}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", moyal(mu, sigma).pdf(x))
sf: 6.356352346256452561561561561456135 6E-20
```

dist_moyal.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an Moyal distribution:

$$\text{qtf}_X(q) = a - b\log\left(2(\text{erfc}^{-1}(q))^2\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", moyal(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561456135 6E+00
```

dist_moyal.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following an Moyal distribution:

$$\text{isf}_X(q) = a - b \log\left(2(\text{erf}^{-1}(q))^2\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", moyal(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_moyal.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an Moyal distribution:

$$C_X(t) = \frac{2^{it}}{\sqrt{\pi}}\Gamma\left(\tfrac{1}{2} - it\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", moyal(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_moyal.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following an Moyal distribution:

$$M_X(t) = \frac{2^{t}}{\sqrt{\pi}}\Gamma\left(\tfrac{1}{2} - t\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", moyal(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_moyal.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an Moyal distribution:

$$K_X(t) = \log\left[\frac{2^{t}}{\sqrt{\pi}}\Gamma\left(\tfrac{1}{2} - t\right)\right].$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", moyal(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_moyal.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an Moyal distribution. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", moyal(mu, sigma).moments(k))
6.356352346256452561561561561456 1356E+00
```

dist_moyal.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an Moyal distribution. The cumulants are calculated from the moments.

$$\kappa_X(1) = \log(2) + \gamma, \qquad \kappa_X(n) = (n-1)!(2^n - 1)\zeta(n), \quad n \geq 2.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", moyal(mu, sigma).cumulants(k))
6.356352346256452561561561561456 1356E+00
```

4.6.4 Boost: Normal (Johnson S_N) distribution

The following functions return the pdf, cdf, qtf or boost class of the normal distribution with mean $\mu \in \mathbb{R}$, standard deviation $\sigma > 0$, and the support interval $(-\infty, +\infty)$.

See also Wikipedia [1168], MathWorld [835], BoostMath [67], Ehrhardt [297] (3.9.24).

`math53.`**`normal_pdf`**(*mu=0*, *sigma=1*, *x*)

Returns pdf(x), the value of the probability density function (*Pdf*) of the normal distribution:

$$\text{pdf}(x) = \phi(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("NormalPdf(x, a, b): ", NormalPdf(x, a, b))
>>> print ("dist_normal(a, b).pdf(x): ", dist_normal(a, b).pdf(x))
6.35635234625645256156156145614561356E+00
```

`math53.`**`normal_cdf`**(*mu=0*, *sigma=1*, *x*)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the normal distribution:

$$\text{cdf}(x) = \Phi(x) = \frac{1}{2}\text{erfc}\left(-\frac{x-\mu}{\sigma\sqrt{2}}\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("NormalCdf(x, a, b): ", NormalCdf(x, a, b))
>>> print ("dist_normal(a, b).cdf(x): ", dist_normal(a, b).cdf(x))
6.35635234625645256156156145614561356E+00
```

`math53.`**`normal_qtf`**(*mu=0*, *sigma=1*, *q*)

Returns qtf(q), the value of the quantile function (*Qtf*) of the normal distribution:

$$\text{qtf}(q) = \mu - \sigma\sqrt{2} \cdot \text{erfc}^{-1}(2q).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("NormalQtf(q, a, b): ", NormalQtf(q, a, b))
>>> print ("dist_normal(a, b).qtf(q): ", dist_normal(a, b).qtf(q))
6.35635234625645256156156145614561356E+00
```

`class` `ctx.`**`dist_normal`**(*mu*, *sigma*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The normal distribution is a continuous probability distribution with mean $\mu \in \mathbb{R}$, standard deviation $\sigma > 0$, and the support interval $(-\infty, +\infty)$. See also Wikipedia [1168], MathWorld [835], BoostMath [67], R (Statistical System) [527], Mpmath [544], Mpmath [540].

`dist_normal.pdf(`x`)`

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a normal distribution:

$$\text{pdf}_X(x) = \phi(x) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", normal(mu, sigma).pdf(x))
6.356352346256452561561561456135 6E-20
```

`dist_normal.cdf(`x`)`

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a normal distribution:

$$\text{cdf}_X(x) = \Phi(x) = \frac{1}{2}\text{erfc}\left(-\frac{x-\mu}{\sigma\sqrt{2}}\right).$$

Here $\text{erf}(\cdot)$ and $\text{erf}^{-1}(\cdot)$ are the error function and its functional inverse, respectively.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", normal(mu, sigma).pdf(x))
6.356352346256452561561561456135 6E-20
```

`dist_normal.sf(`x`)`

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following a normal distribution:

$$\text{sf}_X(x) = 1 - \Phi(x) = \frac{1}{2}\text{erfc}\left(\frac{x-\mu}{\sigma\sqrt{2}}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", normal(mu, sigma).pdf(x))
sf: 6.356352346256452561561561456135 6E-20
```

`dist_normal.qtf(`q`)`

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a normal distribution:

$$\text{qtf}_X(q) = \mu - \sigma\sqrt{2} \cdot \text{erfc}^{-1}(2q).$$

Here $\text{erf}(\cdot)$ and $\text{erf}^{-1}(\cdot)$ are the error function and its functional inverse, respectively.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", normal(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_normal.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a normal distribution:

$$\text{isf}_X(q) = \mu + \sigma\sqrt{2} \cdot \text{erfc}^{-1}(2q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", normal(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_normal.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a normal distribution:

$$C_X(t) = \exp\left(i\mu t - \tfrac{1}{2}\sigma^2 t^2\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", normal(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_normal.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a normal distribution:

$$M_X(t) = \exp\left(\mu t + \tfrac{1}{2}\sigma^2 t^2\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", normal(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_normal.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(t), j = 1 \ldots k$, of a random variable X, following a normal distribution:

$$K_X(t) = \mu t + \tfrac{1}{2}\sigma^2 t^2,$$

$$K_X^{(1)}(t) = \mu + \sigma^2 t, \quad K_X^{(2)}(t) = \sigma^2, \quad K_X^{(j)}(t) = 0, \quad j > 2.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", normal(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_normal.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \dots k$, of a random variable X, following a normal distribution: the moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", normal(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_normal.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \dots k$, of a random variable X, following a normal distribution:

$$\kappa_1 = \mu, \quad \kappa_2 = \sigma^2, \quad \kappa_j = 0, \quad j > 2.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", normal(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.6.5 Boost: Skew normal Distribution

The following functions return the pdf, cdf, qtf or boost class of the skew normal distribution with location $a \in \mathbb{R}$, scale $b > 0$, shape $c \in \mathbb{R}$, and the support interval $(-\infty, +\infty)$.

See also Wikipedia [1193], MathWorld [256], BoostMath [86], Haas [360].

`math53.skewnormal_pdf`(a, b, c, x)

Returns pdf(x), the value of the probability density function (*Pdf*) of the skew normal distribution:

$$\text{pdf}(x) = \frac{2}{b}\phi\left(\frac{x-a}{b}\right)\Phi\left(c\left(\frac{x-a}{b}\right)\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("SkewnormalPdf(x, a, b): ", SkewnormalPdf(x, a, b))
>>> print ("dist_skewnormal(a, b).pdf(x): ", dist_skewnormal(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.skewnormal_cdf`(a, b, c, x)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the skew normal distribution:

$$\text{cdf}(x) = \Phi\left(\frac{x-a}{b}\right) - 2T\left(\frac{x-a}{b}, c\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("SkewnormalCdf(x, a, b): ", SkewnormalCdf(x, a, b))
>>> print ("dist_skewnormal(a, b).cdf(x): ", dist_skewnormal(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.skewnormal_qtf`(a, b, c, q)

Returns qtf(q), the value of the quantile function (*Qtf*) of the skew normal distribution:

There is no known closed form for qtf(q): it computed with Newton iterations where the starting values are from the corresponding Boost functions (in double precision).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("SkewnormalQtf(q, a, b): ", SkewnormalQtf(q, a, b))
>>> print ("dist_skewnormal(a, b).qtf(q): ", dist_skewnormal(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

`class ctx.dist_skewnormal`(a, b, c)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The skew normal distribution is a continuous probability distribution with location $a \in \mathbb{R}$, scale $b > 0$, shape $c \in \mathbb{R}$, and the support interval $(-\infty, +\infty)$. See also Wikipedia [1193], MathWorld [256], BoostMath [86], Witkovský [1496], Haas [360].

dist_skewnormal.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a skew normal distribution:

$$\text{pdf}_X(x) = \frac{2}{b}\phi\left(\frac{x-a}{b}\right)\Phi\left(c\left(\frac{x-a}{b}\right)\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", mp_skewnormal(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_skewnormal.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a skew normal distribution:

$$\text{cdf}_X(x) = \Phi\left(\frac{x-a}{b}\right) - 2T\left(\frac{x-a}{b}, c\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", mp_skewnormal(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_skewnormal.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function function (sf) of a random variable X, following a skew normal distribution:

$$\text{sf}_X(x) = \Phi\left(-\frac{x-a}{b}\right) + 2T\left(\frac{x-a}{b}, c\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", mp_skewnormal(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_skewnormal.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following a skew normal distribution:

There is no known closed form for $\text{qtf}_X(q)$ or $\text{isf}_X(q)$: These functions are computed with Newton iterations where the starting values are from the corresponding Boost functions (in double precision).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", mp_skewnormal(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_skewnormal.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following a skew normal distribution:

There is no known closed form for $\text{qtf}_X(q)$ or $\text{isf}_X(q)$: These functions are computed with Newton iterations where the starting values are from the corresponding Boost functions (in double precision).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", mp_skewnormal(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_skewnormal.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following a skew normal distribution:

$$C_X(t) = 2\exp\left(ita - \frac{b^2t^2}{2}\right)\Phi(itbd).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_skewnormal(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_skewnormal.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following a skew normal distribution:

$$M_X(t) = 2\exp\left(ta + \frac{b^2t^2}{2}\right)\Phi(tbd).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_skewnormal(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_skewnormal.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a skew normal distribution:

$$K_X(t) = ta + \frac{b^2t^2}{2} + \log\left(2\Phi(tbd)\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", mp_skewnormal(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_skewnormal.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a skew normal distribution:

$$\mu'_{2r+1} = \sqrt{\frac{2}{\pi}}\frac{(2r+1)!}{2^r r!}\sum_{j=0}^{r}(-1)^j\binom{r}{j}\frac{d^{2j+1}}{2j+1}$$

The even moments are equal to those of the standard normal. Hass 2012: Odd Moments

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_skewnormal(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_skewnormal.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a skew normal distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_skewnormal(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.6.6 Boost: Wald (or Inverse Gaussian) distribution

The following functions return the pdf, cdf, qtf or boost class of the Wald distribution with mean $\mu > 0$, scale $b > 0$, and the support interval $(0, +\infty)$.

See also Wikipedia [1157], MathWorld [827], BoostMath [59], Ehrhardt [297] (3.9.32).

`math53.`**`wald_pdf`**(*mu*, *b*, *x*)

Returns pdf(x), the value of the probability density function (*Pdf*) of the Wald distribution:

$$\text{pdf}(x) = \sqrt{\frac{b}{2\pi x^3}} \exp\left(\frac{-b(x-\mu)^2}{2\mu^2 x}\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("WaldPdf(x, a, b): ", WaldPdf(x, a, b))
>>> print ("dist_wald(a, b).pdf(x): ", dist_wald(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`wald_cdf`**(*mu*, *b*, *x*)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the Wald distribution:

$$\text{cdf}(x) = \Phi\left(\sqrt{\frac{b}{x}}\left(\frac{x}{\mu} - 1\right)\right) + \exp\left(\frac{2b}{\mu}\right)\Phi\left(-\sqrt{\frac{b}{x}}\left(\frac{x}{\mu} + 1\right)\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("WaldCdf(x, a, b): ", WaldCdf(x, a, b))
>>> print ("dist_wald(a, b).cdf(x): ", dist_wald(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`wald_qtf`**(*mu*, *b*, *q*)

Returns qtf(q), the value of the quantile function (*Qtf*) of the Wald distribution:

There is no known closed form for qtf(q): it is computed with Newton iterations where the starting values are from the corresponding Boost functions (in double precision).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("WaldQtf(q, a, b): ", WaldQtf(q, a, b))
>>> print ("dist_wald(a, b).qtf(q): ", dist_wald(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

`class` `ctx.`**`dist_wald`**(*mu*, *b*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The Wald (or inverse Gaussian) distribution is a continuous probability distribution with mean $\mu > 0$, scale $b > 0$, and the support interval $(0, +\infty)$. See also Wikipedia [1157], MathWorld [827], BoostMath [59], Witkovský [1472].

dist_wald.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a Wald distribution:

$$\text{pdf}_X(x) = \sqrt{\frac{b}{2\pi x^3}} \exp\left(\frac{-b(x-\mu)^2}{2\mu^2 x}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", wald(mu, sigma).pdf(x))
6.356352346256452561561561561456 1356E-20
```

dist_wald.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Wald distribution:

$$\text{cdf}_X(x) = \Phi\left(\sqrt{\frac{b}{x}}\left(\frac{x}{\mu} - 1\right)\right) + \exp\left(\frac{2b}{\mu}\right)\Phi\left(-\sqrt{\frac{b}{x}}\left(\frac{x}{\mu} + 1\right)\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", wald(mu, sigma).pdf(x))
6.356352346256452561561561561456 1356E-20
```

dist_wald.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following a Wald distribution:

$$\text{sf}_X(x) = \Phi\left(-\sqrt{\frac{b}{x}}\left(\frac{x}{\mu} - 1\right)\right) - \exp\left(\frac{2b}{\mu}\right)\Phi\left(-\sqrt{\frac{b}{x}}\left(\frac{x}{\mu} + 1\right)\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", wald(mu, sigma).pdf(x))
sf: 6.356352346256452561561561561456 1356E-20
```

dist_wald.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Wald distribution:

There is no known closed form for $\text{qtf}_X(q)$ or $\text{isf}_X(q)$: These functions are computed with Newton iterations where the starting values are from the corresponding Boost functions (in double precision).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", wald(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561456 1356E+00
```

dist_wald.**isf**(*q*)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Wald distribution:

There is no known closed form for $\text{qtf}_X(q)$ or $\text{isf}_X(q)$: These functions are computed with Newton iterations where the starting values are from the corresponding Boost functions (in double precision).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", wald(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_wald.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Wald distribution:

$$C_X(t) = \exp\left[\frac{\lambda}{\mu}\left(1 - \sqrt{1 - \frac{2\mu^2 it}{\lambda}}\right)\right].$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", wald(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_wald.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following a Wald distribution:

$$M_X(t) = \exp\left[\frac{\lambda}{\mu}\left(1 - \sqrt{1 - \frac{2\mu^2 t}{\lambda}}\right)\right].$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", wald(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_wald.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(t), j = 1 \ldots k$, of a random variable X, following a Wald distribution:

$$K_X(t) = \frac{\lambda}{\mu}\left(1 - \sqrt{1 - \frac{2\mu^2 t}{\lambda}}\right).$$

$$K_X^{(j)}(t) = tbd.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", wald(mu, sigma).k_x(t, k))
6.3563523462564525615615615614561356E+00
```

dist_wald.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Wald distribution. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", wald(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_wald.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a Wald distribution.

$$\kappa_X(n+1) = \kappa_{X,n+1} = \frac{(2n)!}{2^n n! \mu^{2n+1} \lambda^n}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", wald(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.6.7 Birnbaum-Saunders Distribution

class ctx.**dist_birnb_saunders**(*mu*, *sigma*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The Birnbaum-Saunders distribution is a continuous probability distribution with mean $\mu \in \mathbb{R}$, standard deviation $\sigma > 0$, and the support interval $(-\infty, +\infty)$. See also Wikipedia [1176], MathWorld [246], Balakrishnan and Kundi [25].

dist_birnb_saunders.**pdf**(*x*)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Birnbaum-Saunders distribution:

$$\text{pdf}_X(x) = \frac{1}{2\sqrt{2\pi}\alpha\beta} \left[\sqrt{\frac{t}{\beta}} + \sqrt{\frac{\beta^3}{t^3}} \right] \exp\left[-\frac{1}{2\alpha^2} \left(\frac{t}{\beta} + \frac{\beta}{t} - 2 \right) \right].$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", mp_birnb_saunders(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_birnb_saunders.**cdf**(*x*)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Birnbaum-Saunders distribution:

$$\text{cdf}_X(x) = \Phi\left[\frac{1}{\alpha} \left(\sqrt{\frac{t}{\beta}} - \sqrt{\frac{\beta}{t}} \right) \right].$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", mp_birnb_saunders(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_birnb_saunders.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following an Birnbaum-Saunders distribution:

$$\mathrm{sf}_X(x) = 1 - \Phi\left[\frac{1}{\alpha}\left(\sqrt{\frac{t}{\beta}} - \sqrt{\frac{\beta}{t}}\right)\right].$$

```

```

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", mp_birnb_saunders(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_birnb_saunders.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an Birnbaum-Saunders distribution:

$$\mathrm{qtf}_X(q) = \frac{\beta}{4}\left[\alpha Z + \sqrt{(\alpha Z)^2 + 4}\right]^2, \quad Z = \Phi^{-1}(q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", mp_birnb_saunders(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_birnb_saunders.**isf**(q)

Returns $\mathrm{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following an Birnbaum-Saunders distribution:

$$\mathrm{isf}_X(q) = \frac{\beta}{4}\left[\alpha Z + \sqrt{(\alpha Z)^2 + 4}\right]^2, \quad Z = \Phi^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", mp_birnb_saunders(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_birnb_saunders.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an Birnbaum-Saunders distribution:

$$C_X(t) = \frac{1}{2}\exp\left[\frac{\beta}{\alpha} - \sqrt{\frac{\beta^2}{\alpha^2} - 2it\beta}\right]\left(1 + \sqrt{\frac{1}{1 - 2it\alpha^2/\beta}}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_birnb_saunders(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_birnb_saunders.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following an Birnbaum-Saunders distribution:

$$M_X(t) = \frac{1}{2}\exp\left[\frac{\beta}{\alpha} - \sqrt{\frac{\beta^2}{\alpha^2} - 2t\beta}\right]\left(1 + \sqrt{\frac{1}{1 - 2t\alpha^2/\beta}}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", mp_birnb_saunders(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_birnb_saunders.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an Birnbaum-Saunders distribution:

$$K_X(t) = \frac{\beta}{\alpha} - \sqrt{\frac{\beta^2}{\alpha^2} - 2t\beta} + \log\left(1 + \sqrt{\frac{1}{1 - 2t\alpha^2/\beta}}\right) - \log(2).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", mp_birnb_saunders(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_birnb_saunders.**moments**(*k*)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an Birnbaum-Saunders distribution (Wikipedia). The raw moments are calculated from the central moments.

$$\mu_X(r) = \beta^r \sum_{j=0}^{r} \binom{2r}{2j} \sum_{i=0}^{j} \binom{i}{j} \frac{(2r - 2j + 2i)!}{2^{r-j+i}(r - j + i)!}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_birnb_saunders(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_birnb_saunders.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an Birnbaum-Saunders distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_birnb_saunders(mu, sigma).cumulants(k))
6.356352346256452561561561561456135 6E+00
```

4.6.8 Exponentially Modified Gaussian (EMG) distribution

class ctx.**dist_emg**(*n1*, *n2*, *lambda*, ***kwargs*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

These functions return PDF, CDF, and ICDF of the exponentially modified Gaussian distribution with location a, scale $b > 0$, and the support interval $(-\infty, +\infty)$:

See also: Wikipedia [1203].

dist_emg.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an exponentially modified Gaussian distribution:

$$\mathrm{pdf}_X(x) = f(x;\mu,\sigma,\lambda) = \frac{\lambda}{2} e^{\frac{\lambda}{2}(2\mu+\lambda\sigma^2-2x)} \operatorname{erfc}\left(\frac{\mu+\lambda\sigma^2-x}{\sqrt{2}\sigma}\right)$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", dist_emg(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_emg.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an exponentially modified Gaussian distribution:

$$\mathrm{cdf}_X(x) = \Phi(x,\mu,\sigma) - \tfrac{1}{2} e^{\frac{\lambda}{2}(2\mu+\lambda\sigma^2-2x)} \operatorname{erfc}\left(\frac{\mu+\lambda\sigma^2-x}{\sqrt{2}\sigma}\right)$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", dist_emg(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_emg.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following an exponentially modified Gaussian distribution:

$$\mathrm{sf}_X(x) = \Phi(-x,\mu,\sigma) + \tfrac{1}{2} e^{\frac{\lambda}{2}(2\mu+\lambda\sigma^2-2x)} \operatorname{erfc}\left(\frac{\mu+\lambda\sigma^2-x}{\sqrt{2}\sigma}\right)$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", dist_emg(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_emg.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an exponentially modified Gaussian distribution:

$$\text{qtf}_X(q) = ??$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", dist_emg(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_emg.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following an exponentially modified Gaussian distribution:

$$\text{isf}_X(q) = ??$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", dist_emg(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_emg.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an exponentially modified Gaussian distribution:

$$C_X(t) = \left(1 - \frac{it}{\lambda}\right)^{-1} \exp\left(i\mu t - \tfrac{1}{2}\sigma^2 t^2\right)$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_emg(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_emg.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following an exponentially modified Gaussian distribution:

$$M_X(t) = \left(1 - \frac{t}{\lambda}\right)^{-1} \exp\left(\mu t + \tfrac{1}{2}\sigma^2 t^2\right)$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", dist_emg(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_emg.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an exponentially modified Gaussian distribution:

$$K_X(t) = \log(M_X(t))$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", dist_emg(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_emg.**moments**(*k*)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an exponentially modified Gaussian distribution. The moments are calculated from their definition:

$$\mu'_X(r) = E(X^r) = \int_0^1 x^r \text{pdf}_X(x) \text{d}x$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_emg(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_emg.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an exponentially modified Gaussian distribution. The cumulants are calculated from the moments.

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_emg(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.6.9 Folded normal distribution

class ctx.**dist_folded_normal**(*n1*, *n2*, *lambda*, ***kwargs*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

These functions return PDF, CDF, and ICDF of the folded normal distribution with location a, scale $b > 0$, and the support interval $(-\infty, +\infty)$:

See also: Wikipedia [1205], Tsagris *et al.* [790], Reig *et al.* [476].

dist_folded_normal.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an folded normal distribution:

$$\mathrm{pdf}_X(x) = f_Y(x;\mu,\sigma^2) = \frac{1}{\sqrt{2\pi\sigma^2}}\, e^{-\frac{(x-\mu)^2}{2\sigma^2}} + \frac{1}{\sqrt{2\pi\sigma^2}}\, e^{-\frac{(x+\mu)^2}{2\sigma^2}}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", dist_folded_normal(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_folded_normal.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an folded normal distribution:

$$\mathrm{cdf}_X(x) = F_Y(x;\mu,\sigma^2) = \frac{1}{2}\left[\mathrm{erf}\left(\frac{x+\mu}{\sqrt{2\sigma^2}}\right) + \mathrm{erf}\left(\frac{x-\mu}{\sqrt{2\sigma^2}}\right)\right]$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", dist_folded_normal(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_folded_normal.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following an folded normal distribution:

$$\mathrm{sf}_X(x) = 1 - F_Y(x;\mu,\sigma^2) = 1 - \frac{1}{2}\left[\mathrm{erf}\left(\frac{x+\mu}{\sqrt{2\sigma^2}}\right) + \mathrm{erf}\left(\frac{x-\mu}{\sqrt{2\sigma^2}}\right)\right]$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", dist_folded_normal(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_folded_normal.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an folded normal distribution:

$$\mathrm{qtf}_X(q) = ??$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", dist_folded_normal(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_folded_normal.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following an folded normal distribution:

$$\text{isf}_X(q) = ??$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", dist_folded_normal(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_folded_normal.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an folded normal distribution:

$$C_X(t) = e^{\frac{-\sigma^2 t^2}{2} + i\mu t}\Phi\left(\frac{\mu}{\sigma} + i\sigma t\right) + e^{-\frac{\sigma^2 t^2}{2} - i\mu t}\Phi\left(-\frac{\mu}{\sigma} + i\sigma t\right).$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_folded_normal(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_folded_normal.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following an folded normal distribution:

$$M_X(t) = e^{\frac{\sigma^2 t^2}{2} + \mu t}\Phi\left(\frac{\mu}{\sigma} + \sigma t\right) + e^{\frac{\sigma^2 t^2}{2} - \mu t}\Phi\left(-\frac{\mu}{\sigma} + \sigma t\right).$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", dist_folded_normal(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_folded_normal.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an folded normal distribution:

$$K_X(t) = \left(\frac{\sigma^2 t^2}{2} + \mu t\right) + \log\left\{1 - \Phi\left(-\frac{\mu}{\sigma} - \sigma t\right) + e^{\frac{\sigma^2 t^2}{2} - \mu t}\left[1 - \Phi\left(\frac{\mu}{\sigma} - \sigma t\right)\right]\right\}.$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", dist_folded_normal(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_folded_normal.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an folded normal distribution. The moments are calculated from their definition:

$$\mu'_X(r) = E(X^r) = \int_0^1 x^r \mathrm{pdf}_X(x) \mathrm{d}x$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_folded_normal(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_folded_normal.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an folded normal distribution. The cumulants are calculated from the moments.

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_folded_normal(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.6.10 Half-normal distribution

class ctx.**dist_half_normal**(*sigma*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The half-normal distribution is a continuous probability distribution with standard deviation $\sigma > 0$, and the support interval $(0, +\infty)$. See also Wikipedia [1179], MathWorld [825], Witkovský [1488], .

dist_half_normal.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an half-normal distribution:

$$\mathrm{pdf}_X(x) = \frac{\sqrt{2}}{\sigma\sqrt{\pi}} \exp\left(\frac{x^2}{2\sigma^2}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", half_normal(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_half_normal.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an half-normal distribution:

$$\mathrm{cdf}_X(x) = \mathrm{erf}\left(\frac{x}{\sigma\sqrt{2}}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", half_normal(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_half_normal.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following an half-normal distribution:

$$\mathrm{sf}_X(x) = \mathrm{erfc}\left(\frac{x}{\sigma\sqrt{2}}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", half_normal(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_half_normal.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following an half-normal distribution:

$$\mathrm{qtf}_X(q) = \sigma\sqrt{2} \cdot \mathrm{erf}^{-1}(q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", half_normal(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_half_normal.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following an half-normal distribution:

$$\text{isf}_X(q) = \sigma\sqrt{2} \cdot \text{erfc}^{-1}(q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", half_normal(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_half_normal.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an half-normal distribution:

$$C_X(t) = M\left(\frac{3}{2}, \frac{1}{2}\frac{-t^2}{2}\right) + \frac{2\sqrt{2}\,it}{\sqrt{\pi}} M\left(2, \frac{3}{2}, \frac{-t^2}{2}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", half_normal(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_half_normal.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following an half-normal distribution:

$$M_X(t) = M\left(\frac{3}{2}, \frac{1}{2}\frac{t^2}{2}\right) + \frac{2\sqrt{2}\,t}{\sqrt{\pi}} M\left(2, \frac{3}{2}, \frac{t^2}{2}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", half_normal(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_half_normal.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an half-normal distribution:

$$K_X(t) = \log\left[M\left(\frac{3}{2}, \frac{1}{2}\frac{t^2}{2}\right) + \frac{2\sqrt{2}\,t}{\sqrt{\pi}} M\left(2, \frac{3}{2}, \frac{t^2}{2}\right)\right].$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", half_normal(mu, sigma).k_x(t, k))
6.356352346256452561561561456135 6E+00
```

dist_half_normal.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \dots k$, of a random variable X, following an half-normal distribution (Wikipedia). The raw moments are calculated from the central moments.

$$\mu_X(r) = \begin{cases} \sqrt{\frac{2}{\pi}} k! \alpha^{2k-1} & \text{for } n = 2k-1, \\ (n+1)!! \alpha^n & \text{for } n \text{ even}, \end{cases}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", half_normal(mu, sigma).moments(k))
6.356352346256452561561561456135 6E+00
```

dist_half_normal.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \dots k$, of a random variable X, following an half-normal distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", half_normal(mu, sigma).cumulants(k))
6.356352346256452561561561456135 6E+00
```

4.6.11 Johnson S_B distribution

class ctx.**dist_johnson_sb**(*n1*, *n2*, *lambda*, ***kwargs*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

These functions return PDF, CDF, and ICDF of the Johnson S_B distribution with location a, scale $b > 0$, and the support interval $(-\infty, +\infty)$:

See also: Wikipedia [1215], Jodrá [384], Hill *et al.* [372].

dist_johnson_sb.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Johnson S_B distribution:

$$\mathrm{pdf}_X(x) = f(x;a,b) = \frac{b}{u(1-u)}\phi\left(a + b\log\left(\frac{u}{1-u}\right)\right), \quad \text{where } u = (x-\xi)/\lambda, a = \gamma, b = \delta.$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", dist_johnson_sb(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_johnson_sb.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Johnson S_B distribution:

$$\mathrm{cdf}_X(x) = \Phi\left(a + b\log\left(\frac{x}{1-x}\right)\right), \quad \text{where } u = (x-\xi)/\lambda, a = \gamma, b = \delta$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", dist_johnson_sb(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_johnson_sb.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following an Johnson S_B distribution:

$$\mathrm{sf}_X(x) = \Phi\left(-a - b\log\left(\frac{x}{1-x}\right)\right), \quad \text{where } u = (x-\xi)/\lambda, a = \gamma, b = \delta$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", dist_johnson_sb(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_johnson_sb.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an Johnson S_B distribution:

$$\mathrm{qtf}_X(q) = \lambda\cdot u + \xi, u = \frac{1}{1+\exp\left(-\frac{1}{b}\left(\Phi^{-1}(q) - a\right)\right)}, \quad \text{where } a = \gamma, b = \delta.$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", dist_johnson_sb(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

`dist_johnson_sb.isf(`q`)`

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following an Johnson S_B distribution:

$$\text{isf}_X(q) = \lambda \cdot u + \xi, u = \frac{1}{1 + \exp\left(-\frac{1}{b}\left(\Phi^{-1}(1-q) - a\right)\right)}, \quad \text{where } a = \gamma, b = \delta.$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", dist_johnson_sb(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

`dist_johnson_sb.c_x(`t`)`

Returns $C_X(t)$, the characteristic function of a random variable X, following an Johnson S_B distribution:

$$C_X(t) = \int_0^1 e^{itx} \text{pdf}_X(x) \text{d}x$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_johnson_sb(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

`dist_johnson_sb.m_x(`t`)`

Returns $M_X(t)$, the moment generating function of a random variable X, following an Johnson S_B distribution:

$$M_X(t) = \int_0^1 e^{tx} \text{pdf}_X(x) \text{d}x$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", dist_johnson_sb(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

`dist_johnson_sb.k_x(`t`, k=0)`

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an Johnson S_B distribution:

$$K_X(t) = \log(M_X(t))$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", dist_johnson_sb(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_johnson_sb.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an Johnson S_B distribution. The moments are calculated from their definition:

$$\mu'_X(r) = E(X^r) = \int_0^1 x^r \text{pdf}_X(x) \text{d}x$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_johnson_sb(mu, sigma).moments(k))
6.356352346256452561561561561456 1356E+00
```

dist_johnson_sb.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an Johnson S_B distribution. The cumulants are calculated from the moments.

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_johnson_sb(mu, sigma).cumulants(k))
6.356352346256452561561561561456 1356E+00
```

4.6.12 Johnson S_U distribution

class ctx.**dist_johnson_su**(*n1*, *n2*, *lambda*, ***kwargs*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

These functions return PDF, CDF, and ICDF of the Johnson S_U distribution with location a, scale $b > 0$, and the support interval $(-\infty, +\infty)$:

See also: Wikipedia [1215], Jodrá [384], Hill *et al.* [372].

dist_johnson_su.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Johnson S_U distribution:

$$\mathrm{pdf}_X(x) = \frac{b}{\sqrt{x^2+1}}\phi\left(a + b\log\left(x + \sqrt{x^2+1}\right)\right), \quad \text{where } u = (x-\xi)/\lambda, a = \gamma, b = \delta.$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", dist_johnson_su(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_johnson_su.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Johnson S_U distribution:

$$\mathrm{cdf}_X(x) = \Phi\left(a + b\log\left(x + \sqrt{x^2+1}\right)\right), \quad \text{where } u = (x-\xi)/\lambda, a = \gamma, b = \delta$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", dist_johnson_su(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_johnson_su.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following an Johnson S_U distribution:

$$\mathrm{sf}_X(x) = \Phi\left(-a - b\log\left(x + \sqrt{x^2+1}\right)\right), \quad \text{where } u = (x-\xi)/\lambda, a = \gamma, b = \delta$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", dist_johnson_su(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_johnson_su.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an Johnson S_U distribution:

$$\mathrm{qtf}_X(q) = \sinh\left(\frac{\Phi^{-1}(q) - a}{b}\right), \quad \text{where } u = (x-\xi)/\lambda, a = \gamma, b = \delta$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", dist_johnson_su(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561456 1356E+00
```

`dist_johnson_su.isf(`q`)`

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following an Johnson S_U distribution:

$$\text{isf}_X(q) = \sinh\left(\frac{\Phi^{-1}(1-q) - a}{b}\right), \quad \text{where } u = (x-\xi)/\lambda, a = \gamma, b = \delta$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", dist_johnson_su(mu, sigma).isf(q))
6.356352346256452561561561456 1356E+00
```

`dist_johnson_su.c_x(`t`)`

Returns $C_X(t)$, the characteristic function of a random variable X, following an Johnson S_U distribution:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \text{d}x$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_johnson_su(mu, sigma).c_x(t))
6.356352346256452561561561456 1356E+00
```

`dist_johnson_su.m_x(`t`)`

Returns $M_X(t)$, the moment generating function of a random variable X, following an Johnson S_U distribution:

$$M_X(t) = \int_0^1 e^{tx} \text{pdf}_X(x) \text{d}x$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", dist_johnson_su(mu, sigma).c_x(t))
6.356352346256452561561561456 1356E+00
```

`dist_johnson_su.k_x(`t`, `*`k=0`*`)`

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an Johnson S_U distribution:

$$K_X(t) = \log(M_X(t))$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", dist_johnson_su(mu, sigma).k_x(t, k))
6.356352346256452561561561456 1356E+00
```

dist_johnson_su.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an Johnson S_U distribution (See Johnson1949, page 163)

If r is even:

$$\mu'_r = 2^{-(r-1)} \sum_{s=0}^{\frac{1}{2}r-1} (-1)^s \binom{r}{s} e^{\frac{1}{2}(r-2s)^2\delta^{-2}} \cosh[(r-2s)(\gamma/\delta)] + (-1)^{\frac{1}{2}r} \frac{1}{2} \binom{r}{\frac{1}{2}r}$$

If r is odd:

$$\mu'_r = 2^{-(r-1)} \sum_{s=0}^{\frac{1}{2}r-1} (-1)^{s+1} \binom{r}{s} e^{\frac{1}{2}(r-2s)^2\delta^{-2}} \sinh[(r-2s)(\gamma/\delta)]$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_johnson_su(mu, sigma).moments(k))
6.3563523462564525615615615614561356E+00
```

dist_johnson_su.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an Johnson S_U distribution. The cumulants are calculated from the moments.

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_johnson_su(mu, sigma).cumulants(k))
6.3563523462564525615615615614561356E+00
```

4.6.13 Normal maximum distribution, $\rho_{ij,i\neq j} = 0$

class ctx.**dist_nmax_0**(k)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The normal maximum distribution (the distribution of the maximum of $k \geq 1$ independent standard normal variates) is a continuous probability distribution with the support interval $(-\infty, +\infty)$.

Let $X_1, \ldots, X_k$ be a random sample of size k from a $\mathcal{N}(0, \sigma^2)$ distribution. Let s^2 be an independent mean square estimate of σ with n degrees of freedom. Then

$$Q_1 = \frac{\max X_j}{s}, \quad j = 1, \ldots, k$$

follows a studentized maximum distribution with k and n degrees of freedom, and

$$Q_2 = \frac{\max|X_j|}{s}, \quad j = 1, \ldots, k$$

follows a Studentized Maximum Modulus distribution with k and n degrees of freedom.

See also Stoline and Ury [508], Hochberg and Tamhane [373], Narula [423].

For tables see Bechhofer and Dunnett [26], Stoline and Ury [508], and Hahn and Hendrickson [361].

dist_nmax_0.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a normal maximum distribution:

$$\text{pdf}_X(x) = f_{\text{nmax0}}(x, k) = k \cdot \Phi(x)^{k-1} \cdot \phi(x).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", mp_smm(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_nmax_0.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a normal maximum distribution:

$$\text{cdf}_X(x) = F_{\text{nmax0}}(x, k) = [\Phi(x)]^k.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", mp_smm(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_nmax_0.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function function (sf) of a random variable X, following a normal maximum distribution:

$$\text{sf}_X(x) = 1 - [\Phi(x)]^k.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", mp_smm(mu, sigma).pdf(x))
sf: 6.356352346256452561561561561456135 6E-20
```

`dist_nmax_0.qtf(`q`)`

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following a normal maximum distribution:

$$\text{qtf}_X(x) = \Phi^{-1}\left(q^{1/k}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", mp_smm(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561456135 6E+00
```

`dist_nmax_0.isf(`q`)`

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following a normal maximum distribution:

$$\text{isf}_X(x) = \Phi^{-1}\left((1-q)^{1/k}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", mp_smm(mu, sigma).isf(q))
6.356352346256452561561561561456135 6E+00
```

`dist_nmax_0.c_x(`t`)`

Returns $C_X(t)$, the characteristic function of a random variable X, following a normal maximum distribution:

$$C_X(t) = \int_0^\infty e^{itx}\text{pdf}_X(x)\mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_smm(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

`dist_nmax_0.m_x(`t`)`

Returns $M_X(t)$, the moment generating function of a random variable X, following a normal maximum distribution:

$$M_X(t) = \int_0^\infty e^{tx}\text{pdf}_X(x)\mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_smm(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_nmax_0.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a normal maximum distribution:

$$K_X(t) = \log\left(M_X(t)\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_smm(mu, sigma).c_x(t))
6.35635234625645256156156145613356E+00
```

dist_nmax_0.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a normal maximum distribution. The rth moments only exists for $n_2 > 2r$.

$$\mu'_X(r) = \int_0^\infty x^r \mathrm{pdf}_X(x)\mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_smm(mu, sigma).moments(k))
6.35635234625645256156156145613356E+00
```

dist_nmax_0.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a central Studentized Maximum Modulus distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_smm(mu, sigma).cumulants(k))
6.35635234625645256156156145613356E+00
```

4.6.14 Normal maximum modulus distribution, $\rho_{ij,i\neq j} = 0$

class ctx.**dist_nmm_0**(k)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The normal maximum modulus distribution (the distribution of the maximum of the absolute value of $k \geq 1$ independent standard normal variates) is a continuous probability distribution with the support interval $(0, +\infty)$.

Let $X_1, \ldots, X_k$ be a random sample of size k from a $\mathcal{N}(0, \sigma^2)$ distribution. Let s^2 be an independent mean square estimate of σ with n degrees of freedom. Then

$$Q_1 = \frac{\max X_j}{s}, \quad j = 1, \ldots, k$$

follows a studentized maximum distribution with k and n degrees of freedom, and

$$Q_2 = \frac{\max |X_j|}{s}, \quad j = 1, \ldots, k$$

follows a Studentized Maximum Modulus distribution with k and n degrees of freedom.

See also Stoline and Ury [508], Hochberg and Tamhane [373], Narula [423].

For tables see Bechhofer and Dunnett [26], Stoline and Ury [508], and Hahn and Hendrickson [361].

dist_nmm_0.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a normal maximum modulus distribution:

$$\text{pdf}_X(x) = f_{\text{nmm0}}(x, k) = 2k \cdot (2\Phi(x) - 1)^{k-1} \cdot \phi(x), \quad x > 0.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", mp_smm(mu, sigma).pdf(x))
6.356352346256452561561561456135 6E-20
```

dist_nmm_0.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a normal maximum modulus distribution:

$$\text{cdf}_X(x) = F_{\text{nmm0}}(x, k) = [\Phi(x) - \Phi(-x)]^k = [2\Phi(x) - 1]^k, \quad x > 0.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", mp_smm(mu, sigma).pdf(x))
6.356352346256452561561561456135 6E-20
```

dist_nmm_0.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function function (sf) of a random variable X, following a normal maximum modulus distribution:

$$\text{sf}_X(x) = 1 - [\Phi(x) - \Phi(-x)]^k = 1 - [2\Phi(x) - 1]^k, \quad x > 0.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", mp_smm(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

`dist_nmm_0.qtf`(q)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following a normal maximum modulus distribution:

$$\text{qtf}_X(x) = \Phi^{-1}\left(\tfrac{1}{2} + \tfrac{1}{2}q^{1/k}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", mp_smm(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

`dist_nmm_0.isf`(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following a normal maximum modulus distribution:

$$\text{isf}_X(x) = \Phi^{-1}\left(\tfrac{1}{2} + \tfrac{1}{2}(1-q)^{1/k}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", mp_smm(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

`dist_nmm_0.c_x`(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a normal maximum modulus distribution:

$$C_X(t) = \int_0^\infty e^{itx}\text{pdf}_X(x)\mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_smm(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

`dist_nmm_0.m_x`(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a normal maximum modulus distribution:

$$M_X(t) = \int_0^\infty e^{tx}\text{pdf}_X(x)\mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_smm(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_nmm_0.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a normal maximum modulus distribution:

$$K_X(t) = \log\left(M_X(t)\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_smm(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_nmm_0.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a normal maximum modulus distribution. The rth moments only exists for $n_2 > 2r$.

$$\mu'_X(r) = \int_0^\infty x^r \mathrm{pdf}_X(x)\mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_smm(mu, sigma).moments(k))
6.3563523462564525615615615614561356E+00
```

dist_nmm_0.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a central Studentized Maximum Modulus distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_smm(mu, sigma).cumulants(k))
6.3563523462564525615615615614561356E+00
```

4.6.15 Sinh-arcsinh normal distribution

class ctx.**dist_sasnormal**(a, b)

where ctx is dec, mpm, ipm, fpm, gmp or arb.

The sinh-arcsinh normal distribution distribution is a continuous probability distribution with parameters $a > 0$ and $b > 0$, and the support interval $(0, +\infty)$.

See also: Jones and Faddy [391].

dist_sasnormal.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a sinh-arcsinh normal distribution distribution:

$$\text{pdf}_X(x) = \frac{1}{\sqrt{2\pi}} \frac{\delta C_{\epsilon,\delta}(x)}{\sqrt{1+x^2}} \exp\left(-\tfrac{1}{2} S^2_{\epsilon,\delta}(x)\right), \quad \text{where } S_{\epsilon,\delta}(x) = \sinh\left(\epsilon + \delta \sinh^{-1}(x)\right), \text{and } C_{\epsilon,\delta}(x) = \sqrt{1 + S^2_{\epsilon,\delta}(x)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", fisher_f(mu, sigma).pdf(x))
6.356352346256452561561561561456 1356E-20
```

dist_sasnormal.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a sinh-arcsinh normal distribution distribution:

$$\text{cdf}_X(x) = \Phi\left(S_{\epsilon,\delta}(x)\right), \quad \text{where } S_{\epsilon,\delta}(x) = \sinh\left(\epsilon + \delta \sinh^{-1}(x)\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", fisher_f(mu, sigma).pdf(x))
6.356352346256452561561561561456 1356E-20
```

dist_sasnormal.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following a sinh-arcsinh normal distribution distribution:

$$\text{sf}_X(x) = 1 - \Phi\left(S_{\epsilon,\delta}(x)\right), \quad \text{where } S_{\epsilon,\delta}(x) = \sinh\left(\epsilon + \delta \sinh^{-1}(x)\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_f(mu, sigma).pdf(x))
sf: 6.356352346256452561561561561456 1356E-20
```

dist_sasnormal.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a sinh-arcsinh normal distribution distribution:

$$\text{qtf}_X(q) = S_{-\epsilon/\delta,1/\delta}\left(\Phi^{-1}(q)\right), \quad \text{where } S_{\epsilon,\delta}(x) = \sinh\left(\epsilon + \delta \sinh^{-1}(x)\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_f(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561356E+00
```

dist_sasnormal.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a sinh-arcsinh normal distribution distribution:

$$\text{isf}_X(q) = S_{-\epsilon/\delta,1/\delta}\left(\Phi^{-1}(1-q)\right), \quad \text{where } S_{\epsilon,\delta}(x) = \sinh\left(\epsilon + \delta \sinh^{-1}(x)\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.356352346256452561561561561356E+00
```

dist_sasnormal.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a sinh-arcsinh normal distribution distribution:

$$C_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_f(mu, sigma).c_x(t))
6.356352346256452561561561561356E+00
```

dist_sasnormal.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a sinh-arcsinh normal distribution distribution:

$$M_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_f(mu, sigma).c_x(t))
6.356352346256452561561561561356E+00
```

dist_sasnormal.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a sinh-arcsinh normal distribution distribution:

$$K_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_f(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

`dist_sasnormal.`**`moments`**`(`k`)`

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a sinh-arcsinh normal distribution distribution. All moments exist and are given by

$$\mu'_X(r) = \frac{1}{2^r} \sum_{j=0}^{r} (-1)^j \exp\left((r-2j)(\epsilon/\delta)\right) P_{(r-2j)/\delta}, \quad \text{where } P_q = \frac{e^{1/4}}{\sqrt{8\pi}} \left(K_{(q+1)/2}(1/4) + K_{(q-1)/2}(1/4)\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).moments(k))
6.356352346256452561561561561456 1356E+00
```

`dist_sasnormal.`**`cumulants`**`(`k`)`

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a sinh-arcsinh normal distribution distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).cumulants(k))
6.356352346256452561561561561456 1356E+00
```

4.6.16 Truncated normal distribution

class ctx.**dist_truncated_normal**(*n1*, *n2*, *lambda*, ***kwargs*)

These functions return PDF, CDF, and ICDF of the truncated normal distribution with location a, scale $b > 0$, and the support interval $(-\infty, +\infty)$:

See also: Wikipedia [1221], Orjebin [453], Burkardt [164],

John Burkardt: The Truncated Normal Distribution (has closed form qtf)

dist_truncated_normal.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an truncated normal distribution:

$$\mathrm{pdf}_X(x) = f(x;\mu,\sigma,a,b) = \frac{1}{\sigma}\frac{\phi(\frac{x-\mu}{\sigma})}{\Phi\left(\frac{b-\mu}{\sigma}\right) - \Phi\left(\frac{a-\mu}{\sigma}\right)}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", dist_truncated_normal(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_truncated_normal.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an truncated normal distribution:

$$\mathrm{cdf}_X(x) = \frac{\Phi(\xi) - \Phi(\alpha)}{\Phi(\beta) - \Phi(\alpha)}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", dist_truncated_normal(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_truncated_normal.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following an truncated normal distribution:

$$\mathrm{sf}_X(x) = 1 - \frac{\Phi(\xi) - \Phi(\alpha)}{\Phi(\beta) - \Phi(\alpha)}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", dist_truncated_normal(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_truncated_normal.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an truncated normal distribution:

$$\mathrm{qtf}_X(q) = ??$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", dist_truncated_normal(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_truncated_normal.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following an truncated normal distribution:

$$\text{isf}_X(q) = ??$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", dist_truncated_normal(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_truncated_normal.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an truncated normal distribution:

$$C_X(t) = e^{\mu it - \sigma^2 t^2/2} \cdot \frac{\Phi(\beta - \sigma it) - \Phi(\alpha - \sigma it)}{\Phi(\beta) - \Phi(\alpha)}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_truncated_normal(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_truncated_normal.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following an truncated normal distribution:

$$M_X(t) = e^{\mu t + \sigma^2 t^2/2} \cdot \frac{\Phi(\beta - \sigma t) - \Phi(\alpha - \sigma t)}{\Phi(\beta) - \Phi(\alpha)}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", dist_truncated_normal(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_truncated_normal.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an truncated normal distribution:

$$K_X(t) = \log(M_X(t))$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", dist_truncated_normal(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_truncated_normal.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an truncated normal distribution. The moments are calculated from their definition:

$$\mu'_X(r) = E(X^r) = \int_0^1 x^r \text{pdf}_X(x) \text{d}x$$

A recursive formula for μ_k (based on $\mu_{-1} = 0$ and $\mu_0 = 1$) is:

$$\mu'_X(r) = m_k = (k-1)\sigma^2 m_{k-2} + \mu m_{k-1} - \sigma \frac{b^{k-1}\phi\left(\frac{b-\mu}{\sigma}\right) - a^{k-1}\phi\left(\frac{a-\mu}{\sigma}\right)}{\Phi\left(\frac{b-\mu}{\sigma}\right) - \Phi\left(\frac{a-\mu}{\sigma}\right)}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_truncated_normal(mu, sigma).moments(k))
6.35635234625645256156156145613356E+00
```

dist_truncated_normal.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an truncated normal distribution. The cumulants are calculated from the moments.

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_truncated_normal(mu, sigma).cumulants(k))
6.35635234625645256156156145613356E+00
```

4.7 Closed form distributions, based on the incomplete gamma function

4.7.1 !!!Boost: Chi Distribution

The following functions return the pdf, cdf, qtf or boost class of the chi distribution with $n > 0$ degrees of freedom and the support interval $(0, +\infty)$.

See also Wikipedia [1177], MathWorld [820], Ehrhardt [297] (3.9.5)

`math53.chi_pdf(`n, x`)`

Returns pdf(x), the value of the probability density function (*Pdf*) of the chi distribution:

$$\text{pdf}(x) = 2x \times f_{\chi^2}\left(x^2, n\right).$$

Here $f_{\chi^2}(x, n)$ denotes the probability density function of a random variable following an chi-squared distribution with n degress of freedom.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("ChiPdf(x, a, b): ", ChiPdf(x, a, b))
>>> print ("dist_chi(a, b).pdf(x): ", dist_chi(a, b).pdf(x))
6.356352346256452561561561561456 1356E+00
```

`math53.chi_cdf(`n, x`)`

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the chi distribution:

$$\text{cdf}(x) = P(n/2, x^2/2).$$

Here $P(\cdot)$ denotes the lower regularized incomplete gamma function (*RealGammaP*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("ChiCdf(x, a, b): ", ChiCdf(x, a, b))
>>> print ("dist_chi(a, b).cdf(x): ", dist_chi(a, b).cdf(x))
6.356352346256452561561561561456 1356E+00
```

`math53.chi_qtf(`n, q`)`

Returns qtf(q), the value of the quantile function (*Qtf*) of the chi distribution:

$$\text{qtf}(q) = \sqrt{2P^{-1}(n/2, q)}.$$

Here $P^{-1}(\cdot)$ denotes the inverse of the lower regularized incomplete gamma function (*RealGammaPInv*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("ChiQtf(q, a, b): ", ChiQtf(q, a, b))
>>> print ("dist_chi(a, b).qtf(q): ", dist_chi(a, b).qtf(q))
6.356352346256452561561561561456 1356E+00
```

class ctx.**dist_chi**(n)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The chi distribution is a continuous probability distribution with $n > 0$ degrees of freedom and the support interval $(0, +\infty)$. See also Wikipedia [1177], MathWorld [820], Witkovský [1486].

dist_chi.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an chi distribution:

$$\text{pdf}_X(x) = 2x \times f_{\chi^2}\left(x^2, n\right).$$

Here $f_{\chi^2}(x, n)$ denotes the probability density function of a random variable following an chi-squared distribution with n degress of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", chi(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_chi.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an chi distribution:

$$\text{cdf}_X(x) = P(n/2, x^2/2).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", chi(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_chi.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following an chi distribution:

$$\text{sf}_X(x) = Q(n/2, x^2/2).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", chi(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_chi.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following an chi distribution:

$$\text{qtf}_X(q) = \sqrt{2P^{-1}(n/2, q)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", chi(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_chi.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following an chi distribution:

$$\text{isf}_X(q) = \sqrt{2Q^{-1}(n/2, q)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", chi(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_chi.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an chi distribution:

$$C_X(t) = M\left(\frac{k}{2}, \frac{1}{2}, \frac{-t^2}{2}\right) + it\sqrt{2}\frac{\Gamma\left((k+1)/2\right)}{\Gamma(k/2)} M\left(\frac{k+1}{2}, \frac{3}{2}, \frac{-t^2}{2}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_chi.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following an chi distribution:

$$M_X(t) = M\left(\frac{k}{2}, \frac{1}{2}, \frac{t^2}{2}\right) + t\sqrt{2}\frac{\Gamma\left((k+1)/2\right)}{\Gamma(k/2)} M\left(\frac{k+1}{2}, \frac{3}{2}, \frac{t^2}{2}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", chi(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_chi.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an chi distribution:

$$K_X(t) = \log\left[M\left(\frac{k}{2}, \frac{1}{2}, \frac{t^2}{2}\right) + t\sqrt{2}\frac{\Gamma\left((k+1)/2\right)}{\Gamma(k/2)} M\left(\frac{k+1}{2}, \frac{3}{2}, \frac{t^2}{2}\right)\right].$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", chi(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_chi.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an chi distribution (Wikipedia). The raw moments are calculated from the central moments.

$$\mu_X(j) = 2^{2j} \frac{\Gamma\left((k+j)/2\right)}{\Gamma(k/2)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", chi(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_chi.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an chi distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", chi(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.7.2 Boost: Chi2 distribution

The following functions return the pdf, cdf, qtf or boost class of the chi-squared distribution with $n > 0$ degrees of freedom and the support interval $(0, +\infty)$.

See also Wikipedia [1150], MathWorld [798], BoostMath [53], Ehrhardt [297] (3.9.6)

`math53.chi2_pdf(`n, x`)`

Returns pdf(x), the value of the probability density function (*Pdf*) of the chi-squared distribution:

$$\text{pdf}(x) = f_{\chi^2}(x, n) = \frac{1}{2^{n/2}\Gamma(n/2)} x^{(n-2)/2} e^{-x/2}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("ChiSquaredPdf(x, a, b): ", ChiSquaredPdf(x, a, b))
>>> print ("dist_chi_squared(a, b).pdf(x): ", dist_chi_squared(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.chi2_cdf(`n, x`)`

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the chi-squared distribution:

$$\text{cdf}(x) = F_{\chi^2}(x, n) = P(n/2, x/2).$$

Here $P(\cdot)$ denotes the lower regularized incomplete gamma function (*RealGammaP*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("ChiSquaredCdf(x, a, b): ", ChiSquaredCdf(x, a, b))
>>> print ("dist_chi_squared(a, b).cdf(x): ", dist_chi_squared(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.chi2_qtf(`n, q`)`

Returns qtf(q), the value of the quantile function (*Qtf*) of the chi-squared distribution:

$$\text{qtf}(q) = 2P^{-1}(n/2, q).$$

Here $P^{-1}(\cdot)$ denotes the inverse of the lower regularized incomplete gamma function (*RealGammaPInv*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("ChiSquaredQtf(q, a, b): ", ChiSquaredQtf(q, a, b))
>>> print ("dist_chi_squared(a, b).qtf(q): ", dist_chi_squared(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class `ctx.dist_chi2(`n`)`

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The chi-squared distribution is a continuous probability distribution with $n > 0$ degrees of freedom and the support interval $(0, +\infty)$. See also Wikipedia [1150], MathWorld [798], BoostMath [53], Witkovský [1466], R (Statistical System) [522].

dist_chi_squared.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a chi-squared distribution:

$$\text{pdf}_X(x) = f_{\chi^2}(n, x) = \frac{1}{2^{n/2}\Gamma(n/2)} x^{(n-2)/2} e^{-x/2}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", chi_squared(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_chi_squared.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a chi-squared distribution:

$$\text{cdf}_X(x) = F_{\chi^2}(x, n) = P(n/2, x/2).$$

Here $P(\cdot)$ and $P^{-1}(\cdot)$ are the regularized gamma function and its functional inverse, respectively.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", chi_squared(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_chi_squared.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following a chi-squared distribution:

$$\text{sf}_X(x) = 1 - F_{\chi^2}(x, n) = Q(n/2, x/2).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", chi_squared(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_chi_squared.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a chi-squared distribution:

$$\text{qtf}_X(q) = 2P^{-1}(n/2, q).$$

Here $P(\cdot)$ and $P^{-1}(\cdot)$ are the regularized gamma function and its functional inverse, respectively.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", chi_squared(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_chi_squared.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a chi-squared distribution:

$$\text{isf}_X(q) = 2Q^{-1}(n/2, q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", chi_squared(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_chi_squared.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a chi-squared distribution:

$$C_X(t) = (1 - 2it)^{-n/2}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_chi_squared.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a chi-squared distribution:

$$M_X(t) = (1 - 2t)^{-n/2}, \quad t \in \left(-\infty, \tfrac{1}{2}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_chi_squared.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(t), j = 1 \ldots k$, of a random variable X, following a chi-squared distribution:

$$K_X(t) = -\frac{n}{2}\log(1 - 2t), \quad t \in \left(-\infty, \tfrac{1}{2}\right),$$

$$K_X^{(j)}(t) = \frac{2^{j-1}(j-1)!}{(1-2t)^j}n.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", chi_squared(mu, sigma).k_x(t, k))
6.3563523462564525615615615614561356E+00
```

dist_chi_squared.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a chi-squared distribution: the moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", chi_squared(mu, sigma).moments(k))
6.35635234625645256156156145614561356E+00
```

dist_chi_squared.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a chi-squared distribution:

$$\kappa_{r+1} = 2^r r! n.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", chi_squared(mu, sigma).cumulants(k))
6.35635234625645256156156145614561356E+00
```

Recurrences: Central Chi-square

ctx.**chi_squared_recurrence**(x, n, *lambda*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The following recurrence relations hold for the pdf and CDF:

$$f_{\chi^2}(n+2, x) = \frac{x}{n} f_{\chi^2}(n, x)$$

$$F_{\chi^2}(n, x) - F_{\chi^2}(n+2, x) = 2 f_{\chi^2}(n+2, x)$$

Approximations

ctx.**chi_squared_gp**(x, n, *results='cdf'*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

Calculates the pdf, cdf and sf from the characteristic function using the procedure of Gil-Pelaez (see *gil_pelaez_pdf()* and *gil_pelaez_cdf()*).

ctx.**chi_squared_ecf**(x, f, *results='cdf'*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Edgeworth approximation to the pdf, cdf and sf.

ctx.**chi_squared_ecf_inv**(q, f, *results='qtf'*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Cornish-Fisher approximation to the qtf and isf.

ctx.**chi_squared_spa**(x, n, *results='c'*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

Calculates the Luggannini-Rice saddlepoint approximation of the pdf, cdf and sf.

The solution $\hat{s}(x)$ of the saddlepoint equation $K_X^{(1)}(\hat{s}(x)) = x$, of a random variable X, following a non-central chi-squared distribution is given by:

$$\hat{s}(x) = -\frac{1}{4x}\left[n - 2x + n\right], \quad x > 0$$

ctx.**chi_squared_spa_inv**(*x*, *n*, *results='qtf'*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

4.7.3 Boost: Gamma (Pearson Type III, Erlang) distribution

The following functions return the pdf, cdf, qtf or boost class of the gamma distribution with shape $a > 0$, scale $b > 0$, and the support interval $(0, +\infty)$.

See also Wikipedia [1154], MathWorld [822], BoostMath [57], Ehrhardt [297] (3.9.10).

`math53.gamma_pdf`(a, b, x)

Returns pdf(x), the value of the probability density function (*Pdf*) of the gamma distribution:

$$\text{pdf}(x) = \frac{x^{a-1}e^{-x/b}}{\Gamma(a)b^a}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("GammaPdf(x, a, b): ", GammaPdf(x, a, b))
>>> print ("dist_gamma(a, b).pdf(x): ", dist_gamma(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.gamma_cdf`(a, b, x)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the gamma distribution:

$$\text{cdf}(x) = P(a, x/b).$$

Here $P(\cdot)$ denotes the lower regularized incomplete gamma function (*RealGammaP*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("GammaCdf(x, a, b): ", GammaCdf(x, a, b))
>>> print ("dist_gamma(a, b).cdf(x): ", dist_gamma(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.gamma_qtf`(a, b, q)

Returns qtf(q), the value of the quantile function (*Qtf*) of the gamma distribution:

$$\text{qtf}(q) = b \cdot P^{-1}(a, q).$$

Here $P^{-1}(\cdot)$ denotes the inverse of the lower regularized incomplete gamma function (*RealGammaPInv*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("GammaQtf(q, a, b): ", GammaQtf(q, a, b))
>>> print ("dist_gamma(a, b).qtf(q): ", dist_gamma(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class ctx.**dist_gamma**(a, b)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The gamma distribution is a continuous probability distribution with shape $a > 0$, scale $b > 0$, and the support interval $(0, +\infty)$. See also Wikipedia [1154], MathWorld [822], BoostMath [57], Witkovský [1469], R (Statistical System) [525].

See also: https://docs.scipy.org/doc/scipy/reference/generated/scipy.special.gdtrix.html#scipy.special.gdtrix

dist_gamma.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a gamma distribution:

$$\text{pdf}_X(x) = \frac{x^{a-1}e^{-x/b}}{\Gamma(a)b^a}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", gamma(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_gamma.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a gamma distribution:

$$\text{cdf}_X(x) = P(a, x/b).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", gamma(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_gamma.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following a gamma distribution:

$$\text{sf}_X(x) = Q(a, x/b).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", gamma(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_gamma.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a gamma distribution:

$$\text{qtf}_X(q) = b \cdot P^{-1}(a, q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", gamma(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145614356E+00
```

`dist_gamma.isf(`q`)`

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a gamma distribution:

$$\text{isf}_X(q) = b \cdot Q^{-1}(a, q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", gamma(mu, sigma).isf(q))
6.35635234625645256156156145614356E+00
```

`dist_gamma.c_x(`t`)`

Returns $C_X(t)$, the characteristic function of a random variable X, following a gamma distribution:

$$C_X(t) = \left(\frac{b^{-1}}{(b^{-1} - it)}\right)^a.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", gamma(mu, sigma).c_x(t))
6.35635234625645256156156145614356E+00
```

`dist_gamma.m_x(`t`)`

Returns $M_X(t)$, the moment generating function of a random variable X, following a gamma distribution:

$$M_X(t) = \left(\frac{b^{-1}}{(b^{-1} - t)}\right)^a.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", gamma(mu, sigma).c_x(t))
6.35635234625645256156156145614356E+00
```

`dist_gamma.k_x(`t`, k=0)`

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a gamma distribution:

$$K_X(t) = a \log\left(\frac{b^{-1}}{(b^{-1} - t)}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", gamma(mu, sigma).k_x(t, k))
6.35635234625645256156156145614356E+00
```

dist_gamma.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an exponential distribution. The rth moments only exists for $n_2 > 2r$.

$$\mu'_X(r) = b^r \frac{\Gamma(a+r)}{\Gamma(a)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", gamma(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_gamma.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an exponential distribution. The cumulants are calculated from the moments.

$$\kappa'_X(r) = a \cdot b \cdot \Gamma(r).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", gamma(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.7.4 Boost: Inverse chisquared distribution

Returns the pdf, cdf, qtf or boost class of a random variable X, following an inverse chi-squared distribution with shape $a > 0$, scale $b > 0$, and the support interval $(0, +\infty)$.

See also Wikipedia [1158], BoostMath [58], Witkovský [1461].

`math53.`**`inverse_chi2_pdf`**(a, b, x)

Returns $\text{pdf}(x)$, the value of the probability density function (*Pdf*) of the inverse chis-quared distribution:

$$\text{pdf}(x) = \left(\frac{b}{x}\right)^a \frac{e^{-\frac{b}{x}}}{x\Gamma(a)}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("InvchisquaredPdf(x, a, b): ", InvchisquaredPdf(x, a, b))
>>> print ("dist_invchisquared(a, b).pdf(x): ", dist_invchisquared(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`inverse_chi2_cdf`**(a, b, x)

Returns $\text{cdf}(x)$, the value of the cumulative distribution function (*Cdf*) of the inverse chis-quared distribution:

$$\text{cdf}(x) = Q\left(a, -\frac{b}{x}\right).$$

Here $Q(\cdot)$ denotes the upper regularized incomplete gamma function (*RealGammaQ*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("InvchisquaredCdf(x, a, b): ", InvchisquaredCdf(x, a, b))
>>> print ("dist_invchisquared(a, b).cdf(x): ", dist_invchisquared(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`inverse_chi2_qtf`**(a, b, q)

Returns $\text{qtf}(q)$, the value of the quantile function (*Qtf*) of the inverse chis-quared distribution:

$$\text{qtf}(q) = \frac{b}{Q^{-1}(a, q)}.$$

Here $Q^{-1}(\cdot)$ denotes the inverse of the upper regularized incomplete gamma function (*RealGammaQInv*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("InvchisquaredQtf(q, a, b): ", InvchisquaredQtf(q, a, b))
>>> print ("dist_invchisquared(a, b).qtf(q): ", dist_invchisquared(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class ctx.**dist_inverse_chi2**(a, b)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The inverse chisquared distribution is a continuous probability distribution with shape $a > 0$, scale $b > 0$, and the support interval $(0, +\infty)$. See also Wikipedia [1182], MathWorld [251], BoostMath [82].

dist_invchisquared.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an inverse chisquared distribution:

$$\text{pdf}_X(x) = \left(\frac{b}{x}\right)^a \frac{e^{-\frac{b}{x}}}{x\Gamma(a)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", mp_invchisquared(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_invchisquared.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an inverse chisquared distribution:

$$\text{cdf}_X(x) = Q\left(a, -\frac{b}{x}\right).$$

where $Q(\cdot)$ and $Q^{-1}(\cdot)$ denote the regularized gamma function and its functional inverse.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", mp_invchisquared(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_invchisquared.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function function (sf) of a random variable X, following an inverse chisquared distribution:

$$\text{sf}_X(x) = P\left(a, -\frac{b}{x}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", mp_invchisquared(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_invchisquared.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an inverse chisquared distribution:

$$\text{qtf}_X(q) = \frac{b}{Q^{-1}(a, q)}.$$

where $Q(\cdot)$ and $Q^{-1}(\cdot)$ denote the regularized gamma function and its functional inverse.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", mp_invchisquared(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561456 1356E+00
```

dist_invchisquared.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following an inverse chisquared distribution:

$$\text{isf}_X(q) = \frac{b}{P^{-1}(a,q)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", mp_invchisquared(mu, sigma).isf(q))
6.356352346256452561561561561456 1356E+00
```

dist_invchisquared.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an inverse chisquared distribution:

$$C_X(t) = \frac{2(-i\beta t)^{\alpha/2}}{\Gamma(\alpha)} K_\alpha(\sqrt{-4i\beta t}),$$

where $K_n(\cdot)$ denotes the modified Bessel function of the second kind.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_invchisquared(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

dist_invchisquared.**m_x**(t)

The moment generating function does not exist.

dist_invchisquared.**k_x**(t, *k=0*)

The cumulant generating function does not exist.

dist_invchisquared.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an inverse chisquared distribution. The rth moments only exists for $\alpha > r$.

$$\mu'_X(r) = \frac{\beta^n}{(\alpha-1)\cdots(\alpha-n)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_invchisquared(mu, sigma).moments(k))
6.356352346256452561561561561456 1356E+00
```

dist_invchisquared.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an inverse chisquared distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_invchisquared(mu, sigma).cumulants(k))
6.35635234625645256156156145561356E+00
```

4.7.5 Boost: Inverse Gamma (Pearson Type V) distribution

Returns the pdf, cdf, qtf or boost class of a random variable X, following an inverse gamma distribution with shape $a > 0$, scale $b > 0$, and the support interval $(0, +\infty)$.

See also Wikipedia [1158], BoostMath [58], Witkovský [1461], Ehrhardt [297] (3.9.12).

`math53.inverse_gamma_pdf`(a, b, x)

Returns $\text{pdf}(x)$, the value of the probability density function (*Pdf*) of the inverse gamma distribution:

$$\text{pdf}(x) = \left(\frac{b}{x}\right)^a \frac{e^{-\frac{b}{x}}}{x\Gamma(a)}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("InvgammaPdf(x, a, b): ", InvgammaPdf(x, a, b))
>>> print ("dist_invgamma(a, b).pdf(x): ", dist_invgamma(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.inverse_gamma_cdf`(a, b, x)

Returns $\text{cdf}(x)$, the value of the cumulative distribution function (*Cdf*) of the inverse gamma distribution:

$$\text{cdf}(x) = Q\left(a, -\frac{b}{x}\right).$$

Here $Q(\cdot)$ denotes the upper regularized incomplete gamma function (*RealGammaQ*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("InvgammaCdf(x, a, b): ", InvgammaCdf(x, a, b))
>>> print ("dist_invgamma(a, b).cdf(x): ", dist_invgamma(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.inverse_gamma_qtf`(a, b, q)

Returns $\text{qtf}(q)$, the value of the quantile function (*Qtf*) of the inverse gamma distribution:

$$\text{qtf}(q) = \frac{b}{Q^{-1}(a, q)}.$$

Here $Q^{-1}(\cdot)$ denotes the inverse of the upper regularized incomplete gamma function (*RealGammaQInv*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("InvgammaQtf(q, a, b): ", InvgammaQtf(q, a, b))
>>> print ("dist_invgamma(a, b).qtf(q): ", dist_invgamma(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class ctx.**dist_inverse_gamma**(a, b)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The inverse gamma distribution is a continuous probability distribution with shape $a > 0$, scale $b > 0$, and the support interval $(0, +\infty)$. See also Wikipedia [1158], MathWorld [244], BoostMath [58], Witkovský [1471], Witkovský [1461].

dist_invgamma.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an inverse gamma distribution:

$$\text{pdf}_X(x) = \left(\frac{b}{x}\right)^a \frac{e^{-\frac{b}{x}}}{x\Gamma(a)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", invgamma(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_invgamma.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an inverse gamma distribution:

$$\text{cdf}_X(x) = Q\left(a, -\frac{b}{x}\right).$$

where $Q(\cdot)$ and $Q^{-1}(\cdot)$ denote the regularized gamma function and its functional inverse.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", invgamma(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_invgamma.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following an inverse gamma distribution:

$$\text{sf}_X(x) = P\left(a, -\frac{b}{x}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", invgamma(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_invgamma.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following an inverse gamma distribution:

$$\text{qtf}_X(q) = \frac{b}{Q^{-1}(a, q)}.$$

where $Q(\cdot)$ and $Q^{-1}(\cdot)$ denote the regularized gamma function and its functional inverse.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", invgamma(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561456 1356E+00
```

dist_invgamma.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following an inverse gamma distribution:

$$\text{isf}_X(q) = \frac{b}{P^{-1}(a, q)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", invgamma(mu, sigma).isf(q))
6.356352346256452561561561561456 1356E+00
```

dist_invgamma.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an inverse gamma distribution:

$$C_X(t) = \frac{2(-i\beta t)^{\alpha/2}}{\Gamma(\alpha)} K_\alpha(\sqrt{-4i\beta t}),$$

where $K_n(\cdot)$ denotes the modified Bessel function of the second kind.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", invgamma(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

dist_invgamma.**m_x**(t)

The moment generating function does not exist.

dist_invgamma.**k_x**(t, *k=0*)

The cumulant generating function does not exist.

dist_invgamma.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \dots k$, of a random variable X, following an inverse gamma distribution. The rth moments only exists for $\alpha > r$.

$$\mu'_X(r) = \frac{\beta^n}{(\alpha - 1) \cdots (\alpha - n)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", invgamma(mu, sigma).moments(k))
6.356352346256452561561561561456 1356E+00
```

dist_invgamma.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an inverse gamma distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", invgamma(mu, sigma).cumulants(k))
6.356352346256452561561561561456 1356E+00
```

4.7.6 !!!Boost: Maxwell Distribution

Returns the pdf, cdf, qtf or boost class of a random variable X, following a Maxwell distribution with scale $b > 0$, and the support interval $(0, +\infty)$.

See also Wikipedia [1188], MathWorld [833], Ehrhardt [297] (3.9.20).

math53.**maxwell_pdf**(b, x)

Returns pdf(x), the value of the probability density function (*Pdf*) of the Maxwell distribution:

$$\text{pdf}(x) = \sqrt{\frac{2}{\pi}} \frac{x^2}{b^3} \exp\left(-\frac{x^2}{2b^2}\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("MaxwellPdf(x, a, b): ", MaxwellPdf(x, a, b))
>>> print ("dist_maxwell(a, b).pdf(x): ", dist_maxwell(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

math53.**maxwell_cdf**(b, x)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the Maxwell distribution:

$$\text{cdf}(x) = P\left(\frac{3}{2}, \frac{x^2}{2b^2}\right).$$

Here $P(\cdot)$ denotes the lower regularized incomplete gamma function (*RealGammaP*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("MaxwellCdf(x, a, b): ", MaxwellCdf(x, a, b))
>>> print ("dist_maxwell(a, b).cdf(x): ", dist_maxwell(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

math53.**maxwell_qtf**(b, q)

Returns qtf(q), the value of the quantile function (*Qtf*) of the Maxwell distribution:

$$\text{qtf}(q) = b\sqrt{2P^{-1}\left(\frac{3}{2}, q\right)}.$$

Here $P^{-1}(\cdot)$ denotes the inverse of the lower regularized incomplete gamma function (*RealGammaPInv*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("MaxwellQtf(q, a, b): ", MaxwellQtf(q, a, b))
>>> print ("dist_maxwell(a, b).qtf(q): ", dist_maxwell(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class ctx.**dist_maxwell**(b)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The Maxwell distribution is a continuous probability distribution with scale $b > 0$, and the support interval $(0, +\infty)$. See also Wikipedia [1188], MathWorld [833], Witkovský [1489].

dist_maxwell.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Maxwell distribution:

$$\text{pdf}_X(x) = \sqrt{\frac{2}{\pi}} \frac{x^2}{b^3} \exp\left(-\frac{x^2}{2b^2}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", maxwell(mu, sigma).pdf(x))
6.356352346256452561561561561456135 6E-20
```

dist_maxwell.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Maxwell distribution:

$$\text{cdf}_X(x) = P\left(\frac{3}{2}, \frac{x^2}{2b^2}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", maxwell(mu, sigma).pdf(x))
6.356352346256452561561561561456135 6E-20
```

dist_maxwell.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following an Maxwell distribution:

$$\text{sf}_X(x) = Q\left(\frac{3}{2}, \frac{x^2}{2b^2}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", maxwell(mu, sigma).pdf(x))
sf: 6.356352346256452561561561561456135 6E-20
```

dist_maxwell.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following an Maxwell distribution:

$$\text{qtf}_X(q) = b\sqrt{2P^{-1}\left(\frac{3}{2}, q\right)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", maxwell(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145614561356E+00
```

dist_maxwell.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following an Maxwell distribution:

$$\text{isf}_X(q) = b\sqrt{2Q^{-1}\left(\frac{3}{2}, q\right)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", maxwell(mu, sigma).isf(q))
6.35635234625645256156156145614561356E+00
```

dist_maxwell.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an Maxwell distribution:

$$C_X(t) = M\left(\frac{3}{2}, \frac{1}{2}\frac{-t^2}{2}\right) + \frac{2\sqrt{2}\,it}{\sqrt{\pi}} M\left(2, \frac{3}{2}, \frac{-t^2}{2}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", maxwell(mu, sigma).c_x(t))
6.35635234625645256156156145614561356E+00
```

dist_maxwell.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following an Maxwell distribution:

$$M_X(t) = M\left(\frac{3}{2}, \frac{1}{2}\frac{t^2}{2}\right) + \frac{2\sqrt{2}\,t}{\sqrt{\pi}} M\left(2, \frac{3}{2}, \frac{t^2}{2}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", maxwell(mu, sigma).c_x(t))
6.35635234625645256156156145614561356E+00
```

dist_maxwell.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an Maxwell distribution:

$$K_X(t) = \log\left[M\left(\frac{3}{2}, \frac{1}{2}\frac{t^2}{2}\right) + \frac{2\sqrt{2}\,t}{\sqrt{\pi}} M\left(2, \frac{3}{2}, \frac{t^2}{2}\right)\right].$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", maxwell(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_maxwell.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \dots k$, of a random variable X, following an Maxwell distribution (Wikipedia). The raw moments are calculated from the central moments.

$$\mu_X(r) = \begin{cases} \sqrt{\frac{2}{\pi}} k! \alpha^{2k-1} & \text{for } n = 2k-1, \\ (n+1)!! \alpha^n & \text{for } n \text{ even}, \end{cases}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", maxwell(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_maxwell.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \dots k$, of a random variable X, following an Maxwell distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", maxwell(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.7.7 !!!Boost: Nakagami distribution

The following functions return the pdf, cdf, qtf or boost class of the Nakagami distribution with shape $m > 0$, scale $\omega > 0$, and the support interval $(0, +\infty)$.

See also Wikipedia [1189], MathWorld [254], Dharmawansa P and Ahmed [241], Hauberg [365], Ehrhardt [297] (3.9.22).

See also: https://reference.wolfram.com/language/ref/NakagamiDistribution.html

See also: https://mathworld.wolfram.com/PochhammerSymbol.html

math53.**nakagami_pdf**(*m*, *omega*, *x*)

Returns pdf(x), the value of the probability density function (*Pdf*) of the Nakagami distribution:

$$\text{pdf}(x) = \frac{2m^m x^{2m-1}}{\omega^m \Gamma(m)} \exp\left(-\frac{m}{\omega}x^2\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("NakagamiPdf(x, a, b): ", NakagamiPdf(x, a, b))
>>> print ("dist_nakagami(a, b).pdf(x): ", dist_nakagami(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

math53.**nakagami_cdf**(*m*, *omega*, *x*)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the Nakagami distribution:

$$\text{cdf}(x) = P\left(\frac{m}{\omega}x^2\right).$$

Here $P(\cdot)$ denotes the lower regularized incomplete gamma function (*RealGammaP*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("NakagamiCdf(x, a, b): ", NakagamiCdf(x, a, b))
>>> print ("dist_nakagami(a, b).cdf(x): ", dist_nakagami(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

math53.**nakagami_qtf**(*m*, *omega*, *q*)

Returns qtf(q), the value of the quantile function (*Qtf*) of the Nakagami distribution:

$$\text{qtf}(q) = \sqrt{\frac{\omega}{m}P^{-1}(m, q)}.$$

Here $P^{-1}(\cdot)$ denotes the inverse of the lower regularized incomplete gamma function (*RealGammaPInv*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("NakagamiQtf(q, a, b): ", NakagamiQtf(q, a, b))
>>> print ("dist_nakagami(a, b).qtf(q): ", dist_nakagami(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class ctx.**dist_nakagami**(*m*, *omega*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The Nakagami distribution is a continuous probability distribution with shape $m > 0$, scale $\omega > 0$, and the support interval $(0, +\infty)$. See also Wikipedia [1189], MathWorld [254], Witkovský [1490], Dharmawansa P and Ahmed [241], Hauberg [365].

Dharmawansa 2007: Characteristic function Hauberg 2005: Moments

dist_nakagami.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Nakagami distribution:

$$\text{pdf}_X(x) = \frac{2m^m x^{2m-1}}{\omega^m \Gamma(m)} \exp\left(-\frac{m}{\omega}x^2\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", nakagami(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_nakagami.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Nakagami distribution:

$$\text{cdf}_X(x) = P\left(\frac{m}{\omega}x^2\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", nakagami(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_nakagami.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following an Nakagami distribution:

$$\text{sf}_X(x) = Q\left(\frac{m}{\omega}x^2\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", nakagami(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_nakagami.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following an Nakagami distribution:

$$\text{qtf}_X(q) = \sqrt{\frac{\omega}{m}P^{-1}(m, q)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", nakagami(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145614561356E+00
```

dist_nakagami.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following an Nakagami distribution:

$$\text{isf}_X(q) = \sqrt{\frac{\omega}{m} Q^{-1}(m, q)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", nakagami(mu, sigma).isf(q))
6.35635234625645256156156145614561356E+00
```

dist_nakagami.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an Nakagami distribution:

$$C_X(t) = \frac{\Gamma(2m)}{2^{m-1}\Gamma(m)} \exp\left(-\frac{\omega}{8m}t^2\right) D_{-2m}\left(-it\sqrt{\frac{\omega}{2m}}\right).$$

Dharmawansa 2007: Characteristic function

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", nakagami(mu, sigma).c_x(t))
6.35635234625645256156156145614561356E+00
```

dist_nakagami.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following an Nakagami distribution:

$$M_X(t) = \frac{\Gamma(2m)}{2^{m-1}\Gamma(m)} \exp\left(-\frac{\omega}{8m}t^2\right) D_{-2m}\left(-t\sqrt{\frac{\omega}{2m}}\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", nakagami(mu, sigma).c_x(t))
6.35635234625645256156156145614561356E+00
```

dist_nakagami.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an Nakagami distribution:

$$K_X(t) = \log\left[\frac{\Gamma(2m)}{2^{m-1}\Gamma(m)} \exp\left(-\frac{\omega}{8m}t^2\right) D_{-2m}\left(-t\sqrt{\frac{\omega}{2m}}\right)\right].$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", nakagami(mu, sigma).k_x(t, k))
6.356352346256452561561561456135 6E+00
```

dist_nakagami.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an Nakagami distribution (Wikipedia). The raw moments are calculated from the central moments.

$$\mu_X(n) = tbd.$$

Hauberg 2005: Moments

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", nakagami(mu, sigma).moments(k))
6.356352346256452561561561456135 6E+00
```

dist_nakagami.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an Nakagami distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", nakagami(mu, sigma).cumulants(k))
6.356352346256452561561561456135 6E+00
```

4.7.8 Amoroso distribution

class ctx.**dist_amoroso**(a, b)

where ctx is dec, mpm, ipm, fpm, gmp or arb.

The Amoroso distribution distribution is a continuous probability distribution with parameters $a > 0$ and $b > 0$, and the support interval $(0, +\infty)$.

See also Crooks [188], Crooks [187].

dist_amoroso.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a Amoroso distribution:

$$\text{pdf}_X(x) = \frac{|\beta|}{\Gamma(\alpha)|\theta|}\left(\frac{x-a}{\theta}\right)^{\alpha\beta-1}\exp\left(-\left(\frac{x-a}{\theta}\right)^{\beta}\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", fisher_f(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_amoroso.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Amoroso distribution:

$$\text{cdf}_X(x) = P(\alpha, z) \quad \text{for } \beta/\theta > 0, \quad \text{where } z = \left(\frac{x-a}{\theta}\right)^{\beta}$$

$$\text{cdf}_X(x) = Q(\alpha, z) \quad \text{for } \beta/\theta < 0, \quad \text{where } z = \left(\frac{x-a}{\theta}\right)^{\beta}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", fisher_f(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_amoroso.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following a Amoroso distribution:

$$\text{sf}_X(x) = Q(\alpha, z) \quad \text{for } \beta/\theta < 0 \quad \text{where } z = \left(\frac{x-a}{\theta}\right)^{\beta}$$

$$\text{sf}_X(x) = P(\alpha, z) \quad \text{for } \beta/\theta > 0, \quad \text{where } z = \left(\frac{x-a}{\theta}\right)^{\beta}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_f(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_amoroso.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Amoroso distribution:

$$\text{qtf}_X(q) = a + \theta \cdot z^{1/\beta}; z = P^{-1}(\alpha, q) \quad \text{for } \beta/\theta > 0$$

$$\text{qtf}_X(q) = a + \theta \cdot z^{1/\beta}; z = Q^{-1}(\alpha, q) \quad \text{for } \beta/\theta < 0$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_f(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_amoroso.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Amoroso distribution:

$$\text{isf}_X(q) = a + \theta \cdot z^{1/\beta}; z = Q^{-1}(\alpha, q) \quad \text{for } \beta/\theta > 0$$

$$\text{isf}_X(q) = a + \theta \cdot z^{1/\beta}; z = P^{-1}(\alpha, q) \quad \text{for } \beta/\theta < 0$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_amoroso.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Amoroso distribution:

$$C_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_f(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_amoroso.**m_x**(t)

Returns `NaN`, since the moment generating function does not exist.

dist_amoroso.**k_x**(t, *k=0*)

Returns `NaN`, since the cumulant generating function does not exist.

dist_amoroso.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Amoroso distribution. The rth moments only exists for $n_2 > 2r$.

$$\mu'_X(r) = ??$$

Standard moments:

$$\mu'_X(r) = \frac{\Gamma(\alpha + r/\beta)}{\Gamma(\alpha)}, \quad \alpha + r/\beta) > 0$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).moments(k))
6.35635234625645256156156145613356E+00
```

dist_amoroso.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a Amoroso distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).cumulants(k))
6.35635234625645256156156145613356E+00
```

4.7.9 Distribution of the logarithm of a χ^2 random variable

class ctx.**dist_logrv_chisquared**(n)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of the logarithm of a χ^2 random variable with n degrees of freedom is a continuous probability distribution with the support interval $(-\infty, +\infty)$. See also Witkovský [1466].

dist_logrv_chisquared.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of the logarithm of a χ^2 random variable:

$$\mathrm{pdf}_X(x) = e^x f_{\chi^2}\left(e^x, n\right),$$

Here $f_{\chi^2}(\cdot, n)$ denotes the pdf of a random variable following an chi-squared distribution with n degress of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", logrv_chisquared(mu, sigma).pdf(x))
6.35635234625645256156156145613356E-20
```

dist_logrv_chisquared.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of the logarithm of a χ^2 random variable:

$$\mathrm{cdf}_X(x) = F_{\chi^2}\left(e^x, n\right) = P(n/2, e^{x/2}),$$

Here $F_{\chi^2}(\cdot, n)$ denotes the cdf of a random variable following an chi-squared distribution with n degress of freedom, and $P(\cdot)$ is the lower regularized gamma function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", logrv_chisquared(mu, sigma).pdf(x))
6.35635234625645256156156145613356E-20
```

dist_logrv_chisquared.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following the distribution of the logarithm of a χ^2 random variable:

$$\mathrm{sf}_X(x) = 1 - F_{\chi^2}\left(e^x, n\right) = Q(n/2, e^{x/2}).$$

Here $1 - F_{\chi^2}(\cdot, n)$ denotes the sf of a random variable following an chi-squared distribution with n degress of freedom, and $Q(\cdot)$ is the upper regularized gamma function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", logrv_chisquared(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613356E-20
```

dist_logrv_chisquared.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following the distribution of the logarithm of a χ^2 random variable:

$$\text{qtf}_X(q) = \log\left(2P^{-1}(n/2, q)\right).$$

Here $P^{-1}(\cdot)$ denotes the inverse of the lower regularized incomplete gamma function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", logrv_chisquared(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_logrv_chisquared.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of the logarithm of a χ^2 random variable:

$$\text{qtf}_X(q) = \log\left(2Q^{-1}(n/2, q)\right).$$

Here $Q^{-1}(\cdot)$ denotes the inverse of the upper regularized incomplete gamma function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", logrv_chisquared(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_logrv_chisquared.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of the logarithm of a χ^2 random variable:

$$C_X(t) = 2^{it}\frac{\Gamma(n/2 + it)}{\Gamma(n/2)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", logrv_chisquared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_logrv_chisquared.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following the distribution of the logarithm of a χ^2 random variable:

$$M_X(t) = 2^{t}\frac{\Gamma(n/2 + t)}{\Gamma(n/2)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", logrv_chisquared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_logrv_chisquared.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(t), j = 1 \ldots k$, of a random variable X, following the distribution of the logarithm of a χ^2 random variable:

$$K_X(t) = t \cdot \log(2) + \log\left(\Gamma(n/2 + t)\right) - \log\left(\Gamma(n/2)\right)$$

$$K_X^{(1)}(t) = \log(2) + \psi^{(0)}(n/2 + t),$$

$$K_X^{(j)}(t) = \psi^{(j-1)}(n/2 + t), \quad j \geq 2.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", logrv_chisquared(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_logrv_chisquared.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of the logarithm of a χ^2 random variable: the moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", logrv_chisquared(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_logrv_chisquared.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of the logarithm of a χ^2 random variable:

$$\kappa_1 = \log(2) + \psi^{(0)}(n/2),$$

$$\kappa_r = \psi^{(r-1)}(n/2), \quad r \geq 2,$$

where $\psi^{(r)}(\cdot)$ is the polygamma function of order r.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", logrv_chisquared(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

Approximations

ctx.**logrv_chisquared_ecf**(*x*, *f*, *results='cdf'*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Edgeworth approximation to the pdf, cdf and sf.

ctx.**logrv_chisquared_ecf_inv**(*q*, *f*, *results='qtf'*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Cornish-Fisher approximation to the qtf and isf.

4.7.10 Hypoexponential (Generalized Erlang) Distribution

class ctx.**dist_hypoexponential**(*n*, *lambdaj*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The hypoexponential distribution is a continuous probability distribution with n rate parameters $\lambda_j > 0, j = 1 \dots n$, and the support interval $(0, +\infty)$. It is the distribution of the sum of n independent exponential variables with parameters λ_j. It is called the hypoexponential distribution as it has a coefficient of variation less than one, compared to the hyperexponential distribution which has coefficient of variation greater than one and the exponential distribution which has coefficient of variation of one. If all parameters are equal ($\lambda_j = \lambda$), the hypoexponential distribution is identical with the Erlang distribution (which is a special case of the gamma distribution wherein the shape parameter of the distribution is an integer).

See also: Wikipedia [1214], Wikipedia [1201], MathWorld [250], Chesneau [176], Smaili K. [503].

dist_hypoexponential.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a hypoexponential distribution:

$$\text{pdf}_X(x) = \begin{cases} \dfrac{\lambda^n x^{n-1} e^{-\lambda x}}{(n-1)!} & \text{for all parameters equal: } \lambda_j = \lambda, \\ \displaystyle\sum_{j=1}^{n} \frac{\lambda_j}{d_j} e^{-\lambda_j x} & \text{for all parameters distinct: } \lambda_j \neq \lambda_k \text{ for } j \neq k, \\ -\boldsymbol{\alpha} e^{x\Theta} \Theta \mathbf{1} & \text{for general parameters: } \lambda_j > 0, \end{cases}$$

where $\boldsymbol{\alpha} = (1, 0, \dots, 0)$, $\mathbf{1}$ is a column vector of ones of the size n, e^A is the matrix exponential of A, and

$$d_j = \prod_{k=1, k\neq j}^{n} \left(1 - \frac{\lambda_j}{\lambda_k}\right), \quad \Theta = \begin{bmatrix} -\lambda_1 & \lambda_1 & 0 & \dots & 0 & 0 \\ 0 & -\lambda_2 & \lambda_2 & \ddots & 0 & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & \vdots \\ 0 & 0 & \ddots & -\lambda_{n-2} & \lambda_{n-2} & 0 \\ 0 & 0 & \dots & 0 & -\lambda_{n-1} & \lambda_{n-1} \\ 0 & 0 & \dots & 0 & 0 & -\lambda_n \end{bmatrix}. \tag{4.1}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", mp_hypoexponential(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_hypoexponential.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a hypoexponential distribution:

$$\text{cdf}_X(x) = \begin{cases} P(n, \lambda x) & \text{for all parameters equal: } \lambda_j = \lambda, \\ 1 - \displaystyle\sum_{j=1}^{n} \frac{1}{d_j} e^{-\lambda_j x} & \text{for all parameters distinct: } \lambda_j \neq \lambda_k \text{ for } j \neq k, \\ 1 - \boldsymbol{\alpha} e^{x\Theta} \mathbf{1} & \text{for general parameters: } \lambda_j > 0, \end{cases}$$

where $P(\cdot)$ is the lower regularized gamma function, d_j and Θ are defined in equation (4.1), $\boldsymbol{\alpha} = (1, 0, \dots, 0)$, $\mathbf{1}$ is a column vector of ones of the size n, and e^A is the matrix exponential of A.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", mp_hypoexponential(mu, sigma).pdf(x))
6.356352346256452561561561561456 1356E-20
```

`dist_hypoexponential.sf(`x`)`

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following a hypoexponential distribution:

$$\mathrm{sf}_X(x) = \begin{cases} Q(n, \lambda x) & \text{for all parameters equal: } \lambda_j = \lambda, \\ \displaystyle\sum_{j=1}^{n} \frac{1}{d_j} e^{-\lambda_j x} & \text{for all parameters distinct: } \lambda_j \neq \lambda_k \text{ for } j \neq k, \\ \boldsymbol{\alpha} e^{x\Theta} \mathbf{1} & \text{for general parameters: } \lambda_j > 0, \end{cases}$$

where $Q(\cdot)$ is the upper regularized gamma function, d_j and Θ are defined in equation (4.1), $\boldsymbol{\alpha} = (1, 0, \ldots, 0)$, $\mathbf{1}$ is a column vector of ones of the size n, and e^A is the matrix exponential of A.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", mp_hypoexponential(mu, sigma).pdf(x))
sf: 6.356352346256452561561561561456 1356E-20
```

`dist_hypoexponential.qtf(`q`)`

Returns $\mathrm{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following a hypoexponential distribution.

There is no known closed form for $\mathrm{qtf}_X(q)$ or $\mathrm{isf}_X(q)$: These functions are computed with Newton iterations where the starting values are from the corresponding Boost functions (in double precision).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", mp_hypoexponential(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561456 1356E+00
```

`dist_hypoexponential.isf(`q`)`

Returns $\mathrm{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following a hypoexponential distribution.

There is no known closed form for $\mathrm{qtf}_X(q)$ or $\mathrm{isf}_X(q)$: These functions are computed with Newton iterations where the starting values are from the corresponding Boost functions (in double precision).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", mp_hypoexponential(mu, sigma).isf(q))
6.356352346256452561561561561456 1356E+00
```

`dist_hypoexponential.c_x(`t`)`

Returns $C_X(t)$, the characteristic function of a random variable X, following a hypoexponential distribution:

$$C_X(t) = \prod_{j=1}^{n} \frac{\lambda_j}{\lambda_j - it}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_hypoexponential(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_hypoexponential.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following a hypoexponential distribution:

$$M_X(t) = \prod_{j=1}^{n} \frac{\lambda_j}{\lambda_j - t}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_hypoexponential(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_hypoexponential.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a hypoexponential distribution:

$$K_X(t) = \sum_{j=1}^{n} \log\left(\frac{\lambda_j}{\lambda_j - t}\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", mp_hypoexponential(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_hypoexponential.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a hypoexponential distribution. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_hypoexponential(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_hypoexponential.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a hypoexponential distribution. The cumulants are given by

$$\kappa_X(r) = (r-1)! \sum_{j=1}^{n} \frac{1}{\lambda_j^r}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_hypoexponential(mu, sigma).cumulants(k))
6.356352346256452561561561561456135 6E+00
```

4.7.11 Lindley distribution (generalized)

class ctx.**dist_lindley**(b)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The Lindley distribution is a continuous probability distribution with scale $b > 0$, and the support interval $(0, +\infty)$.

See also: Al-Babtain *et al.* [7], Zakerzadeh and Dolati [1501], Lindley [409].

dist_lindley.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Lindley distribution:

$$\mathrm{pdf}_X(x) = \frac{\theta^2}{\eta + \theta k}\left(\frac{k(\theta x)^{\alpha-1}}{\Gamma(\alpha)} + \frac{\eta(\theta x)^{\beta-1}}{\theta\Gamma(\beta)}\right)e^{-\theta x}, \quad x > 0.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", lindley(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_lindley.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Lindley distribution:

$$\mathrm{cdf}_X(x) = \frac{1}{\eta + \theta k}\left(\theta k P(\alpha, \theta x) + \eta P(\beta, \theta x)\right), \quad x > 0.$$

$$\mathrm{cdf}_X(x) = w \cdot P(\alpha, \theta x) + (1 - w) \cdot P(\beta, \theta x), \quad w = \frac{\theta k}{\eta + \theta k}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", lindley(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_lindley.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following an Lindley distribution:

$$\mathrm{sf}_X(x) = 1 - \frac{1}{\eta + \theta k}\left(\theta k P(\alpha, \theta x) + \eta P(\beta, \theta x)\right), \quad x > 0.$$

$$\mathrm{sf}_X(x) = w \cdot Q(\alpha, \theta x) + (1 - w) \cdot Q(\beta, \theta x), \quad w = \frac{\theta k}{\eta + \theta k}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", lindley(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_lindley.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following an Lindley distribution:

$$\text{qtf}_X(q) = \frac{1}{\theta}\left(w \cdot P^{-1}(\alpha, q) + (1-w) \cdot P^{-1}(\beta, q)\right), \quad w = \frac{\theta k}{\eta + \theta k}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", lindley(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_lindley.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following an Lindley distribution:

$$\text{isf}_X(q) = \frac{1}{\theta}\left(w \cdot Q^{-1}(\alpha, q) + (1-w) \cdot Q^{-1}(\beta, q)\right), \quad w = \frac{\theta k}{\eta + \theta k}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", lindley(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_lindley.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an Lindley distribution:

$$C_X(t) = \frac{1}{\eta + \theta k}\left[\theta k \left(1 - \frac{it}{\theta}\right)^{-\alpha} + \eta \left(1 - \frac{it}{\theta}\right)^{-\beta}\right].$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", lindley(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_lindley.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following an Lindley distribution:

$$M_X(t) = \frac{1}{\eta + \theta k}\left[\theta k \left(1 - \frac{t}{\theta}\right)^{-\alpha} + \eta \left(1 - \frac{t}{\theta}\right)^{-\beta}\right].$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", lindley(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_lindley.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an Lindley distribution:

$$K_X(t) = \log\left(M(t)\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", lindley(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_lindley.**moments**(*k*)

Returns the first j raw moments, $\mu'_j, j = 1 \ldots k$, of a random variable X, following an Lindley distribution (Wikipedia). The raw moments are given by

$$\mu'_X(k) = \frac{\alpha(\alpha+1)\cdots(\alpha+r-1)\theta k + \beta(\beta+1)\cdots(\beta+r-1)\eta}{\theta^r(\eta+\theta k)}.$$

$$\mu'_X(k) = \frac{w}{\theta^r}\frac{\Gamma(\alpha+r)}{\Gamma(\alpha)} + \frac{1-w}{\theta^r}\frac{\Gamma(\beta+r)}{\Gamma(\beta)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", lindley(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_lindley.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an Lindley distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", lindley(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.7.12 Skew exponential power distribution

class ctx.**skewexponpower**(a, b)

where ctx is dec, mpm, ipm, fpm, gmp or arb.

The skew exponential power distribution is a continuous probability distribution with parameters $a > 0$ and $b > 0$, and the support interval $(0, +\infty)$.

See also: Hutson [377], Kleiber and Kotz [393] (p. 131), Wikipedia [1213], MathWorld [247].

skewexponpower.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a skew exponential power distribution:

$$\mathrm{pdf}_X(x) = \frac{1}{k\sigma} \exp\left(-\tfrac{1}{2}\left(|z| + (2\alpha - 1)z\right)\right)^{1/c}, \quad \text{where } c = \frac{1+\beta}{2}, \quad k = \frac{4\alpha(1-\alpha)}{\Gamma(1+c)2^{1+c}}, \quad z = \frac{x-\theta}{\sigma}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", fisher_f(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

skewexponpower.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a skew exponential power distribution:

$$\mathrm{cdf}_X(x) = \begin{cases} \alpha P\left(c, 2^{(1/c)-1}((\alpha-1)z)^{1/c}\right) & \text{if } z \le 0 \\ 1 - (1-\alpha)P\left(c, 2^{(1/c)-1}(\alpha z)^{1/c}\right) & \text{if } z > 0 \end{cases}, \quad \text{where } c = \frac{1+\beta}{2}, \quad z = \frac{x-\theta}{\sigma}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", fisher_f(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

skewexponpower.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a skew exponential power distribution:

$$\mathrm{sf}_X(x) = \begin{cases} 1 - \alpha P\left(c, 2^{(1/c)-1}((\alpha-1)z)^{1/c}\right) & \text{if } z \le 0 \\ (1-\alpha)P\left(c, 2^{(1/c)-1}(\alpha z)^{1/c}\right) & \text{if } z > 0 \end{cases}, \quad \text{where } c = \frac{1+\beta}{2}, \quad z = \frac{x-\theta}{\sigma}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_f(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

skewexponpower.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a skew exponential power distribution:

$$\text{qtf}_X(q) = \begin{cases} \theta + \frac{\sigma}{1-\alpha}\left(2^{((1/c)-1)/2}\sqrt{P^{-1}\left(c, q/\alpha\right)}\right)^{\beta+1} & \text{if } q \leq \alpha \\ \theta + \frac{\sigma}{\alpha}\left(2^{((1/c)-1)/2}\sqrt{P^{-1}\left(c, (1-q)/(1-\alpha)\right)}\right)^{\beta+1} & \text{if } q > \alpha \end{cases}, \quad \text{where } c = \frac{1+\beta}{2}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_f(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561456 1356E+00
```

skewexponpower.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a skew exponential power distribution:

$$\text{isf}_X(q) = \begin{cases} \theta + \frac{\sigma}{1-\alpha}\left(2^{((1/c)-1)/2}\sqrt{P^{-1}\left(c, q/\alpha\right)}\right)^{\beta+1} & \text{if } q \leq \alpha \\ \theta + \frac{\sigma}{\alpha}\left(2^{((1/c)-1)/2}\sqrt{P^{-1}\left(c, (1-q)/(1-\alpha)\right)}\right)^{\beta+1} & \text{if } q > \alpha \end{cases}, \quad \text{where } c = \frac{1+\beta}{2}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.356352346256452561561561456 1356E+00
```

skewexponpower.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a skew exponential power distribution:

$$C_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_f(mu, sigma).c_x(t))
6.356352346256452561561561456 1356E+00
```

skewexponpower.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a skew exponential power distribution:

$$M_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_f(mu, sigma).c_x(t))
6.356352346256452561561561456 1356E+00
```

skewexponpower.**k_x**(t, k=*0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a skew exponential power distribution:

$$K_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_f(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

skewexponpower.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a skew exponential power distribution. All moments exist. The moments of $Z = (X - \theta)/\sigma$ are given by

$$\mu'_Z(r) = \frac{(\beta+1)\cdot\left((-2)^r\alpha^{r+1} + (1-\alpha)(2(1-\alpha))^r\right)\cdot 2^{(\beta-3)r/2-1}\cdot\Gamma((\beta+1)(r+1)/2)}{(1-\alpha)^r\alpha^r\Gamma((\beta+3)/2)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

skewexponpower.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a skew exponential power distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.7.13 Stacy (generalized gamma) distribution

class ctx.**dist_stacy**(a, b)

where ctx is dec, mpm, ipm, fpm, gmp or arb.

The Stacy distribution distribution is a continuous probability distribution with parameters $a > 0$ and $b > 0$, and the support interval $(0, +\infty)$.

See also Wikipedia [1211], Crooks [187] (p.87).

dist_stacy.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a Stacy distribution:

$$\mathrm{pdf}_X(x) = \frac{|\beta|}{\Gamma(\alpha)|\theta|}\left(\frac{x}{\theta}\right)^{\alpha\beta-1}\exp\left(-\left(\frac{x}{\theta}\right)^{\beta}\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", fisher_f(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_stacy.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Stacy distribution:

$$\mathrm{cdf}_X(x) = P(\alpha, z) \quad \text{for } \beta/\theta > 0, \quad \text{where } z = \left(\frac{x}{\theta}\right)^{\beta}$$

$$\mathrm{cdf}_X(x) = Q(\alpha, z) \quad \text{for } \beta/\theta < 0, \quad \text{where } z = \left(\frac{x}{\theta}\right)^{\beta}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", fisher_f(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_stacy.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a Stacy distribution:

$$\mathrm{sf}_X(x) = Q(\alpha, z) \quad \text{for } \beta/\theta < 0 \quad \text{where } z = \left(\frac{x}{\theta}\right)^{\beta}$$

$$\mathrm{sf}_X(x) = P(\alpha, z) \quad \text{for } \beta/\theta > 0, \quad \text{where } z = \left(\frac{x}{\theta}\right)^{\beta}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_f(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_stacy.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Stacy distribution:

$$\text{qtf}_X(q) = \theta \cdot z^{1/\beta}; z = P^{-1}(\alpha, q) \quad \text{for } \beta/\theta > 0$$

$$\text{qtf}_X(q) = \theta \cdot z^{1/\beta}; z = Q^{-1}(\alpha, q) \quad \text{for } \beta/\theta < 0$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_f(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_stacy.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Stacy distribution:

$$\text{isf}_X(q) = \theta \cdot z^{1/\beta}; z = Q^{-1}(\alpha, q) \quad \text{for } \beta/\theta > 0$$

$$\text{isf}_X(q) = \theta \cdot z^{1/\beta}; z = P^{-1}(\alpha, q) \quad \text{for } \beta/\theta < 0$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_stacy.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Stacy distribution:

$$C_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_f(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_stacy.**m_x**(t)

Returns `NaN`, since the moment generating function does not exist.

dist_stacy.**k_x**(t, *k=0*)

Returns `NaN`, since the cumulant generating function does not exist.

dist_stacy.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Stacy distribution. The rth moments only exists for $n_2 > 2r$.

$$\mu'_X(r) = ??$$

Standard moments:

$$\mu'_X(r) = \frac{\Gamma(\alpha + r/\beta)}{\Gamma(\alpha)}, \quad \alpha + r/\beta) > 0$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).moments(k))
6.35635234625645256156156145613356E+00
```

dist_stacy.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a Stacy distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).cumulants(k))
6.35635234625645256156156145613356E+00
```

4.8 Closed form distributions, based on the incomplete beta function

4.8.1 Boost: Beta (Pearson Type I and II) distribution

Returns the pdf, cdf, qtf or boost class of a random variable X, following a beta distribution with parameters $a > 0$, $b > 0$, and the support interval $(0, 1)$.

See also Wikipedia [1148], MathWorld [797], BoostMath [51], Ehrhardt [297] (3.9.2).

math53.**beta_pdf**(a, b, x)

Returns $\text{pdf}(x)$, the value of the probability density function (*Pdf*) of the beta distribution:

$$\text{pdf}(x) = f_{\text{Beta}}(a, b, x) = \frac{1}{B(a, b)} x^{a-1}(1 - x)^{b-1}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("BetaPdf(x, a, b): ", BetaPdf(x, a, b))
>>> print ("dist_beta(a, b).pdf(x): ", dist_beta(a, b).pdf(x))
6.356352346256452561561561561456135 6E+00
```

math53.**beta_cdf**(a, b, x)

Returns $\text{cdf}(x)$, the value of the cumulative distribution function (*Cdf*) of the beta distribution:

$$\text{cdf}(x) = I_x(a, b) = \text{ibeta}(a, b, x).$$

Here $\text{ibeta}(\cdot)$ denotes the real normalised incomplete beta function (*RealIBeta*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("BetaCdf(x, a, b): ", BetaCdf(x, a, b))
>>> print ("dist_beta(a, b).cdf(x): ", dist_beta(a, b).cdf(x))
6.356352346256452561561561561456135 6E+00
```

math53.**beta_qtf**(a, b, q)

Returns $\text{qtf}(q)$, the value of the quantile function (*Qtf*) of the beta distribution:

$$\text{qtf}(q) = \text{ibeta_inv}(a, b, q).$$

Here $\text{ibeta_inv}(\cdot)$ denotes the inverse of the real normalised incomplete beta function (*RealIBetaInv*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("BetaQtf(q, a, b): ", BetaQtf(q, a, b))
>>> print ("dist_beta(a, b).qtf(q): ", dist_beta(a, b).qtf(q))
6.356352346256452561561561561456135 6E+00
```

class ctx.**dist_beta**(a, b)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The beta distribution is a continuous probability distribution with parameters $a > 0$, $b > 0$, and the support interval $(0, 1)$. See also Wikipedia [1148], MathWorld [797], BoostMath [51], Witkovský [1465], R (Statistical System) [520].

See also: https://docs.scipy.org/doc/scipy/reference/generated/scipy.special.btdtrib.html#scipy.special.btdtrib

dist_beta.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a beta distribution:

$$\mathrm{pdf}_X(x) = f_{\mathrm{Beta}}(a, b, x) = \frac{1}{B(a, b)} x^{a-1}(1-x)^{b-1}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", beta(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_beta.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a beta distribution:

$$\mathrm{cdf}_X(x) = I_x(a, b) = \mathrm{ibeta}(a, b, x).$$

Here $\mathrm{ibeta}(\cdot)$ denotes the real normalised incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", beta(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_beta.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a beta distribution:

$$\mathrm{sf}_X(x) = 1 - I_x(a, b) = \mathrm{ibetac}(a, b, x).$$

Here $\mathrm{ibetac}(\cdot)$ denotes the real normalised complementary incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", beta(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_beta.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a beta distribution:

$$\text{qtf}_X(q) = \text{ibeta_inv}(a, b, q).$$

Here $\text{ibeta_inv}(\cdot)$ denotes the inverse of the real normalised incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", beta(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_beta.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a beta distribution:

$$\text{isf}_X(q) = \text{ibetac_inv}(a, b, q).$$

Here $\text{ibetac_inv}(\cdot)$ denotes the inverse of the real normalised complementary incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", beta(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_beta.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a beta distribution:

$$C_X(t) = {}_1F_1(a, a + b; it).$$

where ${}_1F_1()$ is Kummer's confluent hypergeometric function (of the first kind).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", beta(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_beta.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a beta distribution:

$$M_X(t) = {}_1F_1(a, a + b; t).$$

where ${}_1F_1()$ is Kummer's confluent hypergeometric function (of the first kind).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", beta(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_beta.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(t), j = 1 \ldots k$, of a random variable X, following a beta distribution:

$$K_X(t) = \log({}_1F_1(a, a+b; t)),$$

$$K_X^{(j)}(t) = tbd.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", beta(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_beta.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a beta distribution: the moments are calculated from the cumulants.

$$\mu'_h = \frac{\Gamma(a+h)\Gamma(a+b)}{\Gamma(a)\Gamma(a+b+h)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", beta(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_beta.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a beta distribution: The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", beta(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

Recurrences: Central Beta

ctx.**beta_recurrence**(*x*, *n*, *lambda*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The following recurrence relations hold for the pdf and CDF:

$$I(a,b;x) = 1 - I(b,a;1-x) \tag{4.2}$$

$$I(a,b;x) = \binom{n}{a} x^a (1-x)^{b-1} + I(a+1, b-1; x) \tag{4.3}$$

$$I(a,b;x) = \binom{n}{a} x^a (1-x)^b + I(a+1, b; x) \tag{4.4}$$

$$I(a,b+1;x) = \binom{n}{a} x^a (1-x)^b + I(a, b; x) \tag{4.5}$$

$$I(a,b;x) = \binom{n}{a+b} x^a (1-x)^b \frac{a}{a+b-x} + I(a+1, b+1; x) \tag{4.6}$$

$$I(a,b;x) = F\left(2a, 2b, \frac{nx}{m-mx}\right) \tag{4.7}$$

4.8.2 Boost: Central Fisher F distribution

The following functions return the pdf, cdf, qtf or boost class of the Fisher F distribution with $m > 0$ and $n > 0$ degrees of freedom, and the support interval $(0, +\infty)$.

See also Wikipedia [1153], MathWorld [801], BoostMath [56], Ehrhardt [297] (3.9.9).

`math53.fisher_f_pdf(m, n, x)`

Returns pdf(x), the value of the probability density function (*Pdf*) of the Fisher F distribution:

$$\text{pdf}(x) = \frac{m^{m/2} n^{n/2}}{B(m/2, n/2)} x^{(m-2)/2} (n + mx)^{-(m+n)/2}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("FisherFPdf(x, a, b): ", FisherFPdf(x, a, b))
>>> print ("dist_fisher_f(a, b).pdf(x): ", dist_fisher_f(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.fisher_f_cdf(m, n, x)`

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the Fisher F distribution:

$$\text{cdf}(x) = \begin{cases} \text{ibetac}(n/2, m/2, n/(n + mx)), & mx > n, \\ \text{ibeta}(m/2, n/2, mx/(n + mx)) & mx \le n. \end{cases}$$

Here ibeta$(\cdot)$ denotes the real normalised incomplete beta function (*RealIBeta*), and ibetac$(\cdot)$ denotes the real normalised complementary incomplete beta function (*RealIBetac*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("FisherFCdf(x, a, b): ", FisherFCdf(x, a, b))
>>> print ("dist_fisher_f(a, b).cdf(x): ", dist_fisher_f(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.fisher_f_qtf(m, n, q)`

Returns qtf(q), the value of the quantile function (*Qtf*) of the Fisher F distribution:

$$\text{qtf}(q) = \frac{nx}{m(1 - x)}, \quad \text{where } x = \text{ibeta_inv}(m/2, n/2, q).$$

Here ibeta_inv$(\cdot)$ denotes the inverse of the real normalised incomplete beta function (*RealIBetaInv*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("FisherFQtf(q, a, b): ", FisherFQtf(q, a, b))
>>> print ("dist_fisher_f(a, b).qtf(q): ", dist_fisher_f(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class ctx.**dist_fisher_f**(m, n)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The Fisher F-distribution is a continuous probability distribution with $m > 0$ and $n > 0$ degrees of freedom, and the support interval $(0, +\infty)$. See also Wikipedia [1153], MathWorld [801], BoostMath [56], Witkovský [1468], R (Statistical System) [524], Abramowitz and Stegun. [3], Butler and Paolella [166], Chattamvelli and Jones [175], Witkovský [1462].

dist_fisher_f.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a central Fisher F distribution:

$$\mathrm{pdf}_X(x) = \frac{m^{m/2} n^{n/2}}{B(m/2, n/2)} x^{(m-2)/2} (n + mx)^{-(m+n)/2},$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", fisher_f(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_fisher_f.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a central Fisher F distribution:

$$\mathrm{cdf}_X(x) = \begin{cases} \mathrm{ibetac}(n/2, m/2, n/(n + mx)), & mx > n, \\ \mathrm{ibeta}(m/2, n/2, mx/(n + mx)) & mx \leq n. \end{cases}$$

Here $\mathrm{ibeta}(\cdot)$ denotes the real normalised incomplete beta function, and $\mathrm{ibetac}(\cdot)$ denotes the real normalised complementary incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", fisher_f(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_fisher_f.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a central Fisher F distribution:

$$\mathrm{sf}_X(x) = \begin{cases} \mathrm{ibeta}(n/2, m/2, n/(n + mx)), & mx > n, \\ \mathrm{ibetac}(m/2, n/2, mx/(n + mx)) & mx \leq n. \end{cases}$$

Here $\mathrm{ibeta}(\cdot)$ denotes the real normalised incomplete beta function, and $\mathrm{ibetac}(\cdot)$ denotes the real normalised complementary incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_f(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_fisher_f.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a central Fisher F distribution:

$$\text{qtf}_X(q) = \frac{nx}{m(1-x)}, \quad \text{where } x = \text{ibeta_inv}(m/2, n/2, q).$$

Here $\text{ibeta_inv}(\cdot)$ denotes the inverse of the real normalised incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_f(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_fisher_f.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a central Fisher F distribution:

$$\text{isf}_X(q) = \frac{nx}{m(1-x)}, \quad \text{where } x = \text{ibetac_inv}(m/2, n/2, q).$$

Here $\text{ibetac_inv}(\cdot)$ denotes the inverse of the real normalised complementary incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_fisher_f.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a central Fisher F distribution:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \mathrm{d}x = \frac{\Gamma(m/2+n/2)}{\Gamma(n/2)} U\left(\frac{m}{2}, 1-\frac{n}{2}, -\frac{n}{m}it\right)$$

where $U(\cdot)$ denotes the confluent hypergeometric function of the second kind.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_f(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_fisher_f.**m_x**(t)

Returns `NaN`, since the moment generating function does not exist.

dist_fisher_f.**k_x**(t, *k=0*)

Returns `NaN`, since the cumulant generating function does not exist.

dist_fisher_f.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a central Fisher F distribution. The rth moments only exists for $n_2 > 2r$.

$$\mu'_X(r) = \mu'_F(r) = \frac{\Gamma(\frac{1}{2}n_1 + r) - \Gamma(\frac{1}{2}n_2 - r)}{\Gamma(\frac{1}{2}n_2)}, \quad \text{for } n_2 > 2r.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).moments(k))
6.356352346256452561561561456135 6E+00
```

dist_fisher_f.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a central Fisher F distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).cumulants(k))
6.356352346256452561561561456135 6E+00
```

Additional methods: Recurrence relations

Let the density $g_{m,n}$ be that of m/n times an $F_{m,n}$ random variable. Let $G_{m,n}(y)$ be its distribution function.

Then the following recurrence relations hold (see Chattamvelli, 1995)

dist_fisher_f.**recurrence_pdf**(*x*, *lambda*, *start_n1*, *start_n2*, *target_n1*, *target_n2*)

Applies a recurrence relation to calculate the cdf for different degrees of freedom for a given value of *x*. This is mostly useful when using asymptotic methods.

$$n\left[G_{m,n+2}(y) - G_{m-2,n+2}(y)\right] = -2g_{m,n}(y)$$

$$m(1+y)]g_{m+2,n}(y) + y(m+n)g_{m,n}(y).$$

$$n(1+y)g_{m,n+2}(y) = (m+n)g_{m,n}(y).$$

$$mg_{m+2,n-2}(y) = (n-2)yg_{m,n}(y).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", fisher_f(mu, sigma).k_x(t, k))
6.356352346256452561561561456135 6E+00
```

dist_fisher_f.**recurrence_cdf**(*x*, *lambda*, *start_n1*, *start_n2*, *target_n1*, *target_n2*)

Applies a recurrence relation to calculate the cdf for different degrees of freedom for a given value of *x*. This is mostly useful when using asymptotic methods.

From these equations we obtain

$$\begin{aligned}[(m+2)(1+y)]G_{m+4,n}(y) &= [(m+2)(1+y) + y(m+n]G_{m+2,n}(y) \\ &- y(m+n)G_{m,n}(y)\end{aligned} \tag{4.8}$$

$$n(1+y) : cite : t : `G_{m,n+2}(y) - G_{m+2,n+2}(y)] = (m+n) : cite : t : `G_{m,n}(y) - G_{m+2,n}(y)]$$

$$(m+2) : cite : t : `G_{m+2,n}(y) - G_{m+4,n-2}(y)] = (n-2) : cite : t : `G_{m,n}(y) - G_{m+2,n}(y)]$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", fisher_f(mu, sigma).k_x(t, k))
6.3563523462564525615615615614561356E+00
```

4.8.3 Boost: Student t (Pearson Type VII) distribution

The following functions return the pdf, cdf, qtf or boost class of the Student t distribution with $n > 0$ degrees of freedom and the support interval $(-\infty, +\infty)$.

See also Wikipedia [1173], MathWorld [815], BoostMath [69], Ehrhardt [297] (3.9.29).

`math53.student_t_pdf`(n, x)

Returns pdf(x), the value of the probability density function (*Pdf*) of the Student t distribution:

$$\text{pdf}(x) = \frac{\Gamma((n+1)/2)}{\sqrt{n\pi}\Gamma(n/2)} \left(\frac{n}{n+t^2}\right)^{(n+1)/2}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("StudentTPdf(x, a, b): ", StudentTPdf(x, a, b))
>>> print ("dist_student_t(a, b).pdf(x): ", dist_student_t(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.student_t_cdf`(n, x)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the Student t distribution:

$$\text{cdf}(x) = \begin{cases} 1-p, & x > 0, \\ p & x \le 0. \end{cases}, \quad \text{where } p = \begin{cases} \text{ibeta}(n/2, 1/2, n/(n+x^2))/2, & n < 2x^2, \\ \text{ibetac}(1/2, n/2, x^2/(n+x^2))/2, & n \ge 2x^2. \end{cases}$$

Here ibeta($\cdot$) denotes the real normalised incomplete beta function (*RealIBeta*), and ibetac($\cdot$) denotes the real normalised complementary incomplete beta function (*RealIBetac*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("StudentTCdf(x, a, b): ", StudentTCdf(x, a, b))
>>> print ("dist_student_t(a, b).cdf(x): ", dist_student_t(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.student_t_qtf`(n, q)

where `Ctx` is `Math53` or `CtxBoost`.

Returns qtf(q), the value of the quantile function (*Qtf*) of the Student t distribution:

$$\text{qtf}(q) = t_{\nu,\alpha} = \text{sign}(q-0.5)\sqrt{n(1-x)/x}, \quad \text{where } x = \text{ibeta_inv}\left(\tfrac{1}{2}n, \tfrac{1}{2}, 2\cdot\min(q, 1-q)\right).$$

Here ibeta_inv($\cdot$) denotes the inverse of the real normalised incomplete beta function (*RealIBetaInv*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("StudentTQtf(q, a, b): ", StudentTQtf(q, a, b))
>>> print ("dist_student_t(a, b).qtf(q): ", dist_student_t(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class ctx.**dist_student_t**(n)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The Student t distribution is a continuous probability distribution with $n > 0$ degrees of freedom and the support interval $(-\infty, +\infty)$. See also Wikipedia [1173], MathWorld [815], BoostMath [69], Broda and Paolella [160], Witkovský [1462], Witkovský [1481], R (Statistical System) [528].

See also: https://docs.scipy.org/doc/scipy/reference/generated/scipy.special.stdtrit.html#scipy.special.stdtrit

dist_student_t.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a central Student t distribution:

$$\mathrm{pdf}_X(x) = \frac{\Gamma((n+1)/2)}{\sqrt{n\pi}\Gamma(n/2)} \left(\frac{n}{n+t^2}\right)^{(n+1)/2}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", student_t(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_student_t.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a central Student t distribution:

$$\mathrm{cdf}_X(x) = \begin{cases} 1-p, & x > 0, \\ p & x \le 0. \end{cases}, \quad \text{where } p = \begin{cases} \mathrm{ibeta}(n/2, 1/2, n/(n+x^2))/2, & n < 2x^2, \\ \mathrm{ibetac}(1/2, n/2, x^2/(n+x^2))/2, & n \ge 2x^2. \end{cases}$$

Here $\mathrm{ibeta}(\cdot)$ denotes the real normalised incomplete beta function, and $\mathrm{ibetac}(\cdot)$ denotes the real normalised complementary incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", student_t(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_student_t.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a central Student t distribution:

$$\mathrm{sf}_X(x) = \mathrm{cdf}_X(-x)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", student_t(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_student_t.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a central Student t distribution:

$$\text{qtf}_X(q) = \text{sign}(q-0.5)\sqrt{n(1-x)/x}, \quad \text{where } x = \text{ibeta_inv}\left(\tfrac{1}{2}n, \tfrac{1}{2}, 2\cdot\min(q, 1-q)\right).$$

Here $\text{ibeta_inv}(\cdot)$ denotes the inverse of the real normalised incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", student_t(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_student_t.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a central Student t distribution:

$$\text{isf}_X(q) = -\text{qtf}_X(q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", student_t(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_student_t.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a central Student t distribution:

$$C_X(t) = \frac{K_{n/2}(\sqrt{n}|t|)^{n/2}}{\Gamma(n/2)2^{n/2-1}},$$

where $K_n(\cdot)$ denotes the modified Bessel function of the second kind.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", student_t(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_student_t.**m_x**(t)

Returns `NaN`, since the moment generating function does not exist.

dist_student_t.**k_x**(t, *k=0*)

Returns `NaN`, since the cumulant generating function does not exist.

dist_student_t.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a central Student t distribution. The rth moments only exists for $n_2 > 2r$.

$$\mu'_X(r) = \mu'_t(r) = \left(\tfrac{1}{2}n\right)^{r/2} \frac{\Gamma\left(\frac{1}{2}(n-r)\right)}{\Gamma\left(\frac{1}{2}n\right)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", student_t(mu, sigma).moments(k))
6.356352346256452561561561456l356E+00
```

dist_student_t.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a central Student t distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", student_t(mu, sigma).cumulants(k))
6.356352346256452561561561456l356E+00
```

4.8.4 Distribution of the negative logarithm of a beta variable

class ctx.**dist_logrv_beta**(a, b)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of the negative logarithm of a beta variable with parameters $a > 0$ and $b > 0$ is a continuous probability distribution with the support interval $(0, +\infty)$. See also Wikipedia [1148], MathWorld [797], BoostMath [51], Witkovský [1465], R (Statistical System) [520].

dist_logrv_beta.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of the negative logarithm of a beta variable:

$$\mathrm{pdf}_X(x) = e^{-x} f_{\mathrm{Beta}}(e^{-x}; a, b),$$

where $f_{\mathrm{Beta}}(\cdot, a, b)$ is the pdf of the Beta distribution with parameters a and b.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", fisher_f(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_logrv_beta.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of the negative logarithm of a beta variable:

$$\mathrm{cdf}_X(x) = 1 - F_{\mathrm{Beta}}(e^{-x}; a, b),$$

where $F_{\mathrm{Beta}}(\cdot, a, b)$ is the cdf of the Beta distribution with parameters a and b.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", fisher_f(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_logrv_beta.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following the distribution of the negative logarithm of a beta variable:

$$\mathrm{sf}_X(x) = F_{\mathrm{Beta}}(e^{-x}; a, b),$$

where $F_{\mathrm{Beta}}(\cdot, a, b)$ is the cdf of the Beta distribution with parameters a and b.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_f(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_logrv_beta.**qtf**(q)

Returns $\text{qtf}_X(q)$, the quantile function (qtf) of a random variable X, following the distribution of the negative logarithm of a beta variable:

$$\text{qtf}_X(q) = -\log\left(F^{-1}_{\text{Beta}}(1-q;a,b)\right),$$

where $F^{-1}_{\text{Beta}}(\cdot,a,b)$ is the qtf of the Beta distribution with parameters a and b.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_f(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_logrv_beta.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of the negative logarithm of a beta variable:

$$\text{isf}_X(q) = -\log\left(F^{-1}_{\text{Beta}}(q;a,b)\right),$$

where $F^{-1}_{\text{Beta}}(\cdot,a,b)$ is the qtf of the Beta distribution with parameters a and b.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_logrv_beta.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of the negative logarithm of a beta variable:

$$C_X(t) = \frac{\Gamma\left((a-it)\right)\Gamma\left((a+b)\right)}{\Gamma\left(a\right)\Gamma\left(a+b-it\right)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_logrv_beta.**m_x**(t)

Returns the moment generating function of a random variable X, following the distribution of the negative logarithm of a beta variable.

$$M_X(t) = \frac{\Gamma\left((a-t)\right)\Gamma\left((a+b)\right)}{\Gamma\left(a\right)\Gamma\left(a+b-t\right)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_logrv_beta.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(t), j = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of a beta variable.

$$K_X(t) = \log\left(\Gamma(a-t)\right) - \log\left(\Gamma(a+b-t)\right) + \log\left(\Gamma(a+b)\right) - \log\left(\Gamma(a)\right).$$

$$K_X^{(j)}(t) = (-1)^j \left(\psi^{(j-1)}(a-t) - \psi^{(j-1)}(a+b-t)\right)$$

where $\psi^{(j)}(\cdot)$ is the polygamma function of order j.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_logrv_beta.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of a beta variable. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_logrv_beta.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of a beta variable.

$$\kappa_j = (-1)^j \left(\psi^{(j-1)}(a) - \psi^{(j-1)}(a+b)\right)$$

where $\psi^{(j)}(\cdot)$ is the polygamma function of order j.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

Approximations

ctx.**logrv_beta_ecf_pdf**(*x*, *a*, *b*, *results='cdf'*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Edgeworth approximation to the pdf, cdf and sf.

ctx.**logrv_beta_ecf_qtf**(*q*, *a*, *b*, *results='cdf'*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Cornish-Fisher approximation to the qtf and isf.

4.8.5 Beta-prime (Pearson Type VI) distribution

class ctx.**dist_beta_prime**(a, b)

where ctx is dec, mpm, ipm, fpm, gmp or arb.

The beta-prime distribution is a continuous probability distribution with parameters $a > 0$ and $b > 0$, and the support interval $(0, +\infty)$.

See also Wikipedia [1198], Becker [27].

Pearson Type I: Beta

Pearson Type II: Symmetric Beta

Pearson Type III: Gamma

Pearson Type IV: Extra

Pearson Type V: Inverse Gamma

Pearson Type VI: Beta Prime

Pearson Type VII: Student's t

dist_beta_prime.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a beta-prime distribution:

$$\mathrm{pdf}_X(x) = f(x) = \frac{x^{\alpha-1}(1+x)^{-\alpha-\beta}}{B(\alpha,\beta)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", fisher_f(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_beta_prime.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a beta-prime distribution:

$$\mathrm{cdf}_X(x) = I_{\frac{x}{1+x}}(a,b)$$

Here ibeta$(\cdot)$ denotes the real normalised incomplete beta function, and ibetac$(\cdot)$ denotes the real normalised complementary incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", fisher_f(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_beta_prime.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a beta-prime distribution:

$$\mathrm{sf}_X(x) = 1 - I_{\frac{x}{1+x}}(a,b)$$

Here ibeta$(\cdot)$ denotes the real normalised incomplete beta function, and ibetac$(\cdot)$ denotes the real normalised complementary incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_f(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_beta_prime.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a beta-prime distribution:

$$\text{qtf}_X(q) = ??, \quad \text{where } x = \text{ibeta_inv}(m/2, n/2, q).$$

Here $\text{ibeta_inv}(\cdot)$ denotes the inverse of the real normalised incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_f(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_beta_prime.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a beta-prime distribution:

$$\text{isf}_X(q) = ??, \quad \text{where } x = \text{ibetac_inv}(m/2, n/2, q).$$

Here $\text{ibetac_inv}(\cdot)$ denotes the inverse of the real normalised complementary incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_beta_prime.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a beta-prime distribution:

$$C_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_f(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_beta_prime.**m_x**(t)

Returns `NaN`, since the moment generating function does not exist.

dist_beta_prime.**k_x**(t, *k=0*)

Returns `NaN`, since the cumulant generating function does not exist.

dist_beta_prime.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a beta-prime distribution. For $-\alpha < k < \beta$, the k-th moment is given by

$$\mu'_X(r) = \frac{B(\alpha + k, \beta - k)}{B(\alpha, \beta)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).moments(k))
6.356352346256452561561561561456 1356E+00
```

dist_beta_prime.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a beta-prime distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).cumulants(k))
6.356352346256452561561561561456 1356E+00
```

4.8.6 Generalized Beta (Type 1) distribution

class ctx.**dist_genbeta1**(a, b, p, q)

where ctx is dec, mpm, ipm, fpm, gmp or arb.

The Generalized Beta (Type 1) distribution distribution is a continuous probability distribution with parameters $a > 0$ and $b > 0$, $p > 0$, $q > 0$, and the support interval $(0, +\infty)$.

See also: Kleiber and Kotz [393] (page 230), Wikipedia [1210].

dist_genbeta1.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a Generalized Beta (Type 1) distribution:

$$\mathrm{pdf}_X(x) = \frac{a x^{ap-1}[1-(x/b)^a]^{q-1}}{b^{ap}B(p,q)}, \quad 0 \le x \le b.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", fisher_f(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_genbeta1.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Generalized Beta (Type 1) distribution:

$$\mathrm{cdf}_X(x) = I_z(p,q), \quad \text{where } z = \left(\frac{y}{b}\right)^a, y = \left(\frac{x^a}{1+x^a}\right)^{1/a} \quad x > 0, \quad 0 \le x \le b.$$

See also: Kleiber, page 231

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", fisher_f(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_genbeta1.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a Generalized Beta (Type 1) distribution:

$$\mathrm{sf}_X(x) = 1 - I_z(p,q) = I_{1-z}(p,q), \quad \text{where } z = \left(\frac{y}{b}\right)^a, y = \left(\frac{x^a}{1+x^a}\right)^{1/a} \quad x > 0, \quad 0 \le x \le b.$$

Here ibeta($\cdot$) denotes the real normalised incomplete beta function, and ibetac($\cdot$) denotes the real normalised complementary incomplete beta function. See Kleiber, page 188.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_f(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_genbeta1.**qtf**(*q*)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Generalized Beta (Type 1) distribution:

$$\text{qtf}_X(\text{prob}) = b \cdot z^{1/a}, \quad \text{where } z = \text{ibeta_inv}(p, q, \text{prob}).$$

Here $\text{ibeta_inv}(\cdot)$ denotes the inverse of the real normalised incomplete beta function.

MISSING: transformatio from x to y.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_f(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_genbeta1.**isf**(*q*)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Generalized Beta (Type 1) distribution:

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Generalized Beta (Type 2) distribution:

$$\text{isf}_X(\text{prob}) = b \cdot z^{1/a}, \quad \text{where } z = \text{ibetac_inv}(p, q, \text{prob}).$$

MISSING: transformatio from x to y.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_genbeta1.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Generalized Beta (Type 1) distribution:

$$C_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_f(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_genbeta1.**m_x**(*t*)

Returns `NaN`, since the moment generating function does not exist.

dist_genbeta1.**k_x**(*t*, *k=0*)

Returns `NaN`, since the cumulant generating function does not exist.

dist_genbeta1.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Generalized Beta (Type 1) distribution. The rth moments only exists for $-ap < k < \infty$.

$$\mu'_X(k) = \frac{b^k B(p + k/a, q)}{B(p, q)} = \frac{b^k \Gamma(p + k/a)\Gamma(p + q)}{\Gamma(p + q + k/a)\Gamma(p)},$$

See Kleiber, page 231.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_genbeta1.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a Generalized Beta (Type 1) distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.8.7 Generalized Beta (Type 2) distribution

class ctx.**dist_genbeta2**(a, b, p, q)

where ctx is dec, mpm, ipm, fpm, gmp or arb.

The Generalized Beta (Type 2) distribution distribution is a continuous probability distribution with parameters $a > 0$ and $b > 0$, $p > 0$, $q > 0$, and the support interval $(0, +\infty)$.

See also: Kleiber and Kotz [393] (page 184), Wikipedia [1210].

dist_genbeta2.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a Generalized Beta (Type 2) distribution:

$$\mathrm{pdf}_X(x) = \frac{a x^{ap-1}}{b^{ap} B(p,q)[1 + (x/b)^a]^{p+q}}, \quad x > 0.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; x = 3;
>>> print ("pdf: ", fisher_f(mu, sigma).pdf(x))
6.3563523462564525625625625624562356E-20
```

dist_genbeta2.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Generalized Beta (Type 2) distribution:

$$\mathrm{cdf}_X(x) = I_z(p,q), \quad \text{where } z = \left(\frac{x}{b}\right)^a, \quad x > 0.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; x = 3;
>>> print ("cdf: ", fisher_f(mu, sigma).pdf(x))
6.3563523462564525625625625624562356E-20
```

dist_genbeta2.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a Generalized Beta (Type 2) distribution:

$$\mathrm{sf}_X(x) = 1 - I_z(p,q) = I_{1-z}(p,q), \quad \text{where } z = \left(\frac{x}{b}\right)^a, \quad x > 0.$$

Here ibeta$(\cdot)$ denotes the real normalised incomplete beta function, and ibetac$(\cdot)$ denotes the real normalised complementary incomplete beta function. See Kleiber, page 188.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; x = 3;
>>> print (" sf: ", fisher_f(mu, sigma).pdf(x))
sf: 6.3563523462564525625625625624562356E-20
```

dist_genbeta2.**qtf**(*q*)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Generalized Beta (Type 2) distribution:

$$\text{qtf}_X(\text{prob}) = b \cdot z^{1/a}, \quad \text{where } z = \text{ibeta_inv}(p, q, \text{prob}).$$

Here $\text{ibeta_inv}(\cdot)$ denotes the inverse of the real normalised incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; q = 0.3;
>>> print ("qtf: ", fisher_f(mu, sigma).qtf(q))
qtf: 6.356352346256452562562562562456235 6E+00
```

dist_genbeta2.**isf**(*q*)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Generalized Beta (Type 2) distribution:

$$\text{isf}_X(\text{prob}) = b \cdot z^{1/a}, \quad \text{where } z = \text{ibetac_inv}(p, q, \text{prob}).$$

Here $\text{ibetac_inv}(\cdot)$ denotes the inverse of the real normalised complementary incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.356352346256452562562562562456235 6E+00
```

dist_genbeta2.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Generalized Beta (Type 2) distribution:

$$C_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; t = 0.3;
>>> print ("c_x: ", fisher_f(mu, sigma).c_x(t))
6.356352346256452562562562562456235 6E+00
```

dist_genbeta2.**m_x**(*t*)

Returns `NaN`, since the moment generating function does not exist.

dist_genbeta2.**k_x**(*t*, *k=0*)

Returns `NaN`, since the cumulant generating function does not exist.

dist_genbeta2.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 2 \ldots k$, of a random variable X, following a Generalized Beta (Type 2) distribution. The rth moments only exists for $-ap < k < aq$.

$$\mu'_X(k) = \frac{b^k B(p + k/a, q - k/a)}{B(p, q)} = \frac{b^k \Gamma(p + k/a)\Gamma(q - k/a)}{\Gamma(p)\Gamma(q)},$$

See Kleiber, page 188.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).moments(k))
6.3563523462564525625625625624562356E+00
```

`dist_genbeta2.`**cumulants**`(`k`)`

Returns the first j cumulants, $\kappa_j, j = 2 \ldots k$, of a random variable X, following a Generalized Beta (Type 2) distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).cumulants(k))
6.3563523462564525625625625624562356E+00
```

4.8.8 Generalized logistic distribution (JKB Types I - IV)

class ctx.**dist_genlogistic**(a, b)

where ctx is dec, mpm, ipm, fpm, gmp or arb.

The generalized logistic distribution distribution is a continuous probability distribution with parameters $a > 0$ and $b > 0$, and the support interval $(0, +\infty)$.

See also: Johnson *et al.* [387], Johnson *et al.* [388], Wikipedia [1212].

Type IV is the most general form of the distribution. The Type III distribution can be obtained from Type IV by setting $\beta = \alpha$. The Type II distribution can be obtained from Type IV by setting $\alpha = 1$. The Type I distribution can be obtained from Type IV by setting $\beta = 1$. The logistic distribution is obtained by setting $\alpha = \beta = 1$.

For Type I and Type II, cdf, sf, qtf and isf are availabe in closed form in terms of elementary functions.

For Type III and Type IV, we use the fact that the variable $Z = (\beta/\alpha)\exp(-X)$ has a central F-distribution with $2\alpha, 2\beta$ degrees of freedom (see JKB vol2 2, p.142).

dist_genlogistic.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a generalized logistic (Type IV) distribution:

$$\text{pdf}_X(x) = \frac{1}{B(\alpha,\beta)}\frac{e^{-\beta x}}{(1+e^{-x})^{\alpha+\beta}}, \quad \alpha, \beta > 0.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; x = 3;
>>> print ("pdf: ", fisher_f(mu, sigma).pdf(x))
6.35635234625645256256256256245623 56E-20
```

dist_genlogistic.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a generalized logistic distribution:

$$\text{cdf}_X(x) = \frac{1}{(1+e^{-x})^{\alpha}} \quad \text{for Type I,} \quad \text{and } \text{cdf}_X(x) = 1 - \frac{e^{-\beta x}}{(1+e^{-x})^{\alpha}} \quad \text{for Type II.}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; x = 3;
>>> print ("cdf: ", fisher_f(mu, sigma).pdf(x))
6.35635234625645256256256256245623 56E-20
```

dist_genlogistic.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following a generalized logistic distribution:

The variable $Z = (\beta/\alpha)\exp(-x)$ has a central F-distribution with $2\alpha, 2\beta$ degrees of freedom (see JKB vol2 2, p.142)

$$\text{sf}_X(x) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; x = 3;
>>> print (" sf: ", fisher_f(mu, sigma).pdf(x))
sf: 6.3563523462564525625625625624562356E-20
```

dist_genlogistic.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a generalized logistic distribution:

The variable $Z = (\beta/\alpha)\exp(-x)$ has a central F-distribution with $2\alpha, 2\beta$ degrees of freedom (see JKB vol2 2, p.142)

$$\text{qtf}_X(q) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; q = 0.3;
>>> print ("qtf: ", fisher_f(mu, sigma).qtf(q))
qtf: 6.3563523462564525625625625624562356E+00
```

dist_genlogistic.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a generalized logistic distribution:

The variable $Z = (\beta/\alpha)\exp(-x)$ has a central F-distribution with $2\alpha, 2\beta$ degrees of freedom (see JKB vol2 2, p.142)

$$\text{isf}_X(q) = ??$$

Here $\text{ibetac_inv}(\cdot)$ denotes the inverse of the real normalised complementary incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.3563523462564525625625625624562356E+00
```

dist_genlogistic.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a generalized logistic distribution:

$$C_X(t) = \frac{\Gamma(\beta - it)\Gamma(\alpha + it)}{\Gamma(\alpha)\Gamma(\beta)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; t = 0.3;
>>> print ("c_x: ", fisher_f(mu, sigma).c_x(t))
6.3563523462564525625625625624562356E+00
```

dist_genlogistic.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a generalized logistic distribution:

$$M_X(t) == \frac{\Gamma(\beta - t)\Gamma(\alpha + t)}{\Gamma(\alpha)\Gamma(\beta)}, \quad -\alpha < t < \beta.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).moments(k))
6.35635234625645256256256256245623 56E+00
```

dist_genlogistic.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a generalized logistic distribution:

$$K_X(t) = \log(\Gamma(\beta - t)) + \log(\Gamma(\alpha + t)) - \log(\Gamma(\alpha)) - \log(\Gamma(\beta)), \quad -\alpha < t < \beta.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).moments(k))
6.35635234625645256256256256245623 56E+00
```

dist_genlogistic.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 2 \ldots k$, of a random variable X, following a generalized logistic distribution. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).moments(k))
6.35635234625645256256256256245623 56E+00
```

dist_genlogistic.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 2 \ldots k$, of a random variable X, following a generalized logistic distribution. The cumulants are given by

$$\kappa_X(r) = \psi^{r-1}(\alpha) + (-1)^r \psi^{r-1}(\beta)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).cumulants(k))
6.35635234625645256256256256245623 56E+00
```

4.8.9 Generalized beta-exponential distribution

class ctx.**dist_gen_beta_exp**(a, b)

where ctx is dec, mpm, ipm, fpm, gmp or arb.

The generalized beta-exponential distribution is a continuous probability distribution with parameters $a > 0$ and $b > 0$, and the support interval $(0, +\infty)$.

See also: Wikipedia [1202], Kleiber and Kotz [393] page 184, equ. 6.6, distribution of Y = log(X), Ristić *et al.* [482].

This is the distribution of the generalized logistic distribution, for b = a = 1.

dist_gen_beta_exp.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a generalized beta-exponential distribution:

$$\mathrm{pdf}_X(x) = \frac{ae^{ap(x-\log(b))}}{B(p,q)[1+e^{a(x-\log(b))}]^{p+q}}, \quad -\infty < x < \infty.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", fisher_f(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_gen_beta_exp.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a generalized beta-exponential distribution:

$$\mathrm{cdf}_X(x) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", fisher_f(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_gen_beta_exp.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a generalized beta-exponential distribution:

$$\mathrm{sf}_X(x) = ??$$

Here ibeta($\cdot$) denotes the real normalised incomplete beta function, and ibetac($\cdot$) denotes the real normalised complementary incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_f(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_gen_beta_exp.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a generalized beta-exponential distribution:

$$\text{qtf}_X(q) = ??$$

Here $\text{ibeta_inv}(\cdot)$ denotes the inverse of the real normalised incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_f(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_gen_beta_exp.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a generalized beta-exponential distribution:

$$\text{isf}_X(q) = ??$$

Here $\text{ibetac_inv}(\cdot)$ denotes the inverse of the real normalised complementary incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_gen_beta_exp.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a generalized beta-exponential distribution:

$$C_X(t) = \frac{\Gamma(\beta - it)\Gamma(\alpha + it)}{\Gamma(\alpha)\Gamma(\beta)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_f(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_gen_beta_exp.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a generalized beta-exponential distribution:

$$M_X(t) = b^t \frac{\Gamma(p + t/a)\Gamma(q - t/a)}{\Gamma(p)\Gamma(q)}, \quad -p < t < q.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).moments(k))
6.35635234625645256256256256245623 56E+00
```

dist_gen_beta_exp.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a generalized beta-exponential distribution:

$$K_X(t) = \log(\Gamma(\beta - t)) + \log(\Gamma(\alpha + t)) - \log(\Gamma(\alpha)) - \log(\Gamma(\beta)), \quad -\alpha < t < \beta.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 2; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).moments(k))
6.35635234625645256256256245623 56E+00
```

dist_gen_beta_exp.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 2 \ldots k$, of a random variable X, following a generalized beta-exponential distribution. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_gen_beta_exp.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 2 \ldots k$, of a random variable X, following a generalized beta-exponential distribution. The cumulants are given by

$$\kappa_X(r) = \psi^{r-1}(\alpha) + (-1)^r \psi^{r-1}(\beta)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.8.10 Feller-Pareto distribution

class ctx.**dist_feller_pareto**(a, b)

where ctx is dec, mpm, ipm, fpm, gmp or arb.

The Feller-Pareto distribution is a continuous probability distribution with parameters $a > 0$ and $b > 0$, and the support interval $(0, +\infty)$.

The Feller-Pareto distribution is defined as the distribution of a random variable X with

$$X = \mu + \theta \left(\frac{U}{V}\right)^{1/\gamma}, \quad \gamma, \theta > 0, \mu \in \mathbb{R},$$

where U and V are two independent gamma distributions with shape parameter $\tau > 0$ and $\alpha > 0$, respectively, and common scale parameter 1.

See also: Wikipedia [1204], Dutang *et al.* [295].

For $\mu = \theta, \gamma = \tau = 1$ we obtain the Pareto Type I distribution.

For $\gamma = \tau = 1$ we obtain the Pareto Type II distribution. When $\mu = 0$, we obtain what is generally simply called the Pareto distribution.

For $\alpha = \tau = 1$, we obtain the Pareto Type III distribution.

For $\tau = 1$ we obtain the Pareto Type IV distribution.

For $\mu = 0$, this reduces to the four parameter generalized beta of the second kind distribution (see GB2), with $\text{pdf}_X(x) = f(a, b, p, q)$ (McDonald 1984), where $a = \theta, b = \gamma, p = \tau, q = \alpha$.

dist_feller_pareto.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a Feller-Pareto distribution:

$$\text{pdf}_X(x) = \frac{\gamma \cdot ((x-\mu)/\theta)^{\gamma\tau - 1}}{\theta B(\alpha, \tau)[1 + ((x-\mu)/\theta)^{\gamma}]^{\alpha+\tau}} = \frac{\gamma u^{\tau}(1-u)^{\alpha}}{(x-\mu)B(\alpha,\tau)}, \quad \text{where } u = \frac{y}{1+y}, y = \left(\frac{x-\mu}{\theta}\right)^{\gamma}, \quad x \geq \mu.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", fisher_f(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_feller_pareto.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Feller-Pareto distribution:

$$\text{cdf}_X(x) = I(\tau, \alpha; u), \quad \text{where } u = \frac{y}{1+y}, y = \left(\frac{x-\mu}{\theta}\right)^{\gamma}, \quad x \geq \mu.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", fisher_f(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_feller_pareto.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following a Feller-Pareto distribution:

$$\text{sf}_X(x) = 1 - I(\tau, \alpha; u), \quad \text{where } u = \frac{y}{1+y}, y = \left(\frac{x-\mu}{\theta}\right)^{\gamma}, \quad x \geq \mu.$$

Here $\text{ibeta}(\cdot)$ denotes the real normalised incomplete beta function, and $\text{ibetac}(\cdot)$ denotes the real normalised complementary incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_f(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_feller_pareto.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Feller-Pareto distribution:

$$\text{qtf}_X(q) = ??$$

Here $\text{ibeta_inv}(\cdot)$ denotes the inverse of the real normalised incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_f(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_feller_pareto.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Feller-Pareto distribution:

$$\text{isf}_X(q) = ??$$

Here $\text{ibetac_inv}(\cdot)$ denotes the inverse of the real normalised complementary incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_feller_pareto.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Feller-Pareto distribution:

$$C_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_f(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_feller_pareto.**m_x**(*t*)

Returns NaN, since the moment generating function does not exist.

dist_feller_pareto.**k_x**(*t*, *k=0*)

Returns NaN, since the cumulant generating function does not exist.

dist_feller_pareto.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \dots k$, of a random variable X, following a Feller-Pareto distribution. The kth moments only exists for $k < \alpha\gamma$.

$$\mu'_X(k) = \sum_{j=0}^{k} \binom{k}{j} \frac{\mu^{k-j}\theta^j \Gamma(\tau + j/\gamma)\Gamma(\alpha - j/\gamma)}{\Gamma(\alpha)\Gamma(\tau)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_feller_pareto.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \dots k$, of a random variable X, following a Feller-Pareto distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.8.11 Fisher z distribution

class ctx.**dist_fisher_z**(m, n)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The Fisher z-distribution is a continuous probability distribution with $m > 0$ and $n > 0$ degrees of freedom, and the support interval $(-\infty, +\infty)$. A random variable X follows a Fisher z-distribution with m and n degrees of freedom if it is defined as $X = \frac{1}{2}\log(Y)$, where Y follows a Fisher F-distribution with m and n degrees of freedom. The Fisher z-distribution is always unimodal, asymmetrical if $m \neq n$, and symmetrical if $m = n$. Interchanging m and n is the same as replacing z with $-z$. The mode is at 0.

A Study of R. A. Fisher's z Distribution and the Related F Distribution. Leo A. Aroian. Ann. Math. Statist. 12(4): 429-448 (December, 1941). DOI: 10.1214/aoms/1177731681

dist_fisher_z.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a Fisher z distribution:

$$\text{pdf}_X(x) = 2e^{2x} f_{\text{FisherF}}(e^{2x}; m, n),$$

where $f_{\text{FisherF}}(\cdot, m, n)$ is the pdf of the Fisher F-distribution with m and n degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", fisher_f(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_fisher_z.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Fisher z distribution:

$$\text{cdf}_X(x) = F_{\text{FisherF}}(e^{2x}; m, n),$$

where $F_{\text{FisherF}}(\cdot, m, n)$ is the cdf of the Fisher F-distribution with m and n degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", fisher_f(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_fisher_z.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following a Fisher z distribution:

$$\text{sf}_X(x) = F_{\text{FisherF}}(e^{-2x}; n, m),$$

where $F_{\text{FisherF}}(\cdot, n, m)$ is the cdf of the Fisher F-distribution with n and m degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_f(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

`dist_fisher_z.qtf(`q`)`

Returns $\text{qtf}_X(q)$, the quantile function (qtf) of a random variable X, following a Fisher z distribution:

$$\text{qtf}_X(q) = \tfrac{1}{2}\log\left(F^{-1}_{\text{FisherF}}(q;m,n)\right),$$

where $F^{-1}_{\text{FisherF}}(\cdot,m,n)$ is the qtf of the Fisher F-distribution with m and n degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_f(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

`dist_fisher_z.isf(`q`)`

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Fisher z distribution:

$$\text{isf}_X(q) = -\tfrac{1}{2}\log\left(F^{-1}_{\text{FisherF}}(q;n,m)\right),$$

where $F^{-1}_{\text{FisherF}}(\cdot,n,m)$ is the qtf of the Fisher F-distribution with n and m degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

`dist_fisher_z.c_x(`t`)`

Returns $C_X(t)$, the characteristic function of a random variable X, following a Fisher z distribution:

$$C_X(t) = \left(\frac{n}{m}\right)^{it/2} \frac{\Gamma\left(\frac{1}{2}(n-it)\right)\Gamma\left(\frac{1}{2}(m+it)\right)}{\Gamma\left(\frac{1}{2}n\right)\Gamma\left(\frac{1}{2}m\right)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

`dist_fisher_z.m_x(`t`)`

Returns the moment generating function of a random variable X, following a Fisher z distribution.

$$M_X(t) = \left(\frac{n}{m}\right)^{t/2} \frac{\Gamma\left(\frac{1}{2}(n-t)\right)\Gamma\left(\frac{1}{2}(m+t)\right)}{\Gamma\left(\frac{1}{2}n\right)\Gamma\left(\frac{1}{2}m\right)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_fisher_z.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(t), j = 1 \ldots k$, of a random variable X, following a Fisher z distribution.

$$K_X(t) = \log\left(\Gamma\left(\tfrac{1}{2}(n-t)\right)\right) + \log\left(\Gamma\left(\tfrac{1}{2}(m+t)\right)\right) + \tfrac{1}{2}t\left(\log(n) - \log(m)\right) - \log\left(\Gamma\left(\tfrac{1}{2}n\right)\right) - \log\left(\Gamma\left(\tfrac{1}{2}m\right)\right).$$

$$K_X^{(1)}(t) = \tfrac{1}{2}\left(-\psi^{(0)}\left(\tfrac{1}{2}n - t\right) + \psi^{(0)}\left(\tfrac{1}{2}m + t\right)\right) + \tfrac{1}{2}\left(\log(n) - \log(m)\right),$$

$$K_X^{(j)}(t) = 2^{-j}\left((-1)^j\psi^{(j-1)}\left(\tfrac{1}{2}n - t\right) + \psi^{(j-1)}\left(\tfrac{1}{2}m + t\right)\right), \quad j \geq 2,$$

where $\psi^{(r)}(\cdot)$ is the polygamma function of order r.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_fisher_z.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Fisher z distribution. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_fisher_z.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a Fisher z distribution.

$$\kappa_1 = \tfrac{1}{2}\left(-\psi^{(0)}\left(\tfrac{1}{2}n\right) + \psi^{(0)}\left(\tfrac{1}{2}m\right)\right) + \tfrac{1}{2}\left(\log(n) - \log(m)\right),$$

$$\kappa_r = 2^{-r}\left((-1)^r\psi^{(r-1)}\left(\tfrac{1}{2}n\right) + \psi^{(r-1)}\left(\tfrac{1}{2}m\right)\right), \quad r \geq 2,$$

where $\psi^{(r)}(\cdot)$ is the polygamma function of order r.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

Aroian gives the following approximations for the cumulants, for $n \geq 2, m \geq 2$:

$$\kappa_1 \approx \frac{1}{2}\left(\frac{1}{n} - \frac{1}{m}\right) + \frac{1}{6}\left(\frac{1}{n^2} - \frac{1}{m^2}\right) - \frac{1}{15}\left(\frac{1}{n^4} - \frac{1}{m^4}\right) + \frac{8}{63}\left(\frac{1}{n^6} - \frac{1}{m^6}\right),$$

$$\kappa_r \approx \frac{(r-2)!}{2}\left(\frac{n+r-1}{n^r}+(-1)^r\frac{m+r-1}{m^r}\right)+\frac{r!}{6}\left(\frac{1}{n^{r+1}}+\frac{(-1)^r}{m^{r+1}}\right)-\frac{(r+2)!}{90}\left(\frac{1}{n^{r+3}}+\frac{(-1)^r}{m^{r+3}}\right), \quad r \geq 2.$$

Approximations

`ctx.`**`fisher_z_ecf`**`(`*x*, *m*, *n*, *results='cdf'*`)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Edgeworth approximation to the pdf, cdf and sf.

`ctx.`**`fisher_z_ecf_inv`**`(`*q*, *m*, *n*, *results='qtf'*`)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Cornish-Fisher approximation to the qtf and isf.

`ctx.`**`fisher_z_spa`**`(`*x*, *n*, *results='c'*`)`

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the Luggannini-Rice saddlepoint approximation of the pdf, cdf and sf.

`ctx.`**`fisher_z_spa_inv`**`(`*x*, *n*, *results='qtf'*`)`

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

4.8.12 Skew t-distribution (Jones)

class ctx.**dist_skewt**(a, b)

where ctx is dec, mpm, ipm, fpm, gmp or arb.

The skew-t-distribution is a continuous probability distribution with parameters $a > 0$ and $b > 0$, and the support interval $(-\infty, +\infty)$.

See also: Jones and Faddy [390].

Other skew t-distributions: see downloads.

dist_skewt.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a skew-t-distribution:

$$\mathrm{pdf}_X(x) = \frac{1}{2^{a+b-1}B(a,b)\sqrt{a+b}} \times \left(1 + \frac{x}{\sqrt{a+b+x^2}}\right)^{a+1/2} \times \left(1 - \frac{x}{\sqrt{a+b+x^2}}\right)^{b+1/2}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", fisher_f(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_skewt.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a skew-t-distribution:

$$\mathrm{cdf}_X(x) = I_z(a,b), \quad \text{where } z = \frac{1}{2}\left(1 + \frac{x}{\sqrt{a+b+x^2}}\right)$$

Here ibeta$(\cdot)$ denotes the real normalised incomplete beta function, and ibetac$(\cdot)$ denotes the real normalised complementary incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", fisher_f(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_skewt.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a skew-t-distribution:

$$\mathrm{sf}_X(x) = 1 - I_z(a,b), \quad \text{where } z = \frac{1}{2}\left(1 + \frac{x}{\sqrt{a+b+x^2}}\right)$$

Here ibeta$(\cdot)$ denotes the real normalised incomplete beta function, and ibetac$(\cdot)$ denotes the real normalised complementary incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_f(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_skewt.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a skew-t-distribution:

$$\mathrm{qtf}_X(q) = \frac{\sqrt{a+b}(2Y-1)}{2\sqrt{Y(1-Y)}},$$

where Y is the quantile of the beta distribution. Here $\mathrm{ibeta_inv}(\cdot)$ denotes the inverse of the real normalised incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_f(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_skewt.**isf**(q)

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a skew-t-distribution:

$$\mathrm{isf}_X(q) = \frac{\sqrt{a+b}(2Y-1)}{2\sqrt{Y(1-Y)}},$$

where Y is the quantile of the beta distribution. Here $\mathrm{ibeta_inv}(\cdot)$ denotes the inverse of the real normalised incomplete beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_skewt.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a skew-t-distribution:

$$C_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_f(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_skewt.**m_x**(t)

Returns NaN, since the moment generating function does not exist.

dist_skewt.**k_x**(t, *k=0*)

Returns NaN, since the cumulant generating function does not exist.

dist_skewt.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a skew-t-distribution. The rth moments only exists for $a > r/2$ and $b > r/2$.

$$\mu'_X(r) = \frac{(a+b)^{r/2}}{B(a,b)} \sum_{i=0}^{r} \binom{r}{i} 2^{-i} (-1)^i B\left(a + \frac{r}{2} - i, b - \frac{r}{2}\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).moments(k))
6.35635234625645256156156145613356E+00
```

dist_skewt.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a skew-t-distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f(mu, sigma).cumulants(k))
6.35635234625645256156156145613356E+00
```

4.8.13 Pearson's rho distribution (under H_0)

class ctx.**dist_pearson_rho**(N)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of Pearson's rho (under H_0) with sample size $N \geq 3$, ie. the distribution of the sample correlation coefficient when $\rho = 0$), is a continuous distribution with the support interval $(-1, +1)$.

See also: Wikipedia [1228], Johnson *et al.* [388] page 550.

See also Johnson II, page 550, for characteristic function and mgf.

dist_pearson_rho.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of Pearson's rho (under H_0):

$$\text{pdf}_X(x) = \frac{(1-r^2)^{\frac{N-4}{2}}}{B\left(\frac{1}{2}, \frac{N-2}{2}\right)},$$

where $B(a, b)$ is the beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", pearson_rho(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_pearson_rho.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of Pearson's rho (under H_0):

$$\text{cdf}_X(r) = F_{\text{StudentT}}(t, N-2), \quad \text{where } t = r\sqrt{\frac{N-2}{1-r^2}},$$

and $F_{\text{StudentT}}(t, N-2,)$ is the cdf of the t-distribution with $N-2$ degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", pearson_rho(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_pearson_rho.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following the distribution of Pearson's rho (under H_0):

$$\text{sf}_X(r) = F_{\text{StudentT}}(-t, N-2), \quad \text{where } t = r\sqrt{\frac{N-2}{1-r^2}},$$

and $F_{\text{StudentT}}(t, N-2,)$ is the cdf of the t-distribution with $N-2$ degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", pearson_rho(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_pearson_rho.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following the distribution of Pearson's rho (under H_0):

$$\text{qtf}_X(q) = \frac{t_{\alpha,N-2}}{\sqrt{N-2+t_{\alpha,N-2}^2}},$$

where $t_{\alpha,N-2}$ is the quantile function of the central t-distribution with $N-2$ degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", pearson_rho(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_pearson_rho.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of Pearson's rho (under H_0):

$$\text{isf}_X(q) = \frac{-t_{\alpha,N-2}}{\sqrt{N-2+t_{\alpha,N-2}^2}},$$

where $t_{\alpha,N-2}$ is the quantile function of the central t-distribution with $N-2$ degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", pearson_rho(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_pearson_rho.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of Pearson's rho (under H_0):

$$C_X(t) = \Gamma(\tfrac{1}{2}(N-1)) \cdot 2^{(N-3)/2} \cdot t^{-(N-3)/2} \cdot J_{(N-3)/2}(t),$$

where $J_\nu(t)$ is the Bessel function of the first kind of order ν.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", pearson_rho(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_pearson_rho.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following the distribution of Pearson's rho (under H_0):

$$M_X(t) = \Gamma(\tfrac{1}{2}(N-1)) \cdot 2^{(N-3)/2} \cdot t^{-(N-3)/2} \cdot I_{(N-3)/2}(t),$$

where $I_\nu(t)$ is the modified Bessel function of the second kind of order ν.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", pearson_rho(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_pearson_rho.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following the distribution of Pearson's rho (under H_0):

$$K_X(t) = \log\left(\Gamma(\tfrac{1}{2}(N-1)) \cdot 2^{(N-3)/2} \cdot t^{-(N-3)/2} \cdot I_{(N-3)/2}(t)\right),$$

where $I_\nu(t)$ is the modified Bessel function of the second kind of order ν.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", pearson_rho(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_pearson_rho.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of Pearson's rho (under H_0):

All odd moments are zero. For the even moments we have

$$\mu_X(r) = \tfrac{1}{2} B\left(\tfrac{1}{2}(r+1), \tfrac{1}{2}(N-2)\right)$$

where $B(a, b)$ is the beta function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", pearson_rho(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_pearson_rho.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of Pearson's rho (under H_0). The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", pearson_rho(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.9 Noncentral distributions

4.9.1 Boost: Noncentral χ^2 distribution

The following functions return the pdf, cdf, qtf or boost class of the noncentral chi-squared distribution with degrees of freedom $n > 0$, noncentrality parameter λ_1, and support interval $(0, +\infty)$.

See also Wikipedia [1166], MathWorld [810], Patnaik [465], Penev and Raykov [467], Wang and Gray [795], Winterbottom [1456], BoostMath [64], Johansson [386].

`math53.chi2_nc_pdf`(*n*, *lambda1*, *x*)

Returns pdf(x), the value of the probability density function (*Pdf*) of the noncentral chi-squared distribution:

$$\text{pdf}(x) = f_{\chi^2}(n, x; \lambda_1) = \frac{1}{2} e^{-(x+\lambda)/2} \left(\frac{x}{\lambda}\right)^{k/4-1/2} I_{k/2-1}(\sqrt{\lambda x}) \tag{4.9}$$

where $I_k(y)$ is a modified Bessel function of the first kind of order k.

Alternatively, the pdf can be written in a form which shows the relationship to the central distribution more clearly:

$$\text{pdf}(x) = f_{\chi^2}(n, x; \lambda_1) = f_{\chi^2}(x, n) \times e^{-\lambda_1/2} \times {}_0F_1\left(-; \frac{n}{2}; \frac{x\lambda_1}{4}\right). \tag{4.10}$$

Here $f_{\chi^2}(\cdot)$ is the PDF of the central chi-square distribution, and ${}_0F_1(\cdot)$ is the confluent hypergeometric limit function.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("Chi2NcPdf(x, a, b): ", Chi2NcPdf(x, a, b))
>>> print ("dist_chi_squared_nc(a, b).pdf(x): ", dist_chi_squared_nc(a, b).pdf(x))
6.35635234625645256156156145614561356E+00
```

`math53.chi2_nc_cdf`(*n*, *lambda1*, *x*)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the noncentral chi-squared distribution:

$$\text{cdf}(x) = F_{\chi^2}(n, x; \lambda) = \int_0^x f_{\chi^2}(n, x; \lambda_1)\, \mathrm{d}t.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("Chi2NcCdf(x, a, b): ", Chi2NcCdf(x, a, b))
>>> print ("dist_chi_squared_nc(a, b).cdf(x): ", dist_chi_squared_nc(a, b).cdf(x))
6.35635234625645256156156145614561356E+00
```

`math53.chi2_nc_qtf`(*n*, *lambda1*, *q*)

where `Ctx` is `Math53` or `CtxBoost`.

Returns qtf(q), the value of the quantile function (*Qtf*) of the noncentral chi-squared distribution:

There is no known closed exact form for qtf(q). The default method is to call the function provided by Boost.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("Chi2NcQtf(q, a, b): ", Chi2NcQtf(q, a, b))
>>> print ("dist_chi_squared_nc(a, b).qtf(q): ", dist_chi_squared_nc(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class ctx.**dist_chi2_nc**(*n*, *lambda1*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The noncentral chi-square distribution is a continuous probability distribution with degrees of freedom $n > 0$, noncentrality parameter λ_1, and support interval $(0, \infty)$. See also Wikipedia [1166], MathWorld [810], Patnaik [465], Penev and Raykov [467], Wang and Gray [795], Winterbottom [1456], BoostMath [64], Witkovský [1476], Johansson [386], R (Statistical System) [517], Yu [1500].

dist_chi_squared_nc.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a non-central chi-squared distribution:

$$\text{pdf}_X(x) = f_{\chi^2}(n, x; \lambda) = e^{-\lambda/2} f_{\chi^2}(n, x) {}_0F_1\left(-; \frac{n}{2}; \frac{x\lambda}{4}\right),$$

Here $f_{\chi^2}(\cdot)$ and $F_{\chi^2}(\cdot)$ are the PDF and CDF, respectively, of the central chi-square distribution, and ${}_0F_1(\cdot)$ is the confluent hypergeometric limit function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", chi_squared_nc(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_chi_squared_nc.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a non-central chi-squared distribution:

$$\text{cdf}_X(x) = \int_0^x \text{pdf}_X(x)\mathrm{d}t = F_{\chi^2}(n, x; \lambda) = e^{-\lambda/2} \sum_{j=0}^{\infty} \frac{(\lambda/2)^j}{j!} F_{\chi^2}(n + 2 + j, x),$$

Here $f_{\chi^2}(\cdot)$ and $F_{\chi^2}(\cdot)$ are the PDF and CDF, respectively, of the central chi-square distribution, and ${}_0F_1(\cdot)$ is the confluent hypergeometric limit function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", chi_squared_nc(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_chi_squared_nc.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following a non-central chi-squared distribution:

$$\text{sf}_X(x) = 1 - \text{cdf}_X(x) = \int_x^{\infty} \text{pdf}_X(x)\mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", chi_squared_nc(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_chi_squared_nc.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a non-central chi-squared distribution:

There is no known closed form for the quantile function $\text{cdf}_X^{-1}(q)$: It is computed with Newton iterations where the starting values are from a central chi-square approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", chi_squared_nc(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_chi_squared_nc.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a non-central chi-squared distribution:

$$\text{isf}_X(q) = \text{qtf}_X(1-q) = \text{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", chi_squared_nc(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_chi_squared_nc.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a non-central chi-squared distribution:

$$C_X(t) = \exp\left(\frac{i\lambda t}{1-2it}\right)(1-2it)^{-n/2}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared_nc(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_chi_squared_nc.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a non-central chi-squared distribution:

$$M_X(t) = \exp\left(\frac{\lambda t}{1-2t}\right)(1-2t)^{-n/2}, \quad t \in \left(-\infty, \tfrac{1}{2}\right),$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared_nc(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_chi_squared_nc.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(t), j = 1 \ldots k$, of a random variable X, following a non-central chi-squared distribution:

$$K_X(t) = -\frac{n}{2}\log(1-2t) + \frac{\lambda t}{1-2t}, \quad t \in \left(-\infty, \tfrac{1}{2}\right),$$

$$K_X^{(j)}(t) = \frac{2^{j-1}(j-1)!}{(1-2t)^j}\left[n + \frac{\lambda j}{1-2t}\right].$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", chi_squared_nc(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_chi_squared_nc.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a non-central chi-squared distribution: the moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", chi_squared_nc(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_chi_squared_nc.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a non-central chi-squared distribution:

$$\kappa_r = 2^{r-1}(r-1)!(n + r\lambda)$$

```
def MakeNoncentralChiSquaredCumulants(self):
    df = iv.mpf(2000)
    lambda_ = 33
    k = 10
    kappa = iv.matrix(k+1, 1)
    kappa[0] = 1
    kappa[1] = df + lambda_
    for i in range(2, k+1):
        kappa[i] = kappa[i - 1] * 2 * (i - 1) * (1 + lambda_ / (df + (i - 1) * lambda_))
    return kappa
```

Recurrences: Non-central Chi-square

ctx.**chi_squared_nc_recurrence**(*x*, *n*, *lambda*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The following recurrence relations hold for the pdf and CDF (see Cohen [183]):

$$f_{\chi^2}(n+4, x; \lambda) = \frac{x \cdot f_{\chi^2}(n, x; \lambda) - n \cdot f_{\chi^2}(n+2, x; \lambda)}{\lambda}$$

$$F_{\chi^2}(n, x; \lambda) - F_{\chi^2}(n+2, x; \lambda) = 2 f_{\chi^2}(n+2, x; \lambda)$$

$$F_{\chi^2}(n, x; \lambda) - F_{\chi^2}(n-2, x; \lambda) = 2\frac{\partial}{\partial \lambda} F_{\chi^2}(n-2, x; \lambda)$$

Pav 2015: Moments of log noncentral chisquare

Yu 2011: mode of noncentral chi-square

Approximations

`ctx.chi_squared_nc_gp`(*x*, *n*, *lambda*, *results='cdf'*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the pdf, cdf and sf from the characteristic function using the procedure of Gil-Pelaez (see *gil_pelaez_pdf()* and *gil_pelaez_cdf()*).

`ctx.chi_squared_nc_ecf`(*x*, *f*, *lambda1*, *results='cdf'*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Edgeworth approximation to the pdf, cdf and sf.

`ctx.chi_squared_nc_ecf_inv`(*q*, *f*, *lambda1*, *results='qtf'*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Cornish-Fisher approximation to the qtf and isf.

`ctx.chi_squared_nc_spa`(*x*, *n*, *lambda*, *results='cdf'*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the Luggannini-Rice saddlepoint approximation of the pdf.

The solution $\hat{s}(x)$ of the saddlepoint equation $K_X^{(1)}(\hat{s}(x)) = x$, of a random variable X, following a non-central chi-squared distribution is given by:

$$\hat{s}(x) = -\frac{1}{4x}\left[n - 2x + \sqrt{n^2 + 4x\lambda}\right], \quad x > 0$$

```
def NonCentralChi2_SPA2(self, n0, x0, lambda0_):
    n = iv.mpf(n0)
    x = iv.mpf(x0)
    lambda_ = iv.mpf(lambda0_)
    s = -(1 / (4 * x)) * (n - 2 * x + iv.sqrt(n * n + 4 * x * lambda_))
    Order = 18
    kderiv = iv.matrix(Order+2, 1)
    for j in range(0, Order+1):
        kderiv[j] = self.NonCentralChi2_CGF_Derivative(s, n, lambda_, j)

    LeftTail, RightTail = self.LugannaniRice(Order, kderiv, s)
    return LeftTail, RightTail
```

The following code tests the procedure

```
def LugannaniRiceDemo(self):
    nu = 40.0
    x = 61.0
    nc = 70.0
    LeftTail, RightTail = self.NonCentralChi2_SPA2(nu, x, nc)
    print("LeftTail:  ", LeftTail)
    print("RightTail: ", RightTail)
```

`ctx.chi_squared_nc_spa_inv`(*x*, *n*, *lambda*, *results='qtf'*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

4.9.2 Boost: Noncentral Student t distribution

The following functions return the pdf, cdf, qtf or boost class of the non-central Student t distribution with $n > 0$ degrees of freedom, noncentrality parameter δ, and support interval $(-\infty, +\infty)$.

See also Wikipedia [1167], MathWorld [812], BoostMath [66], Benton and Krishnamoorthy [30], Broda and Paolella [160], Owen [455], Wang and Gray [795], Witkovský [1463], Johansson [386].

`math53.`**`student_t_nc_pdf`**(*n*, *delta*, *x*)

Returns pdf(x), the value of the probability density function (*Pdf*) of the non-central Student t distribution:

$$\text{pdf}(x) = f_{\text{StudentT}}(n, x, \delta) = \int_0^\infty \phi\left(x\sqrt{\frac{y}{n}} - \delta\right) f_{\chi^2}(y, n)\sqrt{\frac{y}{n}}\,\mathrm{d}y, \tag{4.11}$$

where $\phi(\cdot)$ denotes the pdf of the standard normal distribution and $f_{\chi^2}(\cdot, n)$ denotes the pdf of the χ^2 distribution with n degrees of freedom (see *chi_squared_pdf()*).

Alternatively, the pdf can be written in a form which shows the relationship to the central distribution more clearly:

$$\text{pdf}(x) = f_{t'}(x; n, \delta) = \frac{n^m \Gamma(n+1)\exp(-\frac{1}{2}\delta^2)}{2^n a^m \Gamma(m)}\left[\frac{\sqrt{2}\delta x \cdot {}_1F_1(m+1; \frac{3}{2}; y^2)}{a\Gamma(m+\frac{1}{2})} - \frac{{}_1F_1(m+\frac{1}{2}; \frac{1}{2}; y^2)}{\sqrt{a}\Gamma(m+1)}\right], \tag{4.12}$$

$$m = \frac{n}{2}, \quad a = n + x^2, \quad y^2 = \frac{\delta^2 x^2}{2a},$$

and ${}_1F_1(\cdot)$ is the confluent hypergeometric function.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("StudentTNcPdf(x, a, b): ", StudentTNcPdf(x, a, b))
>>> print ("dist_student_t_nc(a, b).pdf(x): ", dist_student_t_nc(a, b).pdf(x))
6.35635234625645256156156145614561356E+00
```

`math53.`**`student_t_nc_cdf`**(*n*, *delta*, *x*)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the non-central Student t distribution:

$$\text{cdf}(x) = F_{\text{StudentT}}(x, n, \delta) = \int_0^\infty \Phi\left(x\sqrt{\frac{y}{n}} - \delta\right) f_{\chi^2}(y, n)\,\mathrm{d}y, \tag{4.13}$$

for $x < 0$ by $F_{\text{StudentT}}(n, x, \delta) = 1 - F_{\text{StudentT}}(n, -x, -\delta)$, and for $x = 0$ by $F_{\text{StudentT}}(n, x, \delta) = \Phi(-\delta)$.

Here $\Phi(\cdot)$ denotes the cdf of the standard normal distribution and $f_{\chi^2}(\cdot, n)$ denotes the pdf of the χ^2 distribution with n degrees of freedom.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("StudentTNcCdf(x, a, b): ", StudentTNcCdf(x, a, b))
>>> print ("dist_student_t_nc(a, b).cdf(x): ", dist_student_t_nc(a, b).cdf(x))
6.35635234625645256156156145614561356E+00
```

math53.**student_t_nc_qtf**(*n*, *delta*, *q*)

Returns qtf(q), the value of the quantile function (*Qtf*) of the non-central Student t distribution:

There is no known closed exact form for qtf(q). For `fpm.` the default method is to call the function provided by Boost.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("StudentTNcQtf(q, a, b): ", StudentTNcQtf(q, a, b))
>>> print ("dist_student_t_nc(a, b).qtf(q): ", dist_student_t_nc(a, b).qtf(q))
6.3563523462564525615615615614561356E+00
```

class ctx.**dist_student_t_nc**(*n*, *lambda1*)

The noncentral t distribution is a continuous probability distribution with degrees of freedom $n > 0$, noncentrality parameter δ, and support interval $(-\infty, +\infty)$. See also Wikipedia [1167], MathWorld [812], BoostMath [66], Benton and Krishnamoorthy [30], Broda and Paolella [160], Owen [455], Wang and Gray [795], Witkovský [1463], Johansson [386], R (Statistical System) [519].

Ref: Kim (2007), CI noncentrality parameters

Application: Scholz.

Young, R package tolerance intervals

dist_student_t_nc.**pdf**(*x*)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a non-central Student t distribution:

$$\text{pdf}_X(x) = f_{t'}(x; n, \delta) = \frac{n^m \Gamma(n+1) \exp(-\frac{1}{2}\delta^2)}{2^n a^m \Gamma(m)} \left[\frac{\sqrt{2}\delta x \cdot {}_1F_1(m+1; \frac{3}{2}; y^2)}{a\Gamma(m+\frac{1}{2})} - \frac{{}_1F_1(m+\frac{1}{2}; \frac{1}{2}; y^2)}{\sqrt{a}\Gamma(m+1)} \right],$$

$$m = \frac{n}{2}, \quad a = n + x^2, \quad y^2 = \frac{\delta^2 x^2}{2a},$$

and ${}_1F_1(\cdot)$ is the confluent hypergeometric function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", student_t_nc(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_student_t_nc.**cdf**(*x*)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a non-central Student t distribution:

$$\text{cdf}_X(x) = F_{t'}(x; n, \delta) = \int_0^x f_t(x; n, \delta) \mathrm{d}t = \Phi(-\delta) + \frac{1}{2} \sum_{i=0}^{\infty} P_i I_z\left(i + \tfrac{1}{2}, m\right) + \frac{\delta}{\sqrt{2}} Q_i I_z\left(i + 1, m\right),$$

$$P_i = \frac{e^{-\lambda}\lambda^i}{i!}, \quad Q_i = \frac{e^{-\lambda}\lambda^i}{\Gamma(i+3/2)}; \quad z = \frac{t^2}{n+t^2},$$

and $I_x(\cdot,\cdot)$ denotes the (normalized) incomplete beta function , and $\Phi(\cdot)$ denotes the CDF of the normal distribution.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", student_t_nc(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

`dist_student_t_nc.`**`sf`**`(`x`)`

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a non-central Student t distribution:

$$\mathrm{sf}_X(x) = 1 - \mathrm{cdf}_X(x) = \int_x^\infty \mathrm{pdf}_X(x)\mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", student_t_nc(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

`dist_student_t_nc.`**`qtf`**`(`q`)`

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a non-central Student t distribution:

There is no known explicit form for the quantile function $\mathrm{cdf}_X^{-1}(x)$: It is computed using Newton iterations with starting values from a normal approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", student_t_nc(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

`dist_student_t_nc.`**`isf`**`(`q`)`

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a non-central Student t distribution:

$$\mathrm{isf}_X(q) = \mathrm{qtf}_X(1-q) = \mathrm{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", student_t_nc(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

`dist_student_t_nc.`**`c_x`**`(`t`)`

Returns $C_X(t)$, the characteristic function of a random variable X, following a non-central Student t distribution:

$$C_X(t) = \int_{-\infty}^{\infty} e^{itx}\mathrm{pdf}_X(x)\mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", student_t_nc(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_student_t_nc.**m_x**(*t*)

Returns NaN, since the moment generating function does not exist.

dist_student_t_nc.**k_x**(*t*, *k=0*)

Returns NaN, since the cumulant generating function does not exist.

dist_student_t_nc.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a non-central Student t distribution. The rth moment only exists for $n > r$. and is given by

$$\mu'_X(r) = \left(\tfrac{1}{2}n\right)^{r/2} \frac{\Gamma\left(\frac{1}{2}(n-r)\right)}{\Gamma\left(\frac{1}{2}n\right)} \times \sum_{i=0}^{\lfloor r/2 \rfloor} \binom{r}{2i} \frac{(2i)!}{2^i i!} \delta^{r-2i},$$

See also: Paoella 2, page 381-382

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", student_t_nc(mu, sigma).moments(k))
6.3563523462564525615615615614561356E+00
```

dist_student_t_nc.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a non-central Student t distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", student_t_nc(mu, sigma).cumulants(k))
6.3563523462564525615615615614561356E+00
```

Approximations

ctx.**student_t_nc_ecf**(*x*, *n*, *delta*, *results='cdf'*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Edgeworth approximation to the pdf, cdf and sf. See also: Paolella [457], page 381-382.

ctx.**student_t_nc_ecf_inv**(*q*, *n*, *delta*, *theta*, *results='qtf'*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Cornish-Fisher approximation to the qtf and isf.

4.9.3 Boost: Noncentral Fisher F distribution

The following functions return the pdf, cdf, qtf or boost class of the non-central Fisher F distribution with $m > 0$ and $n > 0$ degrees of freedom, noncentrality parameter λ_1 , and the support interval $(0, +\infty)$.

See also Wikipedia [1164], MathWorld [811], BoostMath [65], Benton and Krishnamoorthy [30], Butler and Paolella [166], Chou [179], Chattamvelli and Jones [175], Wang and Gray [795], Johansson [386].

`math53.`**`fisher_f_nc_pdf`**(*m*, *n*, *lambda1*, *x*)

Returns pdf(x), the value of the probability density function (*Pdf*) of the non-central Fisher F distribution:

$$\text{pdf}(x) = f_{\text{FisherF}}(x; m, n; \lambda_1) = \frac{m}{n} \int_0^\infty y \cdot f_{\chi^2}\left(x \cdot y \cdot m/n, m, \lambda_1\right) \cdot f_{\chi^2}(y, n)\, \mathrm{d}y \tag{4.14}$$

Here $f_{\chi^2}(\cdot, m, \lambda_1)$ denotes the pdf of the noncentral χ^2 distribution with m degrees of freedom and noncentrality parameter λ_1 (see *chi2_nc_pdf()*), and $f_{\chi^2}(\cdot, n)$ denotes the pdf of the central χ^2 distribution with n degrees of freedom (see *chi_squared_pdf()*).

Alternatively, the pdf can be written in a form which shows the relationship to the central distribution more clearly:

$$\text{pdf}(x) = f_{F'}(x; n_1, n_2, \lambda_1) = e^{-\lambda_1/2} f_F(x; n_1, n_2) {}_1F_1\left(\tfrac{1}{2}(m+n), \tfrac{1}{2}n, \tfrac{nx\lambda_1}{2(m+nx)}\right), \tag{4.15}$$

Here $f_F(\cdot)$ denotes the pdf of the central F-distribution, and ${}_1F_1(\cdot)$ is the confluent hypergeometric function.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("FisherFNcPdf(x, a, b): ", FisherFNcPdf(x, a, b))
>>> print ("dist_fisher_f_nc(a, b).pdf(x): ", dist_fisher_f_nc(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`fisher_f_nc_cdf`**(*m*, *n*, *lambda1*, *x*)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the non-central Fisher F distribution:

$$\text{cdf}(x) = F_{\text{FisherF}}(x; m, n; \lambda_1) = \frac{mx}{n} \int_0^\infty f_{\chi^2}\left(x \cdot y \cdot m/n, m; \lambda_1\right) \cdot \left[1 - F_{\chi^2}(y, n)\right] \mathrm{d}y \tag{4.16}$$

Here $f_{\chi^2}(\cdot, m, \lambda_1)$ denotes the pdf of the noncentral χ^2 distribution with m degrees of freedom and noncentrality parameter λ_1 (see *chi2_nc_pdf()*), and $F_{\chi^2}(\cdot, n)$ denotes the cdf of the central χ^2 distribution with n degrees of freedom (see *chi_squared_cdf()*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("FisherFNcCdf(x, a, b): ", FisherFNcCdf(x, a, b))
>>> print ("dist_fisher_f_nc(a, b).cdf(x): ", dist_fisher_f_nc(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`fisher_f_nc_qtf`**(*m*, *n*, *lambda1*, *q*)

Returns qtf(q), the value of the quantile function (*Qtf*) of the non-central Fisher F distribution:

There is no known closed exact form for qtf(q). For `fpm.` the default method is to call the function provided by Boost.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("FisherFNcQtf(q, a, b): ", FisherFNcQtf(q, a, b))
>>> print ("dist_fisher_f_nc(a, b).qtf(q): ", dist_fisher_f_nc(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class ctx.**dist_fisher_f_nc**(*m*, *n*, *lambda1*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The non-central Fisher F distribution is a continuous probability distribution with $m > 0$ and $n > 0$ degrees of freedom, noncentrality parameter λ_1 , and the support interval $(0, +\infty)$. See also Wikipedia [1164], MathWorld [811], BoostMath [65], Benton and Krishnamoorthy [30], Butler and Paolella [166], Chou [179], Chattamvelli and Jones [175], Wang and Gray [795], Witkovský [1477], Johansson [386], R (Statistical System) [518]. Also doubly-noncentral: Yin [1499].

See also: https://docs.scipy.org/doc/scipy/reference/generated/scipy.special.ncfdtrinc.html#scipy.special.ncfdtrinc

dist_fisher_f_nc.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a non-central Fisher F distribution:

$$\text{pdf}_X(x) = f_{F'}(x; n_1, n_2, \lambda) = e^{-\lambda/2} f_F(x; n_1, n_2)\, {}_1F_1\left(\tfrac{1}{2}(m+n), \tfrac{1}{2}n, \tfrac{nx\lambda}{2(m+nx)}\right),$$

Here $f_F(\cdot)$ denotes the pdf of the central F-distribution, and ${}_1F_1(\cdot)$ is the confluent hypergeometric function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", fisher_f_nc(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_fisher_f_nc.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a non-central Fisher F distribution:

$$\text{cdf}_X(x) = F_{F'}(x; m, n, \lambda) = e^{-\lambda} \sum_{j=0}^{\infty} \frac{(\lambda/2)^j}{j!} F_F(x; m+2j, n)$$

Here $F_F(\cdot)$ denotes the cdf of the central F-distribution.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", fisher_f_nc(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_fisher_f_nc.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a non-central Fisher F distribution:

$$\mathrm{sf}_X(x) = 1 - \mathrm{cdf}_X(x) = \int_x^\infty \mathrm{pdf}_X(x)\mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_f_nc(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_fisher_f_nc.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a non-central Fisher F distribution:

There is no known explicit form for the quantile function $\mathrm{cdf}_X^{-1}(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_f_nc(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_fisher_f_nc.**isf**(q)

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a non-central Fisher F distribution:

$$\mathrm{isf}_X(q) = \mathrm{qtf}_X(1-q) = \mathrm{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f_nc(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_fisher_f_nc.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a non-central Fisher F distribution:

$$C_X(t) = \int_0^\infty e^{itx}\mathrm{pdf}_X(x)\mathrm{d}x$$

$$\phi(t) = e^{-\lambda/2}\sum_{k=0}^{\infty}\frac{(\lambda/2)^k}{k!}{}_1F_1\left(\frac{\nu_1}{2}+k, -\frac{\nu_2}{2}, -\frac{\nu_2}{\nu_1}it\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_f_nc(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_fisher_f_nc.**m_x**(*t*)

Returns NaN, since the moment generating function does not exist.

dist_fisher_f_nc.**k_x**(*t*, *k=0*)

Returns NaN, since the cumulant generating function does not exist.

dist_fisher_f_nc.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \dots k$, of a random variable X, following a non-central Fisher F distribution. The rth moment only exists for $n_2 > 2r$ and is given by

$$\mu'_X(r) = \left(\frac{n_2}{n_1}\right)^r \frac{\Gamma(\frac{1}{2}n_1 + r)\Gamma(\frac{1}{2}n_2 - r)}{\Gamma(\frac{1}{2}n_2)} {}_1\widetilde{F}_1(-r; \tfrac{1}{2}n_1; -\tfrac{1}{2}\lambda_1),$$

where ${}_1\widetilde{F}_1(a, b; z)$ denotes Kummer's regularized confluent hypergeometric function.

See also: Paoella 2, page 358-360

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f_nc(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_fisher_f_nc.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \dots k$, of a random variable X, following a non-central Fisher F distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_f_nc(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

Additional methods: Confidence intervals and sample size estimates

dist_fisher_f_nc.**nc_ci**(*alpha*, *beta*)

Returns a confidence interval for the noncentrality parameter *lambda*

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", fisher_f_nc(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

Recurrences: Non-central Fisher F, recurrence pdf

ctx.**fisher_f_nc_pdf_recurrence**(*x*, *lambda*, *start_n1*, *start_n2*, *target_n1*, *target_n2*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The following recurrence relations hold for the pdf:

Let the density $g_{m,n}$ be that of m/n times an $F_{m,n}$ random variable. Let $G_{m,n}(y)$ be its distribution function, and let $g^{\lambda}_{m,n}$ and $G^{\lambda}_{m,n}(y)$ be the density and distribution function of its (singly) noncentral version (the distribution of $\chi^2_m(\lambda)/\chi^2_n(0)$). Then the following recurrence relations hold (see Chattamvelli and Jones [175])

Applies a recurrence relation to calculate the cdf for different degrees of freedom for a given value of *x*. This is mostly useful when using asymptotic methods.

$$n\left[G^{\lambda}_{m,n+2}(y) - G^{\lambda}_{m-2,n+2}(y)\right] = -2g^{\lambda}_{m,n}(y)$$

$$\lambda(1+y)g^{\lambda}_{m+4,n}(y) = [\lambda y - m(1+y)]g^{\lambda}_{m+2,n}(y) + y(m+n)g^{\lambda}_{m,n}(y).$$

$$n(1+y)g^{\lambda}_{m,n+2}(y) = (m+n)g^{\lambda}_{m,n}(y) + \lambda g^{\lambda}_{m+2,n}(y).$$

$$\lambda g^{\lambda}_{m+4,n-2}(y) + m g^{\lambda}_{m+2,n-2}(y) = (n-2)y g^{\lambda}_{m,n}(y).$$

Recurrences: Non-central Fisher F, recurrence cdf

`ctx.`**`fisher_f_nc_cdf_recurrence`**(*x*, *lambda*, *start_n1*, *start_n2*, *target_n1*, *target_n2*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Applies a recurrence relation to calculate the cdf for different degrees of freedom for a given value of *x*. This is mostly useful when using asymptotic methods.

From these equations we obtain

$$\begin{aligned} \lambda(1+y)G^{\lambda}_{m+6,n}(y) &= [\lambda y - (m+2-\lambda)(1+y)]G^{\lambda}_{m+4,n}(y) \\ &+ [(m+2)(1+y) + y(m+n-\lambda)]G^{\lambda}_{m+2,n}(y) \\ &- y(m+n)G^{\lambda}_{m,n}(y) \end{aligned} \tag{4.17}$$

$$\begin{aligned} n(1+y) : cite : t : `G^{\lambda}_{m,n+2}(y) - G^{\lambda}_{m+2,n+2}(y)] &= (m+n)G^{\lambda}_{m,n}(y) \\ &+ (\lambda - m - n)G^{\lambda}_{m+2,n}(y) \\ &- \lambda G^{\lambda}_{m+4,n}(y) \end{aligned} \tag{4.18}$$

$$\begin{aligned} (n-2)y : cite : t : `G^{\lambda}_{m,n}(y) - G^{\lambda}_{m+2,n}(y)] &= (m+2)G^{\lambda}_{m+2,n-2}(y) \\ &+ (\lambda - m - 2)G^{\lambda}_{m+4,n-2}(y) \\ &- \lambda G^{\lambda}_{m+6,n-2}(y) \end{aligned} \tag{4.19}$$

Approximations

`ctx.`**`fisher_f_nc_ecf`**(*x*, *m*, *n*, *lambda1*, *results='cdf'*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Edgeworth approximation to the pdf, cdf and sf. See also: MathWorld [811], Paolella [457], page 358-360.

`ctx.`**`fisher_f_nc_ecf_inv`**(*q*, *m*, *n*, *lambda1 results='qtf'*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Cornish-Fisher approximation to the qtf and isf.

4.9.4 Boost: Noncentral Beta Type I distribution

The following functions return pdf, cdf, qtf or boost class of the noncentral beta distribution with shape parameters a and b, noncentrality parameter λ_1 and the support interval $(0, 1)$.

See also Wikipedia [1165], BoostMath [63], Wang and Gray [795], Johansson [386].

`math53.beta_nc_pdf`(*a*, *b*, *lambda1*, *x*)

Returns pdf(x), the value of the probability density function (*Pdf*) of the noncentral beta distribution:

$$\text{pdf}(x) = f_{\text{Beta}}(x; a, b; \lambda_1) = \frac{a}{b} \int_0^\infty y \cdot f_{\chi^2}\left(x \cdot y \cdot a/b, 2a, \lambda_1\right) \cdot f_{\chi^2}(y, n)\, \mathrm{d}y \tag{4.20}$$

Here $f_{\chi^2}(\cdot, m, \lambda_1)$ denotes the pdf of the noncentral χ^2 distribution with m degrees of freedom and noncentrality parameter λ_1 (see *chi2_nc_pdf()*), and $f_{\chi^2}(\cdot, n)$ denotes the pdf of the central χ^2 distribution with n degrees of freedom (see *chi_squared_pdf()*).

Alternatively, the pdf can be written in a form which shows the relationship to the central distribution more clearly:

$$\text{pdf}(x) = f_{\text{Beta}'}(x; a, b, \lambda_1) = e^{-\lambda_1/2} f_{\text{Beta}}(x; a, b) \times {}_1F_1\left((a+b), b, \tfrac{nx\lambda_1}{2(m+nx)}\right) \tag{4.21}$$

and $f_{\text{Beta}}(\cdot)$ denotes the PDF of the central Beta-distribution, and ${}_1F_1(\cdot)$ is the confluent hypergeometric function.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("BetaNcPdf(x, a, b): ", BetaNcPdf(x, a, b))
>>> print ("dist_beta_nc(a, b).pdf(x): ", dist_beta_nc(a, b).pdf(x))
6.35635234625645256156156145613356E+00
```

`math53.beta_nc_cdf`(*a*, *b*, *lambda1*, *x*)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the noncentral beta distribution:

$$\text{cdf}(x) = F_{\text{Beta}}(x; a, b; \lambda_1) = \frac{az}{b} \int_0^\infty f_{\chi^2}\left(z \cdot y \cdot a/b, 2a; \lambda_1\right) \cdot \left[1 - F_{\chi^2}(y, 2b)\right] \mathrm{d}y, \quad z = \frac{bx}{a(1-x)} \tag{4.22}$$

Here $f_{\chi^2}(\cdot, m, \lambda_1)$ denotes the pdf of the noncentral χ^2 distribution with m degrees of freedom and noncentrality parameter λ_1 (see *chi2_nc_pdf()*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("BetaNcCdf(x, a, b): ", BetaNcCdf(x, a, b))
>>> print ("dist_beta_nc(a, b).cdf(x): ", dist_beta_nc(a, b).cdf(x))
6.35635234625645256156156145613356E+00
```

`math53.beta_nc_qtf`(*a*, *b*, *lambda1*, *q*)

Returns qtf(q), the value of the quantile function (*Qtf*) of the noncentral beta distribution:

There is no known closed exact form for qtf(q). For `fpm.` the default method is to call the function provided by Boost.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("BetaNcQtf(q, a, b): ", BetaNcQtf(q, a, b))
>>> print ("dist_beta_nc(a, b).qtf(q): ", dist_beta_nc(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class ctx.dist_beta_nc_type_I(*a*, *b*, *lambda1*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The noncentral Beta Type I distribution is a continuous probability distribution with shape parameters a and b, noncentrality parameter λ_1 and the support interval $(0, 1)$. See also Wikipedia [1165], MathWorld [245], BoostMath [63], Wang and Gray [795], Witkovský [1475], Johansson [386], R (Statistical System) [516].

A random variable X follows a Type I noncentral beta distribution with shape parameters a and b and noncentrality parameter λ, if it is defined as $X = U_1/(U_1 + U_2)$ where U_1 and U_2 are independent with $U_1 \sim \chi^2(n_1, \lambda)$, and $U_2 \sim \chi^2(n_2)$ $n_1 = 2a$ and $n_2 = 2b$ are the degrees of freedom, and λ is the noncentrality parameter of the noncentral χ^2 distribution. The random variable $Y = 1 - X$ is said to follow a Type II noncentral beta distribution with shape parameters a and b and noncentrality parameter λ.

dist_beta_nc_type_I.pdf(*x*)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a Type I noncentral beta distribution:

$$\mathrm{pdf}_X(x) = f_{\mathrm{Beta}'}(x; a, b, \lambda) = e^{-\lambda/2} f_{\mathrm{Beta}}(x; a, b) \times {}_1F_1\left((a+b), b, \tfrac{nx\lambda}{2(m+nx)}\right)$$

and $f_{\mathrm{Beta}}(\cdot)$ and $F_{\mathrm{Beta}}(\cdot)$ denote the PDF and CDF, respectively, of the central Beta-distribution, and ${}_1F_1(\cdot)$ is the confluent hypergeometric function. There is no known explicit form for the quantile function $\mathrm{cdf}_X^{-1}(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", beta_nc_type_I(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_beta_nc_type_I.cdf(*x*)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Type I noncentral beta distribution:

$$\mathrm{cdf}_X(x) = F_{\mathrm{Beta}'}(x; a, b, \lambda) = \int_0^x f_{\mathrm{Beta}'}(x; a, b, \lambda)\mathrm{d}t = e^{-\lambda/2} \sum_{j=0}^{\infty} \frac{(\lambda/2)^j}{j!} F_{\mathrm{Beta}}(x; a+j, b)$$

and $f_{\mathrm{Beta}}(\cdot)$ and $F_{\mathrm{Beta}}(\cdot)$ denote the PDF and CDF, respectively, of the central Beta-distribution, and ${}_1F_1(\cdot)$ is the confluent hypergeometric function. There is no known explicit form for the quantile function $\mathrm{cdf}_X^{-1}(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", beta_nc_type_I(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_beta_nc_type_I.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a Type I noncentral beta distribution:

$$\mathrm{sf}_X(x) = 1 - \mathrm{cdf}_X(x) = \int_x^1 \mathrm{pdf}_X(x)\mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", beta_nc_type_I(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_beta_nc_type_I.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Type I noncentral beta distribution:

There is no known closed form for the quantile function $\mathrm{cdf}_X^{-1}(q)$: It is computed with Newton iterations where the starting values are from a approximation by Winterbottom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", beta_nc_type_I(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_beta_nc_type_I.**isf**(q)

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Type I noncentral beta distribution:

$$\mathrm{isf}_X(q) = \mathrm{qtf}_X(1-q) = \mathrm{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", beta_nc_type_I(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_beta_nc_type_I.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Type I noncentral beta distribution:

$$C_X(t) = \int_0^1 e^{itx}\mathrm{pdf}_X(x)\mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", beta_nc_type_I(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_beta_nc_type_I.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a Type I noncentral beta distribution:

$$M_X(t) = \int_0^1 e^{tx}\mathrm{pdf}_X(x)\mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", beta_nc_type_I(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_beta_nc_type_I.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function:

$$K_X(t) = \log(M_X(t))$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", beta_nc_type_I(mu, sigma).k_x(t, k))
6.3563523462564525615615615614561356E+00
```

dist_beta_nc_type_I.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Type I noncentral beta distribution: the moments are calculated from their definition:

$$\mu'_X(r) = E(X^r) = \int_0^1 x^r \text{pdf}_X(x)\text{d}x$$

Returns the raw moments of non-central beta function. See Walck for details.

Algebraic moments of the non-central Beta-distribution are given as (see cite{walck_2007}, p. 109)

$$\text{E}(x^k) = e^{-\lambda/2} \sum_{r=0}^{\infty} \frac{(\lambda/2)^r}{r!} \frac{B(p+r+k, q)}{B(p+r, q)}$$

$$\text{E}(x^k) = \frac{\Gamma(p+k)\Gamma(p+q)}{\Gamma(p)\Gamma(p+q+k)} \times e^{-\lambda/2}{}_2F_2 1(p+q, p+k; p, p+q+k; \lambda/2)$$

Lower order moments are given by

$$\text{E}(Y) = \frac{a}{a+b} \times e^{-\lambda/2}{}_2F_2(a+1, a+b; a, a+b+1; \lambda/2)$$

$$\text{E}(Y^2) = \frac{a(a+1)}{a+b(a+b+1)} \times e^{-\lambda/2}{}_2F_2(a+1, a+b; a, a+b+1; \lambda/2)$$

The moments of $Y = 1 - X$ are given by:

$$\mu'_Y(r) = \frac{\Gamma(n/2+r)\Gamma((n+m)/2)}{\Gamma(n/2)\Gamma((n+m)/2+r)} \times {}_1F_1\left(r; \frac{n+m}{2} + r; -\frac{1}{2}\lambda\right),$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", beta_nc_type_I(mu, sigma).moments(k))
6.3563523462564525615615615614561356E+00
```

dist_beta_nc_type_I.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a Type I noncentral beta distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", beta_nc_type_I(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.9.5 Noncentral Chi distribution

class ctx.**dist_chi_nc**(*n1*, *n2*, *lambda*, ***kwargs*)

These functions return PDF, CDF, and ICDF of the noncentral chi distribution with location a, scale $b > 0$, and the support interval $(-\infty, +\infty)$:

See also: Wikipedia [1218], Witkovský [1493].

dist_chi_nc.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an noncentral chi distribution:

$$\text{pdf}_X(x) = \frac{e^{-(x^2+\lambda^2)/2} x^k \lambda}{(\lambda x)^{k/2}} I_{k/2-1}(\lambda x)$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", dist_chi_nc(mu, sigma).pdf(x))
6.356352346256452561561561561456 1356E-20
```

dist_chi_nc.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an noncentral chi distribution:

$$\text{cdf}_X(x) = 1 - Q_{\frac{k}{2}}(\lambda, x)$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", dist_chi_nc(mu, sigma).pdf(x))
6.356352346256452561561561561456 1356E-20
```

dist_chi_nc.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function function (sf) of a random variable X, following an noncentral chi distribution:

$$\text{sf}_X(x) = 1 - \text{cdf}_X(x).$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", dist_chi_nc(mu, sigma).pdf(x))
sf: 6.356352346256452561561561561456 1356E-20
```

dist_chi_nc.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an noncentral chi distribution:

$$\text{qtf}_X(q) = ??$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", dist_chi_nc(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_chi_nc.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following an noncentral chi distribution:

$$\text{isf}_X(q) = ??$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", dist_chi_nc(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_chi_nc.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an noncentral chi distribution:

$$C_X(t) = ??$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_chi_nc(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_chi_nc.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following an noncentral chi distribution:

$$M_X(t) = ??$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", dist_chi_nc(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_chi_nc.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an noncentral chi distribution:

$$K_X(t) = ??$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", dist_chi_nc(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_chi_nc.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an noncentral chi distribution (Wikipedia). The raw moments are calculated from the central moments.

$$\mu_X(k) = 2^{k/2}\Gamma(1+k/2)L_{k/2}^{((\nu-2)/2)}\left(-\tfrac{1}{2}\lambda^2\right)$$

$$L_n^{(\alpha)}(x) = \frac{\Gamma(\alpha+n+1)}{\Gamma(\alpha+1)\Gamma(n+1)}{}_1F_1(-n;\alpha+1;x)$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_chi_nc(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_chi_nc.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an noncentral chi distribution. The cumulants are calculated from the moments.

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_chi_nc(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.9.6 Rice (Nakagami-n) distribution

class ctx.**dist_rice**(*n1*, *n2*, *lambda*, ***kwargs*)

These functions return PDF, CDF, and ICDF of the Rice distribution with location a, scale $b > 0$, and the support interval $(-\infty, +\infty)$.

See also: Wikipedia [1229], Witkovský [1495].

dist_rice.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Rice distribution:

$$\mathrm{pdf}_X(x) = \frac{x}{\sigma^2} \exp\left(\frac{-(x^2+\nu^2)}{2\sigma^2}\right) I_0\left(\frac{x\nu}{\sigma^2}\right)$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", dist_rice(mu, sigma).pdf(x))
6.356352346256452561561561456135 6E-20
```

dist_rice.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Rice distribution:

$$\mathrm{cdf}_X(x) = 1 - Q_1\left(\frac{\nu}{\sigma}, \frac{x}{\sigma}\right)$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", dist_rice(mu, sigma).pdf(x))
6.356352346256452561561561456135 6E-20
```

dist_rice.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following an Rice distribution:

$$\mathrm{sf}_X(x) = 1 - \mathrm{cdf}_X(x).$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", dist_rice(mu, sigma).pdf(x))
sf: 6.356352346256452561561561456135 6E-20
```

dist_rice.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an Rice distribution:

$$\mathrm{qtf}_X(q) = ??$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", dist_rice(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_rice.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following an Rice distribution:

$$\text{isf}_X(q) = ??$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", dist_rice(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_rice.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an Rice distribution:

$$C_X(t) = ??$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_rice(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_rice.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following an Rice distribution:

$$M_X(t) = ??$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", dist_rice(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_rice.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an Rice distribution:

$$K_X(t) = ??$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", dist_rice(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_rice.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an Rice distribution (Wikipedia). The raw moments are calculated from the central moments.

$$\mu_X(r) = \sigma^k 2^{k/2}\,\Gamma(1+k/2)\,L_{k/2}(-\nu^2/2\sigma^2),$$

$$L_q(x) = L_q^{(0)}(x) = M(-q, 1, x) = {}_1F_1(-q; 1; x)$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_rice(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_rice.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an Rice distribution. The cumulants are calculated from the moments.

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dist_rice(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.9.7 Noncentral distribution of the sample correlation coefficient

class ctx.**dist_pearson_rho_nc**(*N*, *rho*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The noncentral distribution of Pearson's rho (the distribution of the sample correlation coefficient), with sample size $N \geq 3$, noncentrality parameter $\rho \in (-1, +1)$ is a continuous distribution with the support interval $(-1, +1)$. See also Wikipedia [1228], Hotelling [375], Guenther [355], Winterbottom [1456], Winterbottom [1457], Odeh [427], Ruben [494], Subrahmaniam and Subrahmaniam [509].

The correlation coefficient r in samples of size $N > 2$ from a non-singular bivariate normal population with correlation coefficent ρ can be represented in the form

$$\tilde{r} = (z + \tilde{\rho}\chi_{N-1})/\chi_{N-2}$$

where $\tilde{r} = r/\sqrt{1-r^2}$, $\tilde{\rho} = \rho/\sqrt{1-\rho^2}$, z is a standardized normal variate and z , χ_{N-1}, and χ_{N-2} are independent.

A random variable X follows the distribution of Pearson's correlation coefficient with sample size N and noncentrality parameter ρ, if $Y = X/(1-X)$ has the representation given above.

dist_pearson_rho_nc.**pdf**(*x*)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the noncentral distribution of Pearson's rho:

$$\text{pdf}_X(x) = f_R(r, N; \rho) = \frac{(N-2)\Gamma(N-1)}{\sqrt{2\pi}\Gamma\left(N-\frac{1}{2}\right)} A^{N-1} C^{N-4} (1-x)^{\frac{3}{2}-N} {}_2F_1\left(\tfrac{1}{2}, \tfrac{1}{2}; N-\tfrac{1}{2}; \tfrac{1}{2}+\tfrac{1}{2}\rho r\right),$$

where $A = \sqrt{1-\rho^2}$, $\quad C = \sqrt{1-r^2}$, and ${}_2F_1(\cdot)$ is the Gaussian hypergeometric function.

In the special case when $\rho = 0$, the exact density function $f(r)$ can be written as:

$$f(r) = \frac{(1-r^2)^{\frac{n-4}{2}}}{\mathbf{B}\left(\frac{1}{2}, \frac{n-2}{2}\right)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", pearson_rho_nc(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_pearson_rho_nc.**cdf**(*x*)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the noncentral distribution of Pearson's rho:

$$\text{cdf}_X(x) = F_{R^2}(x; p, N, \rho^2) = \int_{-1}^{x} f_{R^2}(x; p, N, \rho^2)\mathrm{d}t$$

Two additional algorithms by Hotelling(1953) are also used to cover a broader range of parameters.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", pearson_rho_nc(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_pearson_rho_nc.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following the noncentral distribution of Pearson's rho:

$$\mathrm{sf}_X(x) = 1 - \mathrm{cdf}_X(x) = \int_x^1 \mathrm{pdf}_X(x)\mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", pearson_rho_nc(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_pearson_rho_nc.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following the noncentral distribution of Pearson's rho:

There is no known closed form for the quantile function $\mathrm{cdf}_X^{-1}(q)$: It is computed with Newton iterations where the starting values are from a approximation by Winterbottom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", pearson_rho_nc(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_pearson_rho_nc.**isf**(q)

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the noncentral distribution of Pearson's rho:

$$\mathrm{isf}_X(q) = \mathrm{qtf}_X(1-q) = \mathrm{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", pearson_rho_nc(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_pearson_rho_nc.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following the noncentral distribution of Pearson's rho:

$$C_X(t) = \int_{-1}^{1} e^{itx}\mathrm{pdf}_X(x)\mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", pearson_rho_nc(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_pearson_rho_nc.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following the noncentral distribution of Pearson's rho:

$$M_X(t) = \int_{-1}^{1} e^{tx} \text{pdf}_X(x) \text{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", pearson_rho_nc(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_pearson_rho_nc.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function:

$$K_X(t) = \log(M_X(t))$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", pearson_rho_nc(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_pearson_rho_nc.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the noncentral distribution of Pearson's rho: the moments are calculated from their definition:

$$\mu'_X(r) = E(X^r) = \int_{-1}^{1} x^r \text{pdf}_X(x) \text{d}x$$

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of Pearson's rho:

Johnson *et al.* [388], 2nd vol, page 555, gives the following formulas:

$$\mu_{2k+1} = \frac{B((k+1)/2), (n-2)/2}{B(1/2, (n-2)/2)} (1-\rho^2)^{(n-1)/2} \times {}_3F_2\left(\frac{k+1}{2}, \frac{n-1}{2}, \frac{n-1}{2}, \frac{n+k-1}{2}, \frac{1}{2}; \rho^2\right)$$

$$\mu_{2k} = \frac{(n-2)B((k+2)/2), (n-2)/2}{B(1/2, (n-2)/2)} (1-\rho^2)^{(n-1)/2} \times {}_3F_2\left(\frac{k+2}{2}, \frac{n}{2}, \frac{n}{2}, \frac{n+k}{2}, \frac{3}{2}; \rho^2\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", pearson_rho_nc(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_pearson_rho_nc.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the noncentral distribution of Pearson's rho. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", pearson_rho_nc(mu, sigma).cumulants(k))
6.356352346256452561561561561456135 6E+00
```

Additional methods: Results based on Fisher's z-transformation

The generating functions and cumulants all exist, but are complicated and not useful for numerical work. Asymptotic expansions typically rely on the Fisher z-transform $Z(a) = \text{atanh}(a)$ and its inverse $Z^{-1}(a) = \tanh(a)$.

Let $m = N - 1$ and let $u_\alpha = \Phi^{-1}(\alpha)$ be the lower 100α percentage point of the standard normal distribution. The first 4 cumulants of $Z(X)$ are given by

$$\kappa_1 = \tfrac{1}{2}\log\left(\frac{1+\rho}{1-\rho}\right) + \frac{\rho}{2m} + \frac{5+\rho^2}{4m^2} + \frac{11+2\rho^2+3\rho^4}{8m^3} + O(m^{-4}),$$

$$\kappa_2 = \frac{1}{m} + \frac{4-\rho^2}{2m^2} + \frac{22-6\rho^2-3\rho^4}{6m^3} + O(m^{-4}), \quad \kappa_3 = \frac{\rho^3}{m^3} + O(m^{-4}), \quad \kappa_4 = \frac{2}{m^3} + O(m^{-4}).$$

4.9.8 Distribution of the logarithm of a noncentral Beta Type II variable

class ctx.**dist_logrv_beta_nc_type_II**(*a*, *b*, *lambda1*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The noncentral Beta Type II distribution is a continuous probability distribution with shape parameters a and b, noncentrality parameter λ_1 and the support interval $(0, 1)$. See also Wikipedia [1165], MathWorld [245], BoostMath [63], Wang and Gray [795], Witkovský [1475], Johansson [386], R (Statistical System) [516].

A random variable X follows a Type I noncentral beta distribution with shape parameters a and b and noncentrality parameter λ, if it is defined as $X = U_1/(U_1 + U_2)$ where U_1 and U_2 are independent with $U_1 \sim \chi^2(n_1, \lambda)$, and $U_2 \sim \chi^2(n_2)$ $n_1 = 2a$ and $n_2 = 2b$ are the degrees of freedom, and λ is the noncentrality parameter of the noncentral χ^2 distribution. The random variable $Y = 1 - X$ is said to follow a Type II noncentral beta distribution with shape parameters a and b and noncentrality parameter λ.

dist_logrv_beta_nc_type_II.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a Type I noncentral beta distribution:

$$\mathrm{pdf}_X(x) = f_{\mathrm{Beta}'}(x; a, b, \lambda) = e^{-\lambda/2} f_{\mathrm{Beta}}(x; a, b) \times {}_1F_1\left((a+b), b, \tfrac{nx\lambda}{2(m+nx)}\right)$$

and $f_{\mathrm{Beta}}(\cdot)$ and $F_{\mathrm{Beta}}(\cdot)$ denote the PDF and CDF, respectively, of the central Beta-distribution, and ${}_1F_1(\cdot)$ is the confluent hypergeometric function. There is no known explicit form for the quantile function $\mathrm{cdf}_X^{-1}(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", beta_nc_type_II(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_logrv_beta_nc_type_II.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Type I noncentral beta distribution:

$$\mathrm{cdf}_X(x) = F_{\mathrm{Beta}'}(x; a, b, \lambda) = \int_0^x f_{\mathrm{Beta}'}(x; a, b, \lambda)\mathrm{d}t = e^{-\lambda/2} \sum_{j=0}^{\infty} \frac{(\lambda/2)^j}{j!} F_{\mathrm{Beta}}(x; a+j, b)$$

and $f_{\mathrm{Beta}}(\cdot)$ and $F_{\mathrm{Beta}}(\cdot)$ denote the PDF and CDF, respectively, of the central Beta-distribution, and ${}_1F_1(\cdot)$ is the confluent hypergeometric function. There is no known explicit form for the quantile function $\mathrm{cdf}_X^{-1}(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", beta_nc_type_II(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_logrv_beta_nc_type_II.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a Type I noncentral beta distribution:

$$\mathrm{sf}_X(x) = 1 - \mathrm{cdf}_X(x) = \int_x^1 \mathrm{pdf}_X(x)\mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", beta_nc_type_II(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_logrv_beta_nc_type_II.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Type I noncentral beta distribution:

There is no known closed form for the quantile function $\text{cdf}_X^{-1}(q)$: It is computed with Newton iterations where the starting values are from a approximation by Winterbottom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", beta_nc_type_II(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_logrv_beta_nc_type_II.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Type I noncentral beta distribution:

$$\text{isf}_X(q) = \text{qtf}_X(1-q) = \text{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", beta_nc_type_II(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

It is more convenient to work with Y rather than X to obtain generating functions and moments: the characteristic function, $C_Y(t)$, moment generating function, $M_Y(t)$, cumulant generating function and its j^{th} derivative, $K_Y(t)$ and $K_Y^{(j)}(t)$, and the r^{th} raw moment, $\mu'_Y(r)$, of Y are given below:

dist_logrv_beta_nc_type_II.**c_y**(t)

Returns $C_Y(s)$, the characteristic function of a random variable Y, as defined above:

$$C_Y(t) = \frac{\Gamma(n/2 - it)\Gamma((n+m)/2)}{\Gamma(n/2)\Gamma((n+m)/2 - it)} \times {}_1F_1\left(-it; \frac{n+m}{2} - it; -\frac{1}{2}\lambda\right),$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_f_nc_type_II(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_logrv_beta_nc_type_II.**m_y**(t)

Returns $M_Y(s)$, the moment generating function of a random variable Y, as defined above:

$$M_Y(t) = \frac{\Gamma(n/2 + t)\Gamma((n+m)/2)}{\Gamma(n/2)\Gamma((n+m)/2 + t)} \times {}_1F_1\left(t, \tfrac{1}{2}(n+m) + t, -\tfrac{1}{2}\lambda\right),$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_f_nc_type_II(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_logrv_beta_nc_type_II.**k_y**(t, *k=0*)

Returns $K_Y(s)$, the cumulant generating function, and its j^{th} derivatives, $K_Y^{(j)}(s), j = 1 \ldots k$, of a random variable Y, as defined above:

$$K_Y(t) = \log\left[\frac{\Gamma(n/2+t)\Gamma((n+m)/2)}{\Gamma(n/2)\Gamma((n+m)/2+t)} \times {}_1F_1\left(t, \tfrac{1}{2}(n+m)+t, -\tfrac{1}{2}\lambda\right)\right],$$

$$K_Y^{(j)}(t) = \psi^{(j-1)}\left(\tfrac{1}{2}n + t - \tfrac{1}{2}(i-1)\right) - \psi^{(j-1)}\left(\tfrac{1}{2}(n+m) + t - \tfrac{1}{2}(i-1)\right) \tag{4.23}$$

$$+ \frac{\partial}{\partial t}\log\left[{}_1F_1\left(t, \tfrac{1}{2}(n+m)+t, -\tfrac{1}{2}\lambda\right)\right], \tag{4.24}$$

where $\psi^{(j-1)}(\cdot)$ denotes the polygamma function and ${}_1F_1(\cdot)$ is the confluent hypergeometric function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", fisher_f_nc_type_II(mu, sigma).k_x(t, k))
6.3563523462564525615615615614561356E+00
```

dist_logrv_beta_nc_type_II.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of the square of the multiple correlation coefficient: the moments are calculated from their definition:

$$\mu'_X(r) = E(X^r) = \int_0^1 x^r \text{pdf}_X(x)\text{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_r_square_type_II(mu, sigma).moments(k))
6.3563523462564525615615615614561356E+00
```

dist_logrv_beta_nc_type_II.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of the square of the multiple correlation coefficient. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_r_square_type_II(mu, sigma).cumulants(k))
6.3563523462564525615615615614561356E+00
```

Approximations

ctx.**log1mbeta_nc_gp**(*t*, *n*, *m*, *lambda1*)

where ctx is dec, mpm, fpm, gmp or apm.

Calculates the pdf, cdf and sf from the characteristic function using the procedure of Gil-Pelaez (see *gil_pelaez_pdf()* and *gil_pelaez_cdf()*).

This uses $\log(1-X)$, X noncentral beta

ctx.**beta_nc_spa**(*x*, *n*, *results='c'*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

Calculates the Luggannini-Rice saddlepoint approximation of the pdf, cdf and sf.

This uses $2\log(1-X)$ of the non-central beta X

Returns $K_Y(s)$, the cumulant generating function, and its j^{th} derivatives, $K_Y^{(j)}(s), j = 1 \ldots k$, of a random variable Y, as defined above:

$$K_Y(t) = \log\left[\frac{\Gamma(n/2+t)\Gamma((n+m)/2)}{\Gamma(n/2)\Gamma((n+m)/2+t)} \times {}_1F_1\left(t, \tfrac{1}{2}(n+m)+t, -\tfrac{1}{2}\lambda\right)\right],$$

$$\begin{aligned} K_Y^{(j)}(t) &= \psi^{(j-1)}\left(\tfrac{1}{2}n + t - \tfrac{1}{2}(i-1)\right) - \psi^{(j-1)}\left(\tfrac{1}{2}(n+m) + t - \tfrac{1}{2}(i-1)\right) && (4.25)\\ &+ \frac{\partial}{\partial t}\log\left[{}_1F_1\left(t, \tfrac{1}{2}(n+m)+t, -\tfrac{1}{2}\lambda\right)\right], && (4.26)\end{aligned}$$

where $\psi^{(j-1)}(\cdot)$ denotes the polygamma function and ${}_1F_1(\cdot)$ is the confluent hypergeometric function.

ctx.**beta_nc_spa_inv**(*x*, *n*, *results='qtf'*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

This uses $2\log(1-X)$ of the non-central beta X

4.9.9 Noncentral distribution (Type I) of Fisher's R^2

class ctx.**dist_fisher_r2_type_I**(*p*, *N*, *rho2*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of Fisher's R^2 Type I (the distribution of the square of the sample multiple correlation coefficient), with $p \geq 1$ predictor variables, sample size $N \geq p+2$ and noncentrality parameter $\rho^2 \in (0,1)$ is a continuous probability distribution with the support interval $(0,1)$. See also Lee [407], Lee [408], Gurland [357], Gurland and Milton [359], Gurland and Asiribo [358], Muirhead [418], Benton and Krishnamoorthy [30], Fisher [336], Gatsonis and Sampson [343], Kelley [392].

A random variable X follows the distribution of Fisher's R^2 (the square of the multiple correlation coefficient) with p variables, sample size N and noncentrality parameter ρ^2, if $G = X/(1-X)$ has the representation

$$G = \frac{(\tilde{\rho}\chi_{N-1} + z)^2 + \chi^2_{p-1}}{\chi^2_{N-1-p}},$$

where $\tilde{\rho} = \sqrt{\rho^2/(1-\rho^2)}$, z is a standard normal variate, χ_f and χ^2_f are chi and chi-square variates on f degrees of freedom, and the variates figuring in this relation are independently distributed.

dist_fisher_r2_type_I.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of the square of the multiple correlation coefficient:

$$\mathrm{pdf}_X(x) = f_{R^2}(x; p, N, \rho^2) = f_{\text{Beta}}\left(x; \tfrac{1}{2}(p-1), \tfrac{1}{2}(N-p)\right) \times (1-\rho^2)^{n/2} \times {}_2F_1(\tfrac{1}{2}N, \tfrac{1}{2}N, \tfrac{1}{2}p; \rho^2 x),$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", fisher_r_square_type_I(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_fisher_r2_type_I.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of the square of the multiple correlation coefficient:

$$\begin{aligned} \mathrm{cdf}_X(x) &= F_{R^2}(x; p, N, \rho^2) = \int_0^x f_{R^2}(x; p, N, \rho^2)\mathrm{d}t \\ &= \sum_{i=0}^{\infty} f_{\text{NegBin}}\left((N-1)/2, i; 1-\rho^2\right) \times F_{\text{Beta}}\left(x; \tfrac{1}{2}(p-1)+i, \tfrac{1}{2}(N-p)\right), \end{aligned} \tag{4.27}$$

and $f_{\text{Beta}}(\cdot)$ and $F_{\text{Beta}}(\cdot)$ denote the PDF and CDF, respectively, of the central Beta-distribution, $f_{\text{NegBin}}(\cdot)$ denotes the PMF of the negative binomial distribution and and ${}_2F_1(\cdot)$ is the Gaussian hypergeometric function. There is no known explicit form for the quantile function $\mathrm{cdf}^{-1}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", fisher_r_square_type_I(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_fisher_r2_type_I.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following the distribution of the square of the multiple correlation coefficient:

$$\mathrm{sf}_X(x) = 1 - \mathrm{cdf}_X(x) = \int_x^1 \mathrm{pdf}_X(x)\mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_r_square_type_I(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_fisher_r2_type_I.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following the distribution of the square of the multiple correlation coefficient:

There is no known explicit form for the quantile function $\mathrm{cdf}_X^{-1}(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_r_square_type_I(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_fisher_r2_type_I.**isf**(q)

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of the square of the multiple correlation coefficient:

$$\mathrm{isf}_X(q) = \mathrm{qtf}_X(1-q) = \mathrm{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_r_square_type_I(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_fisher_r2_type_I.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of the square of the multiple correlation coefficient:

$$C_X(t) = \int_0^1 e^{itx}\mathrm{pdf}_X(x)\mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_r_square_type_I(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_fisher_r2_type_I.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following the distribution of the square of the multiple correlation coefficient:

$$M_X(t) = \int_0^1 e^{tx} \text{pdf}_X(x) \text{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_r_square_type_I(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_fisher_r2_type_I.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function:

$$K_X(t) = \log(M_X(t))$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", fisher_r_square_type_I(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_fisher_r2_type_I.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of the square of the multiple correlation coefficient: the moments are calculated from their definition:

$$\mu'_X(r) = E(X^r) = \int_0^1 x^r \text{pdf}_X(x) \text{d}x$$

The moments of $Y = 1 - X$ are given by:

$$\mu'_Y(r) = \frac{\Gamma(n/2 + r)\Gamma((n + m)/2)}{\Gamma(n/2)\Gamma((n + m)/2 + r)} \times {}_2F_1\left(r; \frac{n + m}{2} + r; -\tfrac{1}{2}\rho^2\right),$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_r_square_type_I(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_fisher_r2_type_I.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of the square of the multiple correlation coefficient. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_r_square_type_I(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

Additional information: Moments of Fisher's `R^2`

[Muirhead1982` p. 178, gives the following formula (see also Johnson *et al.* [388] p. 621)

$$\mathrm{E}[(1-R^2)^h] = \frac{\left[\frac{1}{2}(n-m+1)\right]_h}{\left(\frac{1}{2}n\right)_h}(1-\bar{R}^2)^h \times {}_2F_1(h,h,\tfrac{1}{2}n+h;\bar{R}^2).$$

where $(a)_k$ is the Pochammer symbol and ${}_2F_1(\cdot)$ is the Gaussian hypergeometric function.

The lower order moments are given by

$$\mu_1' = 1 - \frac{(n-m+1)}{n}(1-\bar{R}^2)^h \times {}_2F_1(1,1,\tfrac{1}{2}n+1;\bar{R}^2).$$

$$\mathrm{E}[(1-R^2)^2] = \frac{\left[\frac{1}{2}(n-m+1)\right]_2}{\left(\frac{1}{2}n\right)_2}(1-\bar{R}^2)^2 \times {}_2F_1(2,2,\tfrac{1}{2}n+2;\bar{R}^2).$$

Additional information: Random number generation for Fisher's `R^2`

A notable result concerning the distribution of R^2 is that $\tilde{R}^2 = R^2/(1-R^2)$ has the representation

$$\tilde{R}^2 = \frac{(\tilde{\rho}\chi_n + z)^2 + \chi^2_{p-1}}{\chi^2_{n-p}}$$

where $\tilde{\rho}^2 = \rho^2/(1-\rho^2)$, n is the sample size less one, z is a standard normal variate, χ_f and χ^2_f are chi and chi-square variates on f degrees of freedem; the variates figuring in this relation are independently distributed and $\tilde{\rho}$ is taken to be positive (see Lee [407]).

Additional information: Recurrence relations for the pdf

For the particular cases of $p = 3$ and $p = 5$, we have for the pdf (see Lee [407]):

$$f_{R^2}(n,3;\rho^2) = \frac{(n-3)\sqrt{1-\rho^2}\,[f_R(n-1,R;\rho) - f_R(n-1,-R;\rho)]}{2(n-2)\rho\sqrt{1-R^2}}$$

$$\begin{aligned} f_{R^2}(n,5;\rho^2) &= \frac{(n-5)(1-\rho^2)R\,[f_R(n-2,R;\rho) + f_R(n-2,-R;\rho)]}{2(n-2)\rho^2(1-R^2)} \\ &- \frac{2(1-\rho^2)(1-R^2)f_{R^2}(n-2,3;\rho^2)}{2(n-2)\rho^2(1-R^2)} \end{aligned} \tag{4.28}$$

where $f_R(\cdot)$ denotes the pdf of the distribution of the sample correlation coeffcient. Starting with these formulas, the pdf can be calculated for all odd p, using the following recurrence relation, which is valid for all integer values of $p \geq 6$:

$$\begin{aligned} (n-2)\rho^2(1-R^2)f_{R^2}(n,p;\rho^2) &= (n-p)R^2(1-\rho^2)f_{R^2}(n-2,p-4;\rho^2) \\ &- (p-4)(1-\rho^2)(1-R^2)f_{R^2}(n-2,p-2;\rho^2) \end{aligned} \tag{4.29}$$

Additional information: Recurrence relations for the cdf

For the particular cases of $p = 3$ and $p = 5$, we have for the CDF Lee [407]:

$$F_{R^2}(n,3;\rho^2) = F_{R^2}(n,1;\rho^2) - \frac{\sqrt{(1-\rho^2)(1-R^2)}\,[f_R(n-1,R;\rho) - f_R(n-1,-R;\rho)]}{(n-2)\rho}$$

$$\begin{aligned} F_{R^2}(n,5;\rho^2) &= F_{R^2}(n,3;\rho^2) - \frac{(1-\rho^2)R\,[f_R(n-2,R;\rho) - f_R(n-2,-R;\rho)]}{(n-2)\rho} \\ &- \frac{(1-\rho^2)\left[F_{R^2}(n-2,3;\rho^2) - F_{R^2}(n-2,1;\rho^2)\right]}{(n-2)\rho} \end{aligned} \tag{4.30}$$

where $F_R(\cdot)$ denotes the CDF of the distribution of the sample correlation coeffcient. Starting with these formulas, the CDF can be calculated for all odd p, using the following recurrence relations for the cdf, which is valid for all integer values of $p \geq 6$:

$$\begin{aligned}(n-2)\rho^2(1-R^2)F_{R^2}(n,p;\rho^2) &= (n-p)\rho^2 F_{R^2}(n,p-2;\rho^2) \\ &- (p-4)(1-\rho^2)\left[F_{R^2}(n-2,p-2;\rho^2) - F_{R^2}(n-2,p-4;\rho^2)\right] \\ &- 2R^2(1-\rho^2)f_{R^2}(n-2,p-4;\rho^2)\end{aligned} \tag{4.31}$$

4.9.10 Distribution of the logarithm of a noncentral Fisher $1 - R^2$ variable

class ctx.**dist_logrv_fisher_1mr2**(*p*, *N*, *rho2*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of Fisher's R^2 Type II with $p \geq 1$ predictor variables, sample size $N \geq p + 2$ and noncentrality parameter $\rho^2 \in (0, 1)$ is a continuous probability distribution with the support interval $(0, 1)$. See also Lee [407], Lee [408], Gurland [357], Gurland and Milton [359], Gurland and Asiribo [358], Muirhead [418], Benton and Krishnamoorthy [30], Fisher [336], Gatsonis and Sampson [343].

A random variable X follows the distribution of Fisher's R^2 (the square of the multiple correlation coefficient) with p variables, sample size N and noncentrality parameter ρ^2, if $G = X/(1 - X)$ has the representation

$$G = \frac{(\tilde{\rho}\chi_{N-1} + z)^2 + \chi^2_{p-1}}{\chi^2_{N-1-p}},$$

where $\tilde{\rho} = \sqrt{\rho^2/(1 - \rho^2)}$, z is a standard normal variate, χ_f and χ^2_f are chi and chi-square variates on f degrees of freedom, and the variates figuring in this relation are independently distributed.

dist_logrv_fisher_1mr2.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of the square of the multiple correlation coefficient:

$$\mathrm{pdf}_X(x) = f_{R^2}(x; p, N, \rho^2) = f_{\text{Beta}}\left(x; \tfrac{1}{2}(p-1), \tfrac{1}{2}(N-p)\right) \times (1-\rho^2)^{n/2} \times {}_2F_1(\tfrac{1}{2}N, \tfrac{1}{2}N, \tfrac{1}{2}p; \rho^2 x),$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", fisher_r_square_type_II(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_logrv_fisher_1mr2.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of the square of the multiple correlation coefficient:

$$\begin{aligned} \mathrm{cdf}_X(x) &= F_{R^2}(x; p, N, \rho^2) = \int_0^x f_{R^2}(x; p, N, \rho^2)\mathrm{d}t \\ &= \sum_{i=0}^{\infty} f_{\text{NegBin}}\left((N-1)/2, i; 1-\rho^2\right) \times F_{\text{Beta}}\left(x; \tfrac{1}{2}(p-1)+i, \tfrac{1}{2}(N-p)\right), \end{aligned} \tag{4.32}$$

and $f_{\text{Beta}}(\cdot)$ and $F_{\text{Beta}}(\cdot)$ denote the PDF and CDF, respectively, of the central Beta-distribution, $f_{\text{NegBin}}(\cdot)$ denotes the PMF of the negative binomial distribution and and ${}_2F_1(\cdot)$ is the Gaussian hypergeometric function. There is no known explicit form for the quantile function $\mathrm{cdf}^{-1}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", fisher_r_square_type_II(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_logrv_fisher_1mr2.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following the distribution of the square of the multiple correlation coefficient:

$$\mathrm{sf}_X(x) = 1 - \mathrm{cdf}_X(x) = \int_x^1 \mathrm{pdf}_X(x)\mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_r_square_type_II(mu, sigma).pdf(x))
sf: 6.356352346256452561561561561456135 6E-20
```

dist_logrv_fisher_1mr2.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following the distribution of the square of the multiple correlation coefficient:

There is no known explicit form for the quantile function $\mathrm{cdf}_X^{-1}(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_r_square_type_II(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561456135 6E+00
```

dist_logrv_fisher_1mr2.**isf**(q)

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of the square of the multiple correlation coefficient:

$$\mathrm{isf}_X(q) = \mathrm{qtf}_X(1-q) = \mathrm{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_r_square_type_II(mu, sigma).isf(q))
6.356352346256452561561561561456135 6E+00
```

It is more convenient to work with $Y = 1 - X$ rather than X to obtain generating functions and moments: the characteristic function, $C_Y(t)$, moment generating function, $M_Y(t)$, cumulant generating function and its j^{th} derivative, $K_Y(t)$ and $K_Y^{(j)}(t)$, and the r^{th} raw moment, $\mu'_Y(r)$, of Y are given below:

dist_logrv_fisher_1mr2.**c_y**(t)

Returns $C_Y(s)$, the characteristic function of a random variable Y (as defined above):

$$C_Y(t) = \frac{\Gamma(n/2 - it)\Gamma((n+m)/2)}{\Gamma(n/2)\Gamma((n+m)/2 - it)} \times {}_2F_1\left(-it; \frac{n+m}{2} - it; -\frac{1}{2}\rho^2\right),$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_f_nc(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_logrv_fisher_1mr2.**m_y**(t)

Returns $M_Y(s)$, the moment generating function of a random variable Y (as defined above):

$$M_Y(t) = \frac{\Gamma(n/2+t)\Gamma((n+m)/2)}{\Gamma(n/2)\Gamma((n+m)/2+t)} \times {}_2F_1\left(t, \tfrac{1}{2}(n+m)+t, -\tfrac{1}{2}\rho^2\right),$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", fisher_f_nc(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_logrv_fisher_1mr2.**k_y**(t, *k=0*)

Returns $K_Y(s)$, the cumulant generating function, and its j^{th} derivatives, $K_Y^{(j)}(s), j = 1 \ldots k$, of a random variable Y (as defined above):

$$K_Y(t) = \log\left[\frac{\Gamma(n/2+t)\Gamma((n+m)/2)}{\Gamma(n/2)\Gamma((n+m)/2+t)} \times {}_2F_1\left(t, \tfrac{1}{2}(n+m)+t, -\tfrac{1}{2}\rho^2\right)\right],$$

$$K_Y^{(j)}(t) = \psi^{(j-1)}\left(\tfrac{1}{2}n + t - \tfrac{1}{2}(i-1)\right) - \psi^{(j-1)}\left(\tfrac{1}{2}(n+m) + t - \tfrac{1}{2}(i-1)\right) \tag{4.33}$$

$$+ \frac{\partial}{\partial t}\log\left[{}_2F_1\left(t, \tfrac{1}{2}(n+m)+t, -\tfrac{1}{2}\rho^2\right)\right], \tag{4.34}$$

where $\psi^{(j-1)}(\cdot)$ denotes the polygamma function and ${}_2F_1(\cdot)$ is the Gaussian hypergeometric function. The solution $\hat{s}(y)$ of the saddlepoint equation $K_Y^{(1)}(\hat{s}(y)) = y$ needs to be determined numerically.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", fisher_f_nc(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_logrv_fisher_1mr2.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of the square of the multiple correlation coefficient: the moments are calculated from their definition:

$$\mu'_X(r) = E(X^r) = \int_0^1 x^r \text{pdf}_X(x)\text{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_r_square_type_II(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_logrv_fisher_1mr2.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of the square of the multiple correlation coefficient. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", fisher_r_square_type_II(mu, sigma).cumulants(k))
6.356352346256452561561561561456l356E+00
```

Approximations

`ctx.`**`fisher_log1mr2_gp`**(*t*, *p*, *N*, *rho2*)

where `ctx` is `dec`, `mpm`, `fpm`, `gmp` or `apm`.

Calculates the pdf, cdf and sf from the characteristic function using the procedure of Gil-Pelaez (see *gil_pelaez_pdf()* and *gil_pelaez_cdf()*).

This uses $Y = \log(1 - R^2)$

`ctx.`**`fisher_r2_spa`**(*x*, *n*, *results='c'*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the Luggannini-Rice saddlepoint approximation of the pdf, cdf and sf.

This uses $Y = \log(1 - R^2)$

`ctx.`**`fisher_r2_spa_inv`**(*x*, *n*, *results='qtf'*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

This uses $Y = \log(1 - R^2)$

4.9.11 Doubly non-central Student t distribution

class ctx.**dist_student_t_2nc**(*n*, *delta*, *theta*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The doubly non-central Student t distribution is a continuous probability distribution with $n > 0$ degrees of freedom, noncentrality parameters δ and θ, and support interval $(-\infty, +\infty)$. See also Broda and Paolella [160], Kocherlakota and Kocherlakota [394], Paolella [456], Paolella [457], Gessner [348],

dist_student_t_2nc.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a doubly non-central Student t distribution:

$$\mathrm{pdf}_X(x) = f_{t''}(t; n; \mu, \theta) = \sum_{i=0}^{\infty} \omega_{i,\theta} s_{i,n} f_{t'}(s_{i,n} x; n + 2i, \mu),$$

where $f_{t'}(\cdot)$ denotes the PDF of the singly noncentral t-distribution, and

$$\omega_{i,\theta} = \frac{\exp(-\theta/2)(\theta/2)^i}{i!} \quad \text{and} \quad s_{i,n} = \sqrt{\frac{n+2i}{n}}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", student_t_2nc(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_student_t_2nc.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a doubly non-central Student t distribution:

$$\mathrm{cdf}_X(x) = F_{t''}(x; n; \mu, \theta) = \int_0^x f_{t''}(x; n; \mu, \theta)\mathrm{d}t = \sum_{i=0}^{\infty} \omega_{i,\theta} s_{i,n} F_{t'}(s_{i,n} x; n + 2i, \mu),$$

where $F_{t'}(\cdot)$ denotes the CDF of the singly noncentral t-distribution, and

$$\omega_{i,\theta} = \frac{\exp(-\theta/2)(\theta/2)^i}{i!} \quad \text{and} \quad s_{i,n} = \sqrt{\frac{n+2i}{n}}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", student_t_2nc(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_student_t_2nc.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a doubly non-central Student t distribution:

$$\mathrm{sf}_X(x) = 1 - \mathrm{cdf}_X(x) = \int_x^{\infty} \mathrm{pdf}_X(x)\mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", student_t_2nc(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_student_t_2nc.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a doubly non-central Student t distribution:

There is no known explicit form for the quantile function $\text{cdf}_X^{-1}(x)$: It is computed using Newton iterations with starting values from a singly noncentral t approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", student_t_2nc(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_student_t_2nc.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a doubly non-central Student t distribution:

$$\text{isf}_X(q) = \text{qtf}_X(1-q) = \text{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", student_t_2nc(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_student_t_2nc.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a doubly non-central Student t distribution:

$$C_X(t) = \int_{-\infty}^{\infty} e^{itx} \text{pdf}_X(x) \mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", student_t_2nc(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_student_t_2nc.**m_x**(t)

Returns `NaN`, since the moment generating function does not exist.

dist_student_t_2nc.**k_x**(t, *k=0*)

Returns `NaN`, since the cumulant generating function does not exist.

dist_student_t_2nc.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a doubly non-central Student t distribution. The rth moment only exists for $n > r$ and is given by

$$\mu'_X(r) = \left(\tfrac{1}{2}n\right)^{r/2} \frac{\Gamma\left(\frac{1}{2}(n-r)\right)}{\Gamma\left(\frac{1}{2}n\right)} \times {}_1F_1(\tfrac{1}{2}r, \tfrac{1}{2}n, -\tfrac{1}{2}\theta) \times \sum_{i=0}^{\lfloor r/2 \rfloor} \binom{r}{2i} \frac{(2i)!}{2^i i!} \delta^{r-2i},$$

where ${}_1F_1(\cdot)$ denotes Kummer's confluent hypergeometric function.

where ctx is ipm, dec, mpm, or gmp.

Calculates the Cornish-Fisher approximation to the qtf and isf.

4.9.12 Doubly non-central Fisher F distribution

class ctx.**dist_fisher_f_2nc**(*m*, *n*, *lambda1*, *lambda2*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The doubly non-central Fisher F distribution is a continuous probability distribution with $m > 0$ and $n > 0$ degrees of freedom, noncentrality parameters $\lambda_1 \geq 0$ and $\lambda_2 \geq 0$, and the support interval $(0, +\infty)$. See also Butler and Paolella [166], Chou [179], Chattamvelli and Jones [175].

dist_fisher_f_2nc.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a doubly non-central Fisher F distribution:

$$\text{pdf}_X(x) = f_{F''}(x; n_1, n_2; \lambda_1, \lambda_2) = \sum_{i=0}^{\infty} \omega_{i,\lambda_2} s_{i,n} f_{F'}(s_{i,n}x; n + 2i, \lambda_1),$$

where $f_{F'}(\cdot)$ denotes the PDF of the singly noncentral F-distribution, and

$$\omega_{i,\lambda_2} = \frac{\exp(-\lambda_2/2)(\lambda_2/2)^i}{i!} \quad \text{and} \quad s_{i,n} = \sqrt{\frac{n+2i}{n}}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30

6.3563523462564525615615615614561356E+00
```

dist_fisher_f_2nc.**m_x**(t)

Returns `NaN`, since the moment generating function does not exist.

dist_fisher_f_2nc.**k_x**(t, *k=0*)

Returns `NaN`, since the cumulant generating function does not exist.

dist_fisher_f_2nc.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a doubly non-central Fisher F distribution. The rth moment only exists for $n_2 > 2r$, and is given by

$$\mu'_X(r) = \left(\frac{n_2}{n_1}\right)^r \Gamma(\tfrac{1}{2}n_1 + r)\Gamma(\tfrac{1}{2}n_2 - r) \times {}_1\widetilde{F}_1(-r; \tfrac{1}{2}n_1; -\tfrac{1}{2}\lambda_1) \times {}_1\widetilde{F}_1(r; \tfrac{1}{2}n_2; -\tfrac{1}{2}\lambda_2),$$

where ${}_1\widetilde{F}_1(a, b; z)$ denotes Kummer's regularized confluent hypergeometric function.

```

Recurrences: Doubly non-central Fisher F, recurrence pdf

ctx.**fisher_f_nc2_pdf_recurrence**(*x*, *lambda*, *start_n1*, *start_n2*, *target_n1*, *target_n2*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Applies a recurrence relation to calculate the cdf for different degrees of freedom for a given value of x. This is mostly useful when using asymptotic methods.

Let the density $g_{m,n}$ be that of m/n times an $F_{m,n}$ random variable. Let $G_{m,n}(y)$ be its distribution function, and let $g^{\lambda_1,\lambda_2}_{m,n}$ and $G^{\lambda_1,\lambda_2}_{m,n}(y)$ be the density and distribution function of its doubly noncentral version (the distribution of $\chi^2_m(\lambda_1)/\chi^2_n(\lambda_2)$). Then the following recurrence relations hold (see Chattamvelli and Jones [175])

$$n\left[G^{\lambda}_{m,n}(y) - G^{\lambda}_{m,n}(y)\right] = -2g^{\lambda}_{m,n}(y)$$

$$\lambda_1(1+y)g^{\lambda_1,\lambda_2}_{m+4,n}(y) = [\lambda_1 y - m(1+y)]g^{\lambda_1,\lambda_2}_{m+2,n}(y) + y(m+n)g^{\lambda_1,\lambda_2}_{m,n}(y) + \lambda_2 g^{\lambda_1,\lambda_2}_{m,n+2}(y).$$

$$\lambda_2(1+y)g^{\lambda_1,\lambda_2}_{m,n+4}(y) = [\lambda_2 y - n(1+y)]g^{\lambda_1,\lambda_2}_{m+2,n}(y) + (m+n)g^{\lambda_1,\lambda_2}_{m,n}(y) + \lambda_1 g^{\lambda_1,\lambda_2}_{m+2,n}(y).$$

$$\lambda_1 g^{\lambda_1,\lambda_2}_{m+4,n-2}(y) = -mg^{\lambda_1,\lambda_2}_{m+2,n}(y) + nyg^{\lambda_1,\lambda_2}_{m,n+2}(y) + \lambda_2 g^{\lambda_1,\lambda_2}_{m+2,n}(y).$$

Recurrences: Doubly non-central Fisher F, recurrence cdf

`ctx.fisher_f_nc2_cdf_recurrence(x, lambda, start_n1, start_n2, target_n1, target_n2)`

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Applies a recurrence relation to calculate the cdf for different degrees of freedom for a given value of *x*. This is mostly useful when using asymptotic methods.

$$\begin{aligned}\lambda_1(1+y)G^{\lambda_1,\lambda_2}_{m+6,n}(y) &= [\lambda_1 y-(m+2-\lambda_1)(1+y)]G^{\lambda_1,\lambda_2}_{m+4,n}(y)\\ &+ [(m+2)(1+y)+y(m+n-\lambda_1)]G^{\lambda_1,\lambda_2}_{m+2,n}(y)\\ &- y(m+n)G^{\lambda_1,\lambda_2}_{m,n}(y)+\lambda_2 y:cite:t:`G^{\lambda_1,\lambda_2}_{m+2,n+2}(y)-G^{\lambda_1,\lambda_2}_{m,n+2}(y)]\end{aligned} \tag{4.35}$$

$$\begin{aligned}[n(1+y)-\lambda_2]:cite:t:`G^{\lambda_1,\lambda_2}_{m,n+2}(y)-G^{\lambda_1,\lambda_2}_{m+2,n+2}(y) &= (m+n):cite:t:`G^{\lambda_1,\lambda_2}_{m+2,n}(y)-G^{\lambda_1,\lambda_2}_{m,n}(y)]\\ &+ \lambda_2(1+y)[G^{\lambda_1,\lambda_2}_{m+2,n}(y)-G^{\lambda_1,\lambda_2}_{m+2,n}(y)]\\ &- \lambda_1:cite:t:`G^{\lambda_1,\lambda_2}_{m+2,n}(y)-G^{\lambda_1,\lambda_2}_{m+4,n}(y)]\end{aligned} \tag{4.36}$$

$$\begin{aligned}(m+2):cite:t:`G^{\lambda_1,\lambda_2}_{m+2,n}(y) &= (\lambda_1-m-2)G^{\lambda_1,\lambda_2}_{m+4,n}(y)-\lambda_1 G^{\lambda_1,\lambda_2}_{m+6,n}(y)\\ &+ y[nG^{\lambda_1,\lambda_2}_{m,n}(y)-nG^{\lambda_1,\lambda_2}_{m+2,n}(y)\\ &- \lambda_2 G^{\lambda_1,\lambda_2}_{m,n}(y)-\lambda_2 G^{\lambda_1,\lambda_2}_{m+2,n}(y)]\end{aligned} \tag{4.37}$$

Approximations

`ctx.fisher_f_nc2_ecf(x, m, n, lambda1, lambda2, results='cdf')`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Edgeworth approximation to the pdf, cdf and sf. See also: MathWorld [811], Paolella [457], page 358-360.

`ctx.fisher_f_nc2_ecf_inv(q, m, n, lambda1, lambda2, results='qtf')`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Cornish-Fisher approximation to the qtf and isf.

`ctx.fisher_f_nc2_spa(x, m, n, lambda1, lambda2, results='cdf')`

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the Luggannini-Rice saddlepoint approximation of the pdf, cdf and sf.

A random variable X follows a doubly noncentral F-distribution with n_1 and n_2 degrees of freedom and noncentrality parameters λ_1 and λ_2, if it is defined as $X = (U_1/n_1)/(U_2/n_2)$, where U_1 and U_2 are independent with $U_i \sim \chi^2(n_i, \lambda_i)$, the n_i are the degrees of freedom, and the λ_i are the noncentrality parameters of the noncentral χ^2 distributions.

The moment generating function and the cumulant generating function of X do not exist. However, the CDF of X can also be computed by writing

$$\text{cdf}_X(x) = \Pr(X \le x) = \Pr\left(\frac{n_2}{n_1}U_1 - xU_2 \le 0\right) = \Pr\left(Y_x \le 0\right),$$

where Y_x is the so-defined linear combination of U_1 and U_2, and then using the inversion methods for weighted sums. In the following equations, we use these definitions:

$l_1 = n_2/n_1$, $l_2 = -x$, $v_1 = 1/(1-2sl_1)$, $v_2 = 1/(1-2sl_2)$, $g_1 = l_1 v_1$, $g_2 = l_2 v_2$, $c_j = 1$ for $j = 1$ and $c_j = 2(j-1)c_{j-1}$ for $j > 1$.

$K_{Y_x}(s)$, the cumulant generating function, and its j^{th} derivatives, $K^{(j)}_{Y_x}(s), j = 1 \ldots k$, of a random variable Y_x, are defined as:

$$K_{Y_x}(s) = \tfrac{1}{2}n_1\log(v_1) + \tfrac{1}{2}n_2\log(v_2) + s(\lambda_1 g_1 + \lambda_2 g_2)$$

$$K_{Y_x}^{(j)}(s) = c_j \left(g_1^j \left(n_1 + j\lambda_1 v_1 \right) + g_2^j \left(n_2 + j\lambda_2 v_2 \right) \right).$$

saddlepoint central

Returns the solution $\hat{s}$ of the saddlepoint equation $K_{Y_x}^{(1)}(\hat{s}) = 0$, which can be obtained in closed form

$$\hat{s_0} = \frac{n_1(f-1)}{2f(n_1+n_2}$$

saddlepoint noncentral

Returns the solution $\hat{s}$ of the saddlepoint equation $K_{Y_x}^{(1)}(\hat{s}) = 0$, which can be obtained in closed form

$$\hat{s_1} = \left(xn_1(n_1 + 2n_2 + \lambda) - n_1 n_2 - \sqrt{n_1 a_2} \right) / a_1, \quad \text{where } a_1 = 4n_2 x(n1 + n2),$$

$$a_2 = x^2 n_1^3 + 2x^2 n_1^2 \lambda + 2n_1^2 x n_2 + 4x^2 n_1 n_2 \lambda + n_1 \lambda^2 x^2 + 2n_1 \lambda x n_2 + n_2^2 n_1 + 4x n_2^2 \lambda.$$

saddlepoint doubly noncentral

The solution $\hat{s}$ of the saddlepoint equation $K_{Y_x}^{(1)}(\hat{s}) = 0$, which can be obtained in closed form

$$\hat{s_2} = -2p \cos\left(\tfrac{1}{3} \arccos(-\tfrac{1}{2} q p^{-3}) + \tfrac{1}{3}\pi \right) - a_2, \quad \text{where}$$

$p^2 = |3a_2^2 - a_1|/3$, $q = a_2(2a_2^2 - a_1) + a_0$, $a = 8x^2 n_2^2 (n_1 + n_2)$, $a_0 = (x\lambda_2 n_1^2 - (1-x) n_1^2 n_2 - n_1 n_2 \lambda_1)/a$,

$a_1 = (2(n_2^2 n_1 + n_1^2 n_2 x^2) - 4x n_1 n_2 (n_1 + n_2 + \lambda_1 + \lambda_2))/a$,

$a_2 = (8x(1-x) n_1 n_2^2 + 4x(n_2^3 + \lambda_2 n_2^2 - n_1^2 n_2 x - n_1 n_2 \lambda_1 x))/(3a)$.

While the PDF of X cannot be obtained directly from the above, it can be obtained from the CDF a follows: Let the density $g_{m,n}$ be that of m/n times an $F_{m,n}$ random variable. Let $G_{m,n}(y)$ be its distribution function, and let $g_{m,n}^{\lambda_1,\lambda_2}$ and $G_{m,n}^{\lambda_1,\lambda_2}(y)$ be the density and distribution function of its doubly noncentral version (the distribution of $\chi_m^2(\lambda_1)/\chi_n^2(\lambda_2)$). Then the following recurrence relations hold citep{Chattamvelli_1995}

$$n \left[G_{m,n+2}^{\lambda}(y) - G_{m-2,n+2}^{\lambda}(y) \right] = -2 g_{m,n}^{\lambda}(y)$$

`ctx.`**`fisher_f_nc2_spa_inv`**(*q*, *m*, *n*, *lambda1*, *lambda2*, *results='cdf'*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

An n-dimensional random variable $\mathbf{X}$ with mean vector $\boldsymbol{\mu}$ and covariance matrix $\boldsymbol{\Sigma}$ is said to have a nonsingular multivariate normal distribution, in symbols $\boldsymbol{X} \sim \mathcal{N}_n(\boldsymbol{\mu}, \boldsymbol{\Sigma})$, if $\boldsymbol{\Sigma}$ is positive definite, and the density function of $\mathbf{X}$ is of the form (see Tong 1990):

$$f(\boldsymbol{x}; \boldsymbol{\mu}, \boldsymbol{\Sigma}) = \frac{1}{(2\pi)^{n/2}|\boldsymbol{\Sigma}|^{1/2}} e^{-Q_n(\boldsymbol{x};\boldsymbol{\mu},\boldsymbol{\Sigma})/2}, \quad \boldsymbol{x} \in \Re^n$$

where

$$Q_n(\boldsymbol{x}; \boldsymbol{\mu}, \boldsymbol{\Sigma}) = (\boldsymbol{x} - \boldsymbol{\mu})'\boldsymbol{\Sigma}^{-1}(\boldsymbol{x} - \boldsymbol{\mu}).$$

The notion of cumulative distribution function (cdf) in one dimension can be extended to the multidimensional case, based on rectangular regions. We define the cdf $F(\mathbf{x})$ of a random vector $\mathbf{X}$ as the probability that all components $\mathbf{X}$ are less than or equal to the corresponding values in the vector $\mathbf{x}$:

$$F(\mathbf{x}) = \mathbb{P}(\mathbf{X} \leq \mathbf{x}), \quad \text{where } \mathbf{X} \sim \mathcal{N}(\boldsymbol{\mu}, \boldsymbol{\Sigma}).$$

See also: Genz(2009), Bretz(2003).

Let $\boldsymbol{R} = (\rho_{ij})$ be an $n \times n$ symmetric matrix such that it is either positive definite or positive semidefinite and $\rho_{ii} = 1 (i = 1, \ldots, n)$. Let $\mathbf{Z} = (Z_1, \ldots, Z_n)'$ have an $\mathcal{N}_n(\mathbf{0}, \boldsymbol{R})$ distribution, and let the univariate variable S be such that S is independent of $\boldsymbol{Z}$, and νS^2 has a $\chi^2(\nu)$ distribution. Then a natural generalization of the Student's t variable is

$$\boldsymbol{t} = (t_1, \ldots, t_n)' = \left(\frac{Z_1}{S}, \ldots, \frac{Z_n}{S}\right)'.$$

If $\boldsymbol{R}$ is positive definite, then the density of $\boldsymbol{t}$ (with correlation matrix $\boldsymbol{R}$ and degrees of freedom ν) is given by citep{Tong_1990}:

$$h(\boldsymbol{t}; \boldsymbol{R}, \nu) = \frac{\Gamma((n+\nu)/2)}{(\nu\pi)^{n/2}\Gamma(\nu/2)|\boldsymbol{R}|^{1/2}} \left(1 + \frac{1}{\nu}\boldsymbol{t}'\boldsymbol{R}^{-1}\boldsymbol{t}\right)^{-(n+\nu)/2}, \quad \boldsymbol{t} \in \Re^n.$$

The notion of cumulative distribution function (cdf) in one dimension can be extended to the multidimensional case, based on rectangular regions. We define the cdf $F(\mathbf{x})$ of a random vector $\mathbf{X}$ as the probability that all components $\mathbf{X}$ are less than or equal to the corresponding values in the vector $\mathbf{x}$:

$$F(\mathbf{x}) = \mathbb{P}(\mathbf{X} \leq \mathbf{x}), \quad \text{where } \mathbf{X} \sim \mathcal{N}(\boldsymbol{\mu}, \boldsymbol{\Sigma}).$$

See also: Genz(2009), Bretz(2003).

4.10.2 Normal maximum distribution, $\rho_{ij,i\neq j} = \rho$

class ctx.**dist_nmax_rho**(*rho*, *k*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of the maximum of $k \geq 2$ correlated standard normal variates, with common correlation $0 \leq \rho \leq 1$ is a continuous distribution with support interval $(-\infty, +\infty)$. See also Dunnett [292], Bechhofer and Dunnett [26], Grubbs [354], Bechhofer and Dunnett [26], Stoline and Ury [508], and Hahn and Hendrickson [361].

dist_nmax_rho.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of the maximum of $k \geq 2$ correlated standard normal variables:

$$\mathrm{pdf}_X(x) = f_{\mathrm{nmax_corr}}(x, \rho, k) = \frac{k}{b} \int_{-\infty}^{\infty} (\Phi(z_1))^{k-1} \, \phi(z_1) \, \phi(y) \, \mathrm{d}y, \quad \text{where}$$

$$z_1 = \frac{x + a}{b}, \quad a = y\sqrt{|\rho|}, \quad b = \sqrt{1 - \rho}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", mp_dunnett_t(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_nmax_rho.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of the maximum of $k \geq 2$ correlated standard normal variables:

$$\mathrm{cdf}_X(x) = F_{\mathrm{nmax_corr}}(x, \rho, k) = \int_{-\infty}^{\infty} \left[\Phi\left(\frac{x + \sqrt{|\rho|}y}{\sqrt{1-\rho}} \right) \right]^n \phi(y) \mathrm{d}y$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", mp_dunnett_t(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_nmax_rho.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following the distribution of the maximum of $k \geq 2$ correlated standard normal variables:

$$\mathrm{sf}_X(x) = 1 - \int_{-\infty}^{\infty} \left[\Phi\left(\frac{x + \sqrt{|\rho|}y}{\sqrt{1-\rho}} \right) \right]^n \phi(y) \mathrm{d}y$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", mp_dunnett_t(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_nmax_rho.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following the distribution of the maximum of $k \geq 2$ correlated standard normal variables:

There is no known explicit form for the quantile function $\text{cdf}_X^{-1}(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", mp_dunnett_t(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_nmax_rho.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following the distribution of the maximum of $k \geq 2$ correlated standard normal variables:

$$\text{isf}_X(q) = \text{qtf}_X(1-q) = \text{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", mp_dunnett_t(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_nmax_rho.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of the maximum of $k \geq 2$ correlated standard normal variables:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_dunnett_t(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_nmax_rho.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following the distribution of the maximum of $k \geq 2$ correlated standard normal variables:

$$M_X(t) = \int_0^\infty e^{tx} \text{pdf}_X(x) \mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_studentized_range(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_nmax_rho.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following the distribution of the maximum of $k \geq 2$ correlated standard normal variables:

$$K_X(t) = \log\left(M_X(t)\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_studentized_range(mu, sigma).c_x(t))
6.356352346256452561561561456135 6E+00
```

dist_nmax_rho.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of the maximum of $k \geq 2$ correlated standard normal variables.

$$\mu'_X(r) = E(X^r) = \int_0^\infty x^r \mathrm{pdf}_X(x)\mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_dunnett_t(mu, sigma).moments(k))
6.356352346256452561561561456135 6E+00
```

dist_nmax_rho.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of the maximum of $k \geq 2$ correlated standard normal variables. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_dunnett_t(mu, sigma).cumulants(k))
6.356352346256452561561561456135 6E+00
```

4.10.3 Normal maximum modulus distribution, $\rho_{ij,i\neq j} = \rho$

class ctx.**dist_nmm_rho**(*rho*, *k*, ***kwargs*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variates, with common correlation $0 \leq \rho \leq 1$ is a continuous distribution with support interval $(-\infty, +\infty)$. See also Dunnett [292], Bechhofer and Dunnett [26], Grubbs [354], Bechhofer and Dunnett [26], Stoline and Ury [508], and Hahn and Hendrickson [361].

dist_nmm_rho.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables:

$$\text{pdf}_X(x) = \frac{k}{b} \int_{-\infty}^{\infty} \left(\Phi(z_1) - \Phi(z_2)\right)^{k-1} \left(\phi(z_1) + \phi(z_1)\right) \phi(y)\, \mathrm{d}y, \quad \text{where}$$

$$z_1 = \frac{x+a}{b}, z_2 = \frac{-x+a}{b}, \quad a = y\sqrt{|\rho|}, \quad b = \sqrt{1-\rho}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", mp_dunnett_t(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_nmm_rho.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables:

$$\text{cdf}_X(x) = \int_{-\infty}^{\infty} \left[\Phi\left(\frac{x+\sqrt{|\rho|}y}{\sqrt{1-\rho}}\right) - \Phi\left(\frac{-x+\sqrt{|\rho|}y}{\sqrt{1-\rho}}\right)\right]^k \phi(y)\mathrm{d}y$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", mp_dunnett_t(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_nmm_rho.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function function (sf) of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables:

$$\text{sf}_X(x) = 1 - \int_{-\infty}^{\infty} \left[\Phi\left(\frac{x+\sqrt{|\rho|}y}{\sqrt{1-\rho}}\right) - \Phi\left(\frac{-x+\sqrt{|\rho|}y}{\sqrt{1-\rho}}\right)\right]^k \phi(y)\mathrm{d}y$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", mp_dunnett_t(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_nmm_rho.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables:

There is no known explicit form for the quantile function $\text{cdf}_X^{-1}(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", mp_dunnett_t(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_nmm_rho.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables:

$$\text{isf}_X(q) = \text{qtf}_X(1-q) = \text{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", mp_dunnett_t(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_nmm_rho.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_dunnett_t(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_nmm_rho.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables:

$$M_X(t) = \int_0^\infty e^{tx} \text{pdf}_X(x) \mathrm{d}x$$

dist_nmm_rho.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables:

$$K_X(t) = \log\left(M_X(t)\right)$$

dist_nmm_rho.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables.

$$\mu'_X(r) = E(X^r) = \int_0^\infty x^r \mathrm{pdf}_X(x)\mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_dunnett_t(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_nmm_rho.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_dunnett_t(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.10.4 Normal maximum distribution, $\rho_{ij,i\neq j} = \lambda_i \lambda_j$

class ctx.**dist_nmax_rhoij**(*rho*, *k*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of the maximum of $k \geq 2$ correlated standard normal variates, with common correlation $0 \leq \rho \leq 1$ is a continuous distribution with support interval $(-\infty, +\infty)$. See also Dunnett [292], Bechhofer and Dunnett [26], Grubbs [354], Bechhofer and Dunnett [26], Stoline and Ury [508], and Hahn and Hendrickson [361].

dist_nmax_rhoij.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of the maximum of $k \geq 2$ correlated standard normal variables:

$$\text{pdf}_X(x) = f_{\text{nmaxrhoij}}(x, \rho, k) = \frac{k}{b} \int_{-\infty}^{\infty} (\Phi(z_1))^{k-1} \, \phi(z_1) \, \phi(y) \, \mathrm{d}y, \quad \text{where}$$

$$z_1 = \frac{x + a}{b}, \quad a = y\sqrt{|\rho|}, \quad b = \sqrt{1 - \rho}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;

6.35635234625645256156156145613 56E-20
```

dist_nmax_rhoij.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function function (sf) of a random variable X, following the distribution of the maximum of $k \geq 2$ correlated standard normal variables:

$$\text{sf}_X(x) = 1 - \int_{-\infty}^{\infty} \left[\Phi\left(\frac{x + \sqrt{|\rho|}y}{\sqrt{1-\rho}} \right) \right]^n \phi(y) \mathrm{d}y$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", mp_dunnett_t(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_nmax_rhoij.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following the distribution of the maximum of $k \geq 2$ correlated standard normal variables:

There is no known explicit form for the quantile function $\text{cdf}_X^{-1}(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", mp_dunnett_t(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_nmax_rhoij.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following the distribution of the maximum of $k \geq 2$ correlated standard normal variables:

$$\text{isf}_X(q) = \text{qtf}_X(1-q) = \text{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", mp_dunnett_t(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_nmax_rhoij.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of the maximum of $k \geq 2$ correlated standard normal variables:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30

```

dist_nmax_rhoij.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following the distribution of the maximum of $k \geq 2$ correlated standard normal variables:

$$K_X(t) = \log\left(M_X(t)\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_studentized_range(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_nmax_rhoij.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of the maximum of $k \geq 2$ correlated standard normal variables.

$$\mu'_X(r) = E(X^r) = \int_0^\infty x^r \mathrm{pdf}_X(x)\mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_dunnett_t(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_nmax_rhoij.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of the maximum of $k \geq 2$ correlated standard normal variables. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_dunnett_t(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.10.5 Normal maximum modulus distribution, $\rho_{ij,i\neq j} = \lambda_i \lambda_j$

class ctx.**dist_nmm_rhoij**(*rho*, *k*, ***kwargs*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variates, with common correlation $0 \leq \rho \leq 1$ is a continuous distribution with support interval $(-\infty, +\infty)$. See also Dunnett [292], Bechhofer and Dunnett [26], Grubbs [354], Bechhofer and Dunnett [26], Stoline and Ury [508], and Hahn and Hendrickson [361].

dist_nmm_rhoij.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables:

$$\text{pdf}_X(x) = \frac{k}{b} \int_{-\infty}^{\infty} \left(\Phi(z_1) - \Phi(z_2)\right)^{k-1} \left(\phi(z_1) + \phi(z_1)\right) \phi(y)\, \mathrm{d}y, \quad \text{where}$$

$$z_1 = \frac{x+a}{b}, z_2 = \frac{-x+a}{b}, \quad a = y\sqrt{|\rho|}, \quad b = \sqrt{1-\rho}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", mp_dunnett_t(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_nmm_rhoij.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables:

$$\text{cdf}_X(x) = \int_{-\infty}^{\infty} \left[\Phi\left(\frac{x+\sqrt{|\rho|}y}{\sqrt{1-\rho}}\right) - \Phi\left(\frac{-x+\sqrt{|\rho|}y}{\sqrt{1-\rho}}\right)\right]^k \phi(y)\mathrm{d}y$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", mp_dunnett_t(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_nmm_rhoij.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function function (sf) of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables:

$$\text{sf}_X(x) = 1 - \int_{-\infty}^{\infty} \left[\Phi\left(\frac{x+\sqrt{|\rho|}y}{\sqrt{1-\rho}}\right) - \Phi\left(\frac{-x+\sqrt{|\rho|}y}{\sqrt{1-\rho}}\right)\right]^k \phi(y)\mathrm{d}y$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", mp_dunnett_t(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_nmm_rhoij.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables:

There is no known explicit form for the quantile function $\text{cdf}_X^{-1}(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", mp_dunnett_t(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_nmm_rhoij.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables:

$$\text{isf}_X(q) = \text{qtf}_X(1-q) = \text{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", mp_dunnett_t(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_nmm_rhoij.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_dunnett_t(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_nmm_rhoij.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables:

$$M_X(t) = \int_0^\infty e^{tx} \text{pdf}_X(x) \mathrm{d}x$$

dist_nmm_rhoij.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables:

$$K_X(t) = \log\left(M_X(t)\right)$$

dist_nmm_rhoij.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables.

$$\mu'_X(r) = E(X^r) = \int_0^\infty x^r \text{pdf}_X(x) \text{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_dunnett_t(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_nmm_rhoij.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of the maximum of the absolute value of $k \geq 2$ correlated standard normal variables. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_dunnett_t(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.10.6 Normal range distribution

class ctx.**dist_normal_range**(k)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The normal range distribution is a continuous probability distribution with $k \geq 2$ groups, and the support interval $(0, +\infty)$. See also Wikipedia [1220], Harter [364], R (Statistical System) [536], and *dist_normal_range()*.

dist_normal_range.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a central normal range distribution:

$$\mathrm{pdf}_X(x) = k(k-1)\int_{-\infty}^{\infty} (\Phi(y) - \Phi(y-x))^{k-2}\,\phi(y)\phi(y-x)\mathrm{d}y.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", mp_normal_range(mu, sigma).pdf(x))
6.356352346256452561561561456135 6E-20
```

dist_normal_range.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a central normal range distribution:

$$\mathrm{cdf}_X(x) = k\int_{-\infty}^{\infty} \phi(y)\,(\Phi(y) - \Phi(y-x))^{k-1}\,\mathrm{d}y.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", mp_normal_range(mu, sigma).pdf(x))
6.356352346256452561561561456135 6E-20
```

dist_normal_range.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following a central normal range distribution:

$$\mathrm{sf}_X(x) = 1 - \mathrm{cdf}_X(x) = k\int_{-\infty}^{\infty} \phi(y)\,\left(L_1^k - : cite : t : `L_1 - L_2\right]^{k-1})\,\mathrm{d}y, \quad \text{where}$$

$$L_1 = \Phi(y), \quad L_2 = \Phi(y-x), \quad L_2 \to 0 \text{ for } x \to \infty$$

$$L_1^k - (L_1 - L_2)^k = L_1^k\left(1 - \left(1 - \frac{L_2}{L_1}\right)^k\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", mp_normal_range(mu, sigma).pdf(x))
sf: 6.356352346256452561561561456135 6E-20
```

dist_normal_range.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following a central normal range distribution:

There is no known explicit form for the quantile function $\text{qtf}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", mp_normal_range(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_normal_range.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following a central normal range distribution:

There is no known explicit form for the quantile function $\text{isf}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", mp_normal_range(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_normal_range.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a central normal range distribution:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \text{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_normal_range(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_normal_range.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a central normal range distribution:

$$M_X(t) = \int_0^\infty e^{tx} \text{pdf}_X(x) \text{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_normal_range(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_normal_range.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a central normal range distribution:

$$K_X(t) = \log\left(M_X(t)\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_normal_range(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

dist_normal_range.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \dots k$, of a random variable X, following a central normal range distribution. The rth moments only exists for $n_2 > 2r$.

$$\mu'_X(r) = E(X^r) = \int_0^\infty x^r \mathrm{pdf}_X(x) \mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_normal_range(mu, sigma).moments(k))
6.356352346256452561561561561456 1356E+00
```

dist_normal_range.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \dots k$, of a random variable X, following a central normal range distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_normal_range(mu, sigma).cumulants(k))
6.356352346256452561561561561456 1356E+00
```

Additional information

$$Q(x) = k \int_{-\infty}^{\infty} \phi(y) \left(\Phi(y) - \Phi(y - x)\right)^{k-1} \mathrm{d}y$$

$$P(x) = 1 - Q(x) = k \int_{-\infty}^{\infty} \phi(y) \left(L_1^k - : cite : t : `L_1 - L_2]^{k-1}\right) \mathrm{d}y, \quad \text{where}$$

$$L_1 = \Phi(y), \quad L_2 = \Phi(y - x), \quad L_2 \to 0 \text{ for } x \to \infty$$

$$L_1^k - (L_1 - L_2)^k = L_1^k \left(1 - \left(1 - \frac{L_2}{L_1}\right)^k\right)$$

4.10.7 Studentized maximum distribution

class ctx.**dist_smax**(*k*, *nu*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The studentized maximum distribution with $k \geq 1$ groups and ν error degrees of freedom is a continuous distribution with the support interval $(-\infty, +\infty)$. See also Stoline and Ury [508], Hochberg and Tamhane [373], Narula [423], Bechhofer and Dunnett [26], and Hahn and Hendrickson [361].

Let $X_1, \ldots, X_k$ be a random sample of size k from a $\mathcal{N}(0, \sigma^2)$ distribution. Let s^2 be an independent mean square estimate of σ with n degrees of freedom. Then

$$Q = \frac{\max X_j}{s}, \quad j = 1, \ldots, k$$

has a Studentized Maximum distribution with k and n degrees of freedom.

dist_smax.**pdf**(*x*)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a studentized maximum distribution:

$$\text{pdf}_X(x) = \int_0^\infty f_{\text{nnax}}(sx, k) \cdot s\sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $f_{\text{nnax}}(\cdot, k)$ is the pdf of the normal maximum with k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", smax(mu, sigma).pdf(x))
6.35635234625645256156156145561356E-20
```

dist_smax.**cdf**(*x*)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a studentized maximum distribution:

$$\text{cdf}_X(x) = \int_0^\infty F_{\text{nnax}}(sx, k) \cdot \sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $F_{\text{nnax}}(\cdot, k)$ is the cdf of the normal maximum with k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", smax(mu, sigma).pdf(x))
6.35635234625645256156156145561356E-20
```

dist_smax.**sf**(*x*)

Returns $\text{sf}_X(x)$, the survival function function (sf) of a random variable X, following a studentized maximum distribution:

$$\text{sf}_X(x) = 1 - \int_0^\infty F_{\text{nnax}}(sx, k) \cdot \sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $F_{\text{nnax}}(\cdot, k)$ is the cdf of the normal maximum with k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", smax(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_smax.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following a studentized maximum distribution:

There is no known explicit form for the quantile function $\text{qtf}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", smax(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_smax.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following a studentized maximum distribution:

There is no known explicit form for the quantile function $\text{isf}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", smax(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_smax.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a studentized maximum distribution:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", smax(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_smax.**m_x**(t)

Returns `NaN`, since the moment generating function does not exist.

dist_smax.**k_x**(t, *k=0*)

Returns `NaN`, since the cumulant generating function does not exist.

dist_smax.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a studentized maximum distribution. The rth moments only exists for $n_2 > 2r$.

$$\mu'_X(r) = E(X^r) = \int_0^\infty x^r \text{pdf}_X(x) \text{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", smax(mu, sigma).moments(k))
6.356352346256452561561561561456 1356E+00
```

dist_smax.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a studentized maximum distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", smax(mu, sigma).cumulants(k))
6.356352346256452561561561561456 1356E+00
```

4.10.8 Studentized maximum modulus distribution

class ctx.**dist_smm**(k, *nu*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The studentized maximum modulus distribution with $k \geq 1$ groups and ν error degrees of freedom is a continuous distribution with the support interval $(-\infty, +\infty)$. See also Stoline and Ury [508], Hochberg and Tamhane [373], Narula [423], Bechhofer and Dunnett [26], and Hahn and Hendrickson [361].

Let $X_1, \ldots, X_k$ be a random sample of size k from a $\mathcal{N}(0, \sigma^2)$ distribution. Let s^2 be an independent mean square estimate of σ with n degrees of freedom. Then

$$Q = \frac{\max|X_j|}{s}, \quad j = 1, \ldots, k$$

has a Studentized Maximum Modulus distribution with k and n degrees of freedom.

dist_smm.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a studentized maximum modulus distribution:

$$\mathrm{pdf}_X(x) = \int_0^\infty f_{\mathrm{nmm}}(sx, k) \cdot s\sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $f_{\mathrm{nmm}}(\cdot, k)$ is the pdf of the normal maximum modulus with k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", smm(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_smm.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a studentized maximum modulus distribution:

$$\mathrm{cdf}_X(x) = \int_0^\infty F_{\mathrm{nmm}}(sx, k) \cdot \sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $F_{\mathrm{nmm}}(\cdot, k)$ is the cdf of the normal maximum modulus with k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", smm(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_smm.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following a studentized maximum modulus distribution:

$$\mathrm{sf}_X(x) = 1 - \int_0^\infty F_{\mathrm{nmm}}(sx, k) \cdot \sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $F_{\mathrm{nmm}}(\cdot, k)$ is the cdf of the normal maximum modulus with k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", smm(mu, sigma).pdf(x))
sf: 6.356352346256452561561561561456135 6E-20
```

dist_smm.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following a studentized maximum modulus distribution:

There is no known explicit form for the quantile function $\text{qtf}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", smm(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561456135 6E+00
```

dist_smm.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following a studentized maximum modulus distribution:

There is no known explicit form for the quantile function $\text{isf}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", smm(mu, sigma).isf(q))
6.356352346256452561561561561456135 6E+00
```

dist_smm.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a studentized maximum modulus distribution:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", smm(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_smm.**m_x**(t)

Returns `NaN`, since the moment generating function does not exist.

dist_smm.**k_x**(t, *k=0*)

Returns `NaN`, since the cumulant generating function does not exist.

dist_smm.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a studentized maximum modulus distribution. The rth moments only exists for $n_2 > 2r$.

$$\mu'_X(r) = E(X^r) = \int_0^\infty x^r \mathrm{pdf}_X(x)\mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", smm(mu, sigma).moments(k))
6.35635234625645256156156145613356E+00
```

dist_smm.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a studentized maximum modulus distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", smm(mu, sigma).cumulants(k))
6.35635234625645256156156145613356E+00
```

4.10.9 Distribution of Dunnett's t, one-sided

class ctx.**dist_dunnett1_t**(*rho*, *k*, *nu*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The 1-sided Dunnett t-distribution with common correlation ρ, $k \geq 2$ groups (including control group) and error degrees of freedom ν is a continuous distribution with the support interval $(-\infty, +\infty)$. See also Dunnett [292], Bechhofer and Dunnett [26].

Let $X_1, \ldots, X_k$ be a random sample of size k from a $\mathcal{N}(0, \sigma^2)$ distribution. Let s^2 be an independent mean square estimate of σ with n degrees of freedom. Then

$$Q = \frac{\max(X_1 - X_j)}{s}, \quad 1 < j < k$$

has a onesided Dunnett's t-distribution with k and n degrees of freedom.

For Dunnett's test:

$$\lambda_i = \frac{1}{\sqrt{1 + n_0/n_i}}$$

dist_dunnett1_t.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a 1-sided Dunnett t-distribution:

$$\mathrm{pdf}_X(x) = \int_0^\infty f_{\mathrm{nmax_corr}}(sx, \rho, k) \cdot s\sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $f_{\mathrm{nmax_corr}}(\cdot, \rho, k)$ is the pdf of the normal maximum (equicorrelated case) with common correlation ρ and k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", dunnett1_t(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_dunnett1_t.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a 1-sided Dunnett t-distribution:

$$\mathrm{cdf}_X(x) = \int_0^\infty F_{\mathrm{nmax_corr}}(sx, \rho, k) \cdot \sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $F_{\mathrm{nmax_corr}}(\cdot, \rho, k)$ is the cdf of the normal maximum (equicorrelated case) with common correlation ρ and k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", dunnett1_t(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_dunnett1_t.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following a 1-sided Dunnett t-distribution:

$$\mathrm{sf}_X(x) = 1 - \int_0^\infty F_{\mathrm{nmax_corr}}(sx, \rho, k) \cdot \sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $F_{\mathrm{nmax_corr}}(\cdot, \rho, k)$ is the cdf of the normal maximum (equicorrelated case) with common correlation ρ and k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", dunnett1_t(mu, sigma).pdf(x))
sf: 6.356352346256452561561561561456135 6E-20
```

dist_dunnett1_t.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following a 1-sided Dunnett t-distribution:

There is no known explicit form for the quantile function $\mathrm{qtf}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", dunnett1_t(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561456135 6E+00
```

dist_dunnett1_t.**isf**(q)

Returns $\mathrm{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following a 1-sided Dunnett t-distribution:

There is no known explicit form for the quantile function $\mathrm{isf}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", dunnett1_t(mu, sigma).isf(q))
6.356352346256452561561561561456135 6E+00
```

dist_dunnett1_t.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a 1-sided Dunnett t-distribution:

$$C_X(t) = \int_0^\infty e^{itx} \mathrm{pdf}_X(x) \mathrm{d}x$$

where $U(\cdot)$ denotes the confluent hypergeometric function of the second kind.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dunnett1_t(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_dunnett1_t.**m_x**(*t*)

Returns NaN, since the moment generating function does not exist.

dist_dunnett1_t.**k_x**(*t*, *k=0*)

Returns NaN, since the cumulant generating function does not exist.

dist_dunnett1_t.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a 1-sided Dunnett t-distribution. The rth moments only exists for $n_2 > 2r$.

$$\mu'_X(r) = E(X^r) = \int_0^\infty x^r \mathrm{pdf}_X(x)\mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dunnett1_t(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_dunnett1_t.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a 1-sided Dunnett t-distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dunnett1_t(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.10.10 Distribution of Dunnett's t, two-sided

class ctx.**dist_dunnett2_t**(*rho*, *k*, *nu*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The 2-sided Dunnett t-distribution with common correlation ρ, $k \geq 2$ groups (including control group) and error degrees of freedom ν is a continuous distribution with the support interval $(0, +\infty)$. See also Dunnett [292], Bechhofer and Dunnett [26].

Let $X_1, \ldots, X_k$ be a random sample of size k from a $\mathcal{N}(0, \sigma^2)$ distribution. Let s^2 be an independent mean square estimate of σ with n degrees of freedom. Then

$$Q = \frac{\max|X_1 - X_j|}{s}, \quad 1 < j < k$$

has a twosided Dunnett's $|t|$-distribution with k and n degrees of freedom.

For Dunnett's test:

$$\lambda_i = \frac{1}{\sqrt{1 + n_0/n_i}}$$

dist_dunnett2_t.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a 2-sided Dunnett t-distribution:

$$\mathrm{pdf}_X(x) = \int_0^\infty f_{\mathrm{nmm_corr}}(sx, \rho, k) \cdot s\sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $f_{\mathrm{nmm_corr}}(\cdot, \rho, k)$ is the pdf of the normal maximum modulus (equicorrelated case) with common correlation ρ and k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", dunnett2_t(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_dunnett2_t.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a 2-sided Dunnett t-distribution:

$$\mathrm{cdf}_X(x) = \int_0^\infty F_{\mathrm{nmm_corr}}(sx, \rho, k)\sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $F_{\mathrm{nmm_corr}}(\cdot, \rho, k)$ is the cdf of the normal maximum modulus (equicorrelated case) with common correlation ρ and k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", dunnett2_t(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_dunnett2_t.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following a 2-sided Dunnett t-distribution:

$$\mathrm{sf}_X(x) = 1 - \int_0^\infty F_{\mathrm{nmm_corr}}(sx, \rho, k)\sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $F_{\mathrm{nmm_corr}}(\cdot, \rho, k)$ is the cdf of the normal maximum modulus (equicorrelated case) with common correlation ρ and k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", dunnett2_t(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_dunnett2_t.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following a 2-sided Dunnett t-distribution:

There is no known explicit form for the quantile function $\text{qtf}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", dunnett2_t(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_dunnett2_t.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following a 2-sided Dunnett t-distribution:

There is no known explicit form for the quantile function $\text{isf}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", dunnett2_t(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_dunnett2_t.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a 2-sided Dunnett t-distribution:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \mathrm{d}x$$

where $U(\cdot)$ denotes the confluent hypergeometric function of the second kind.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dunnett2_t(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_dunnett2_t.**m_x**(t)

Returns NaN, since the moment generating function does not exist.

dist_dunnett2_t.**k_x**(t, *k=0*)

Returns NaN, since the cumulant generating function does not exist.

dist_dunnett2_t.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a 2-sided Dunnett t-distribution. The rth moments only exists for $n_2 > 2r$.

$$\mu'_X(r) = E(X^r) = \int_0^\infty x^r \text{pdf}_X(x) \text{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dunnett2_t(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_dunnett2_t.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a 2-sided Dunnett t-distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", dunnett2_t(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.10.11 Nair's t-distribution

class ctx.**dist_nair_t**(*rho*, *k*, *nu*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The Nair t-distribution with common correlation ρ, $k \geq 2$ groups (including control group) and error degrees of freedom ν is a continuous distribution with the support interval $(-\infty, +\infty)$. See also Dunnett [292], Bechhofer and Dunnett [26].

Let $X_1, \ldots, X_k$ be a random sample of size k from a $\mathcal{N}(0, \sigma^2)$ distribution. Let s^2 be an independent mean square estimate of σ with n degrees of freedom. Then

$$Q = \frac{\max(X_1 - X_j)}{s}, \quad 1 < j < k$$

has a Nair t-distribution with k and n degrees of freedom.

For Dunnett's test:

$$\lambda_i = \frac{1}{\sqrt{1 + n_0/n_i}}$$

dist_nair_t.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a Nair t-distribution:

$$\text{pdf}_X(x) = \int_0^\infty f_{\text{nmax_corr}}(sx, \rho, k) \cdot s\sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $f_{\text{nmax_corr}}(\cdot, \rho, k)$ is the pdf of the normal maximum (equicorrelated case) with common correlation ρ and k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", nair_t(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_nair_t.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Nair t-distribution:

$$\text{cdf}_X(x) = \int_0^\infty F_{\text{nmax_corr}}(sx, \rho, k) \cdot \sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $F_{\text{nmax_corr}}(\cdot, \rho, k)$ is the cdf of the normal maximum (equicorrelated case) with common correlation ρ and k groups , and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", nair_t(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_nair_t.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function function (sf) of a random variable X, following a Nair t-distribution:

$$\text{sf}_X(x) = 1 - \int_0^\infty F_{\text{nmax_corr}}(sx, \rho, k) \cdot \sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $F_{\text{nmax_corr}}(\cdot, \rho, k)$ is the cdf of the normal maximum (equicorrelated case) with common correlation ρ and k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", nair_t(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_nair_t.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following a Nair t-distribution:

There is no known explicit form for the quantile function $\text{qtf}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", nair_t(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_nair_t.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following a Nair t-distribution:

There is no known explicit form for the quantile function $\text{isf}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;

6.3563523462564525615615615614561356E+00
```

dist_nair_t.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Nair t-distribution:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \mathrm{d}x$$

where $U(\cdot)$ denotes the confluent hypergeometric function of the second kind.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", nair_t(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_nair_t.**m_x**(t)

Returns `NaN`, since the moment generating function does not exist.

dist_nair_t.**k_x**(t, *k=0*)

Returns `NaN`, since the cumulant generating function does not exist.

dist_nair_t.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Nair t-distribution. The rth moments only exists for $n_2 > 2r$.

$$\mu'_X(r) = E(X^r) = \int_0^\infty x^r \text{pdf}_X(x) \text{d}x$$

```
>>> from xlcalcnet import *

>>> print ("saddlepoint: ", nair_t(mu, sigma).cumulants(k))
6.35635234625645256156156145614561356E+00
```

4.10.12 Halperin's t-distribution

class ctx.**dist_halperin_t**(*rho*, *k*, *nu*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The Halperin t-distribution with common correlation ρ, $k \geq 2$ groups (including control group) and error degrees of freedom ν is a continuous distribution with the support interval $(0, +\infty)$. See also Dunnett [292], Bechhofer and Dunnett [26].

Let $X_1, \ldots, X_k$ be a random sample of size k from a $\mathcal{N}(0, \sigma^2)$ distribution. Let s^2 be an independent mean square estimate of σ with n degrees of freedom. Then

$$Q = \frac{\max|X_1 - X_j|}{s}, \quad 1 < j < k$$

has a Halperin $|t|$-distribution with k and n degrees of freedom.

For Dunnett's test:

$$\lambda_i = \frac{1}{\sqrt{1 + n_0/n_i}}$$

dist_halperin_t.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a Halperin t-distribution:

$$\mathrm{pdf}_X(x) = \int_0^\infty f_{\mathrm{nmm_corr}}(sx, \rho, k) \cdot s\sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $f_{\mathrm{nmm_corr}}(\cdot, \rho, k)$ is the pdf of the normal maximum modulus (equicorrelated case) with common correlation ρ and k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", halperin_t(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_halperin_t.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Halperin t-distribution:

$$\mathrm{cdf}_X(x) = \int_0^\infty F_{\mathrm{nmm_corr}}(sx, \rho, k)\sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $F_{\mathrm{nmm_corr}}(\cdot, \rho, k)$ is the cdf of the normal maximum modulus (equicorrelated case) with common correlation ρ and k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", halperin_t(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_halperin_t.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following a Halperin t-distribution:

$$\mathrm{sf}_X(x) = 1 - \int_0^\infty F_{\mathrm{nmm_corr}}(sx, \rho, k)\sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $F_{\mathrm{nmm_corr}}(\cdot, \rho, k)$ is the cdf of the normal maximum modulus (equicorrelated case) with common correlation ρ and k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", halperin_t(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_halperin_t.**qtf**(*q*)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following a Halperin t-distribution:

There is no known explicit form for the quantile function $\text{qtf}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", halperin_t(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_halperin_t.**isf**(*q*)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following a Halperin t-distribution:

There is no known explicit form for the quantile function $\text{isf}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", halperin_t(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_halperin_t.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Halperin t-distribution:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \mathrm{d}x$$

where $U(\cdot)$ denotes the confluent hypergeometric function of the second kind.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", halperin_t(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_halperin_t.**m_x**(*t*)

Returns `NaN`, since the moment generating function does not exist.

dist_halperin_t.**k_x**(*t*, *k=0*)

Returns `NaN`, since the cumulant generating function does not exist.

dist_halperin_t.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Halperin t-distribution. The rth moments only exists for $n_2 > 2r$.

$$\mu'_X(r) = E(X^r) = \int_0^\infty x^r \mathrm{pdf}_X(x)\mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", halperin_t(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_halperin_t.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a Halperin t-distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", halperin_t(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.10.13 Nelson's h-distribution

class ctx.**dist_nelson_h**(*rho*, *k*, *nu*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The Halperin t-distribution with common correlation ρ, $k \geq 2$ groups (including control group) and error degrees of freedom ν is a continuous distribution with the support interval $(0, +\infty)$. See also Dunnett [292], Bechhofer and Dunnett [26].

Let $X_1, \ldots, X_k$ be a random sample of size k from a $\mathcal{N}(0, \sigma^2)$ distribution. Let s^2 be an independent mean square estimate of σ with n degrees of freedom. Then

$$Q = \frac{\max|X_1 - X_j|}{s}, \quad 1 < j < k$$

has a Halperin $|t|$-distribution with k and n degrees of freedom.

For Dunnett's test:

$$\lambda_i = \frac{1}{\sqrt{1 + n_0/n_i}}$$

dist_nelson_h.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a Halperin t-distribution:

$$\mathrm{pdf}_X(x) = \int_0^\infty f_{\mathrm{nmm_corr}}(sx, \rho, k) \cdot s\sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $f_{\mathrm{nmm_corr}}(\cdot, \rho, k)$ is the pdf of the normal maximum modulus (equicorrelated case) with common correlation ρ and k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", nelson_h(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_nelson_h.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Halperin t-distribution:

$$\mathrm{cdf}_X(x) = \int_0^\infty F_{\mathrm{nmm_corr}}(sx, \rho, k)\sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $F_{\mathrm{nmm_corr}}(\cdot, \rho, k)$ is the cdf of the normal maximum modulus (equicorrelated case) with common correlation ρ and k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", nelson_h(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_nelson_h.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following a Halperin t-distribution:

$$\mathrm{sf}_X(x) = 1 - \int_0^\infty F_{\mathrm{nmm_corr}}(sx, \rho, k)\sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $F_{\mathrm{nmm_corr}}(\cdot, \rho, k)$ is the cdf of the normal maximum modulus (equicorrelated case) with common correlation ρ and k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", nelson_h(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_nelson_h.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following a Halperin t-distribution:

There is no known explicit form for the quantile function $\text{qtf}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", nelson_h(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_nelson_h.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following a Halperin t-distribution:

There is no known explicit form for the quantile function $\text{isf}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", nelson_h(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_nelson_h.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Halperin t-distribution:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \mathrm{d}x$$

where $U(\cdot)$ denotes the confluent hypergeometric function of the second kind.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", nelson_h(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_nelson_h.**m_x**(t)

Returns `NaN`, since the moment generating function does not exist.

dist_nelson_h.**k_x**(t, *k=0*)

Returns `NaN`, since the cumulant generating function does not exist.

dist_nelson_h.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Halperin t-distribution. The rth moments only exists for $n_2 > 2r$.

$$\mu'_X(r) = E(X^r) = \int_0^\infty x^r \text{pdf}_X(x) \text{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", nelson_h(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_nelson_h.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a Halperin t-distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", nelson_h(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.10.14 Studentized range distribution

class ctx.**dist_studentized_range**(*k*, *nu*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The studentized range distribution with $k \geq 2$ groups and error degrees of freedom ν is a continuous distribution with the support interval $(0, +\infty)$. See also Wikipedia [1220], Harter [364], R (Statistical System) [536],

Let $X_1, \ldots, X_k$ be a random sample of size k from a $\mathcal{N}(0, \sigma^2)$ distribution. Let s^2 be an independent mean square estimate of σ with n degrees of freedom. Then

$$Q = \frac{\max|X_i - X_j|}{s}, \quad 1 < i < j < k$$

has a Studentized Range distribution with k and n degrees of freedom.

Let $X_1, \ldots, X_k$ be a random sample of size k from a $\mathcal{N}(0, \sigma^2)$ distribution. Let s^2 be an independent mean square estimate of σ with n degrees of freedom.

Then $Q_n = \max|X_i - X_j|, 1 < i < j < k$, has a Normal Range distribution with k degrees of freedom, and $Q_t = Q_n/s$ has a Studentized Range distribution with k and n degrees of freedom.

dist_studentized_range.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following a central studentized range distribution:

$$\text{pdf}_X(x) = \int_0^\infty f_{\text{nrange}}(sx, k) \cdot s\sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $f_{\text{nrange}}(\cdot, k)$ is the pdf of the normal range with k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", mp_studentized_range(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_studentized_range.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a central studentized range distribution:

$$\text{cdf}_X(x) = \int_0^\infty F_{\text{nrange}}(sx, k) \cdot \sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $F_{\text{nrange}}(\cdot, k)$ is the cdf of the normal range with k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", mp_studentized_range(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_studentized_range.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following a central studentized range distribution:

$$\mathrm{sf}_X(x) = 1 - \int_0^\infty F_{\mathrm{nrange}}(sx, k) \cdot \sqrt{\nu} \cdot f_\chi\left(s\sqrt{\nu}, \nu\right)\, \mathrm{d}s$$

where $F_{\mathrm{nrange}}(\cdot, k)$ is the cdf of the normal range with k groups, and $f_\chi(\cdot, \nu)$ is the pdf of the χ-distribution with ν degrees of freedom.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", mp_studentized_range(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_studentized_range.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following a central studentized range distribution:

There is no known explicit form for the quantile function $\mathrm{qtf}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", mp_studentized_range(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_studentized_range.**isf**(q)

Returns $\mathrm{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following a central studentized range distribution:

There is no known explicit form for the quantile function $\mathrm{isf}_X(x)$: It is computed using Newton iterations with starting values from a central F approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", mp_studentized_range(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_studentized_range.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a central studentized range distribution:

$$C_X(t) = \int_0^\infty e^{itx} \mathrm{pdf}_X(x) \mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mp_studentized_range(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_studentized_range.**m_x**(t)

Returns NaN, since the moment generating function does not exist.

dist_studentized_range.**k_x**(t, *k=0*)

Returns NaN, since the cumulant generating function does not exist.

dist_studentized_range.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a central studentized range distribution. The rth moments only exists for $n_2 > 2r$.

$$\mu'_X(r) = E(X^r) = \int_0^\infty x^r \mathrm{pdf}_X(x)\mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_studentized_range(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_studentized_range.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a central studentized range distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mp_studentized_range(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

4.11 Distributions related to multivariate statistical analysis

4.11.1 Distribution of the sum of the negative logarithms of independent beta variables

class ctx.**dist_logrv_beta_sum**(p, bi, ci)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

A random variable X follows the distribution of the negative logarithm of the product of p beta variables with parameters a_i and b_i if it is defined as $X = -\log(Y)$, where Y follows a beta product distribution with parameters a_i and b_i. The support interval of X is $(0, +\infty)$.

See also Anderson [9], Muirhead [418], Butler [165], Ginzberg [349], pages 92-105, Marques *et al.* [411], Tang and Gupta [514].

dist_logrv_beta_sum.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

The pdf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. The PDF of Y is the inverse Fourier transform of its characteristic function,

$$\mathrm{pdf}_X(x) = \frac{1}{\pi}\int_0^\infty \Re\left(e^{-itx}C_X(t)\right)\mathrm{d}t.$$

where $\Re(z)$ denotes the real part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", fisher_f(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_logrv_beta_sum.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

The cdf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. Gil-Pelaez derived the following inversion formula which requires integration of a real-valued function, only. In particular,

$$\mathrm{cdf}_X(x) = \frac{1}{2} - \frac{1}{\pi}\int_0^\infty \Im\left(\frac{e^{-itx}C_X(t)}{t}\right)\mathrm{d}t.$$

where $\Im(z)$ denotes the imaginary part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", fisher_f(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_logrv_beta_sum.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

The sf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. Gil-Pelaez derived the following inversion formula which requires integration of a real-valued function, only. In particular,

$$\mathrm{sf}_X(x) = \frac{1}{2} + \frac{1}{\pi}\int_0^\infty \Im\left(\frac{e^{-itx}C_X(t)}{t}\right)\mathrm{d}t.$$

where $\Im(z)$ denotes the imaginary part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_f(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_logrv_beta_sum.**qtf**(q)

Returns $\mathrm{qtf}_X(q)$, the quantile function (qtf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

There is no known closed exact form for $\mathrm{qtf}_X(q)$ or $\mathrm{isf}_X(q)$. It is computed with Newton iterations where the starting values are from Nagarsenker's approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_f(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_logrv_beta_sum.**isf**(q)

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

There is no known closed exact form for $\mathrm{isf}_X(q)$ or $\mathrm{isf}_X(q)$. It is computed with Newton iterations where the starting values are from Nagarsenker's approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_logrv_beta_sum.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

$$C_X(t) = \prod_{j=1}^{p} \frac{\Gamma\left((a_j - it)\right)\Gamma\left((a_j + b_j)\right)}{\Gamma\left(a_j\right)\Gamma\left(a_j + b_j - it\right)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_logrv_beta_sum.**m_x**(t)

Returns the moment generating function of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables.

$$M_X(t) = \prod_{j=1}^{p} \frac{\Gamma\left((a_j - t)\right)\Gamma\left((a_j + b_j)\right)}{\Gamma\left(a_j\right)\Gamma\left(a_j + b_j - t\right)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_logrv_beta_sum.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function, and its r^{th} derivatives, $K_X^{(r)}(t), r = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables.

$$K_X(t) = \sum_{j=1}^{p} \log\left(\Gamma(a_j - t)\right) - \log\left(\Gamma(a_j + b_j - t)\right) + \log\left(\Gamma(a_j + b_j)\right) - \log\left(\Gamma(a_j)\right).$$

$$K_X^{(r)}(t) = (-1)^r \sum_{j=1}^{p} \left(\psi^{(r-1)}(a_j - t) - \psi^{(r-1)}(a_j + b_j - t)\right)$$

where $\psi^{(r)}(\cdot)$ is the polygamma function of order r.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_logrv_beta_sum.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_logrv_beta_sum.**cumulants**(k)

Returns the first j cumulants, $\kappa_r, r = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables.

$$\kappa_r = (-1)^r \sum_{j=1}^{p} \left(\psi^{(r-1)}(a_j) - \psi^{(r-1)}(a_j + b_j)\right)$$

where $\psi^{(r)}(\cdot)$ is the polygamma function of order r.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

Approximations

`ctx.`**`beta_product_ecf`**(*x*, *ai*, *bi*, *results='cdf'*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Edgeworth approximation to the pdf, cdf and sf.

`ctx.`**`beta_product_ecf_inv`**(*q*, *ai*, *bi*, *results='qtf'*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Cornish-Fisher approximation to the qtf and isf.

4.11.2 Distribution of the product of independent beta variables

class ctx.**dist_beta_product**(*p*, *bi*, *ci*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The betaproduct distribution is a continuous probability distribution, defined as the product of $p \geq 1$ independent beta variables, which have a beta distribution with b_j and $c_j - b_j$ degrees of freedom, and the support interval $(0, 1)$. See also Anderson [9], Muirhead [418], Butler [165], Ginzberg [349], pages 92-105, Marques *et al.* [411], Tang and Gupta [514].

Text explaining the concepts.

See also Olkin and Press [433], Wilks [1455], Geisser [345], Marques *et al.* [411], Mauchly [412], Coelho *et al.* [180].

dist_beta_product.**pdf**(*x*)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of the product of independent beta variables. The pdf can expressed as a Meijer G function as follows (PhamGia_2008, p. 1702, Ginzberg_2013, p. 97 + 98):

$$\text{pdf}_X(x) = \frac{Ke^{-x/2}}{2\alpha} G^{m,0}_{m,m}\left(\begin{matrix} a_1, \ldots, a_n; a_{n+1} \ldots a_p \\ b_1, \ldots, b_m; b_{m+1} \ldots b_q \end{matrix} \middle| \; e^{\frac{-x}{2\alpha}}\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", beta_product(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_beta_product.**cdf**(*x*)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of the product of independent beta variables. The cdf can expressed as a Meijer G function as follows (PhamGia_2008, p. 1702, Ginzberg_2013, p. 97 + 98):

$$\text{cdf}_X(x) == Ke^{-x/2} G^{m+1,0}_{m+1,m+1}\left(\begin{matrix} a_1, \ldots, a_n; a_{n+1} \ldots a_p \\ b_1, \ldots, b_m; b_{m+1} \ldots b_q \end{matrix} \middle| \; e^{\frac{-x}{2\alpha}}\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", beta_product(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_beta_product.**sf**(*x*)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following the distribution of the product of independent beta variables. The cdf can expressed as a Meijer G function as follows (PhamGia_2008, p. 1702, Ginzberg_2013, p. 97 + 98):

$$\text{sf}_X(x) == 1 - Ke^{-x/2} G^{m+1,0}_{m+1,m+1}\left(\begin{matrix} a_1, \ldots, a_n; a_{n+1} \ldots a_p \\ b_1, \ldots, b_m; b_{m+1} \ldots b_q \end{matrix} \middle| \; e^{\frac{-x}{2\alpha}}\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", beta_product(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_beta_product.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following the distribution of the product of independent beta variables:

There is no known closed form for the quantile function $\text{cdf}_X^{-1}(q)$: It is computed with Newton iterations where the starting values are from Nagarsenker's approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", beta_product(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_beta_product.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of the product of independent beta variables:

There is no known closed form for the quantile function $\text{isf}_X^{-1}(q)$: It is computed with Newton iterations where the starting values are from Nagarsenker's approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", beta_product(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_beta_product.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of the product of independent beta variables:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", beta_product(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_beta_product.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following the distribution of the product of independent beta variables:

$$M_X(t) = \int_0^\infty e^{tx} \text{pdf}_X(x) \mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", beta_product(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

`dist_beta_product.k_x(s, k=0)`

Returns $K_X(s)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(s), j = 1 \ldots k$, of a random variable X, following the distribution of the product of independent beta variables:

$$K_X(s) = \log\left(M_X(t)\right)$$

where $\Gamma_p(\cdot)$ is the multivariate gamma function and $\psi(\cdot)$ is the digamma function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", beta_product(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

`dist_beta_product.moments(k)`

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of the product of independent beta variables:

$$\mu'_X(r) = \prod_{j=1}^{p} \frac{\Gamma(c_j)\Gamma(b_j + h)}{\Gamma(b_j)\Gamma(c_j + h)}, .$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", beta_product(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

`dist_beta_product.cumulants(k)`

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of the product of independent beta variables. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", beta_product(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

Additional information

`ctx.log_beta_prod_gp(k)`

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the pdf, cdf and sf from the characteristic function using the procedure of Gil-Pelaez (see *gil_pelaez_pdf()* and *gil_pelaez_cdf()*).

This uses $U = \log 2W$.

For a large subset of the random variables W defined in in the previous section there exists a power transformation $U = W^{2/N}$, such that

$$\mathrm{E}[U^h] = \prod_{j=1}^{p} \frac{\Gamma(c_j)\Gamma(b_j + h)}{\Gamma(b_j)\Gamma(c_j + h)},$$

i.e. U is distributed as the product of p independent random variables which have a beta distribution with b_j and $c_j - b_j$ degrees of freedom. This allows to specify these distributions in a simpler form, just giving the b_j and c_j. Its density defined on $(0, 1)$

These are functions for which the l.r.t. $M/2$ is distributed as the product of p independent random variables which have a beta distribution with b_j and $c_j - b_j$ degrees of freedom.

The characteristic function has the general form:

$$\phi_{M/2}(t) = \prod_{j=1}^{p} \frac{\Gamma(c_j)\Gamma(b_j - it)}{\Gamma(b_j)\Gamma(c_j - it)}$$

The distribution of the product of independent beta random variables can also be expressed as a Box-Davis distribution of the Box type with the following parameter choices for a, b, x_k, ξ_k, y_j and η_j:

$$a = b = p, \quad x_k = y_j = N/2, \quad \xi_k = b_k - N/2, \quad \eta_j = c_j - N/2, \quad j, k = 1 \ldots p,$$

`ctx.beta_prod_spa(`*x*, *n*, *results='c'*`)`

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the Luggannini-Rice saddlepoint approximation of the pdf, cdf and sf.

This uses $2 \log W$.

Returns $K_X(s)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(s), j = 1 \ldots k$, of a random variable X, following the distribution of`2log W` of central Wilks W:

$$K_X(s) = \log \left[\frac{\Gamma_p(n/2 + s)\Gamma_p((n+m)/2)}{\Gamma_p(n/2)\Gamma_p((n+m)/2 + s)} \right].$$

$$K'(s) = \sum_{i=1}^{p} \left[\psi\left(\tfrac{1}{2}n + s - \tfrac{1}{2}(i-1)\right) - \psi\left(\tfrac{1}{2}(n+m) + s - \tfrac{1}{2}(i-1)\right) \right]$$

where $\Gamma_p(\cdot)$ is the multivariate gamma function and $\psi(\cdot)$ is the digamma function.

`ctx.beta_prod_spa_inv(`*x*, *n*, *results='qtf'*`)`

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

This uses $2 \log W$.

`ctx.beta_product_bd(`*x*, *f*, *rho*, *omega*`)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Box-Davis approximation to the pdf, cdf and sf.

$$f = -2 \sum_{j=1}^{p} (b_j - c_j); \quad \theta = \frac{N}{2};$$

$$\rho = 1 - \frac{1}{f \cdot \theta} \sum_{j=1}^{p} \big(B_2(b_j - \theta) - B_2(c_j - \theta) \big)$$

$$\omega_r = \frac{(-1)^{r+1}}{r(r+1)(\rho\theta)^r} \sum_{j=1}^{p} \big(B_{r+1}(b_j - \rho\theta) - B_{r+1}(c_j - \rho\theta) \big)$$

`ctx.beta_product_bd_inv(`*q*, *f*, *rho*, *omega*`)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Box-Davis approximation to the qtf and isf.

ctx.**beta_product_bd_cdf_old**(*x*, *f*, *rho*, *omega*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Box-Davis approximation to the pdf, cdf and sf.

For the product-of-independent-beta-variates distributions, the parameters of the Box-Davis expansion are given in equations ....

The distribution of the product of independent beta random variables can also be expressed as a Box-Davis distribution of the Box type with the following parameter choices for a, b, x_k, ξ_k, y_j and η_j:

$$a = b = p, \quad x_k = y_j = N/2, \quad \xi_k = b_k - N/2, \quad \eta_j = c_j - N/2, \quad j, k = 1 \ldots p,$$

$$\theta = \min_{i,j}(x_i, y_j),$$

$$f = -2\left[\sum_{k=1}^{a} \xi_k - \sum_{j=1}^{b} \eta_j - \tfrac{1}{2}(a-b)\right],$$

$$\rho = 1 - \frac{1}{f}\left[\sum_{k=1}^{a} x_k^{-1}\left(\xi_k^2 - \xi_k + \tfrac{1}{6}\right) - \sum_{j=1}^{b} y_j^{-1}\left(\eta_j^2 - \eta_j + \tfrac{1}{6}\right)\right],$$

$$\omega_r = \frac{(-1)^{r+1}}{r(r+1)}\left[\sum_{k=1}^{a} \frac{B_{r+1}((1-\rho)x_k + \xi_k)}{(\rho x_k)^r} - \sum_{j=1}^{b} \frac{B_{r+1}((1-\rho)y_j + \eta_j)}{(\rho y_j)^r}\right],$$

$$\begin{aligned} \log(K_B) &= \log(K) + \frac{1}{2}(m-k)\log(2\pi) - \frac{f}{2}\log(\rho) \\ &\quad + \sum_{i=1}^{m}\left(x_i + \xi_i - \frac{1}{2}\right)\log(x_i) - \sum_{i=1}^{k}\left(y_i + \eta_i - \frac{1}{2}\right)\log(x_i) \end{aligned} \tag{4.38}$$

4.11.3 Distribution of Wilks' Λ

class ctx.**dist_wilks_lambda**(p, m, n)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The Wilks' Λ distribution is a continuous probability distribution with $p \geq 1$ predictor variables, error degress of freedom $m \geq 1$ and $n \geq 1$, and the support interval $(0, 1)$. See also: Wilks [1453], Anderson [9], Muirhead [418], Butler [165], Pham-Gia [470], Witkovský [1498], Witkovský [1497].

dist_wilks_lambda.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of Wilks' Lambda: The pdf is computed by numerical inversion of the characteristic function or cumulant generating function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", wilks_lambda(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_wilks_lambda.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of Wilks' Lambda: The cdf is computed by numerical inversion of the characteristic function or cumulant generating function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", wilks_lambda(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_wilks_lambda.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following the distribution of Wilks' Lambda:

$$\text{sf}_X(x) = 1 - \text{cdf}_X(x) = \int_x^{\infty} \text{pdf}_X(x)\mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", wilks_lambda(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_wilks_lambda.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following the distribution of Wilks' Lambda:

There is no known closed form for the quantile function $\text{cdf}_X^{-1}(q)$: It is computed with Newton iterations where the starting values are from a central chi-square approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", wilks_lambda(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_wilks_lambda.**isf**(*q*)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of Wilks' Lambda:

$$\text{isf}_X(q) = \text{qtf}_X(1-q) = \text{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", wilks_lambda(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_wilks_lambda.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of Wilks' Lambda:

$$C_X(t) = \frac{\Gamma_p(n/2 - it)\Gamma_p((n+m)/2)}{\Gamma_p(n/2)\Gamma_p((n+m)/2 - it)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", wilks_lambda(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_wilks_lambda.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following the distribution of Wilks' Lambda:

$$M_X(t) = \frac{\Gamma_p(n/2 + s)\Gamma_p((n+m)/2)}{\Gamma_p(n/2)\Gamma_p((n+m)/2 + s)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", wilks_lambda(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_wilks_lambda.**k_x**(*s*, *k=0*)

Returns $K_X(s)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(s), j = 1 \ldots k$, of a random variable X, following the distribution of`2log W` of central Wilks W:

$$K_X(s) = \log\left[\frac{\Gamma_p(n/2 + s)\Gamma_p((n+m)/2)}{\Gamma_p(n/2)\Gamma_p((n+m)/2 + s)}\right].$$

$$K'(s) = \sum_{i=1}^{p}\left[\psi\left(\tfrac{1}{2}n + s - \tfrac{1}{2}(i-1)\right) - \psi\left(\tfrac{1}{2}(n+m) + s - \tfrac{1}{2}(i-1)\right)\right]$$

where $\Gamma_p(\cdot)$ is the multivariate gamma function and $\psi(\cdot)$ is the digamma function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", wilks_lambda(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_wilks_lambda.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of Wilks' Lambda:

$$\mu'_X(r) = \frac{\Gamma_p(n/2+s)\Gamma_p((n+m)/2)}{\Gamma_p(n/2)\Gamma_p((n+m)/2+s)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", wilks_lambda(mu, sigma).moments(k))
6.3563523462564525615615615614561356E+00
```

dist_wilks_lambda.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of Wilks' Lambda The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", wilks_lambda(mu, sigma).cumulants(k))
6.3563523462564525615615615614561356E+00
```

Additional information

Anderson, 2003, p. 651-656

p: # of variables

m = q1 = # of groups

M: n-p+1; N=n+q; n = N-q = degrees of freedom (error)

Tables: Renscher 2002, p.566 - 573

Approximations

ctx.**wilks_lambda_gp**(*x*, *p*, *m*, *k*, *results='cdf'*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

Calculates the pdf, cdf and sf from the characteristic function using the procedure of Gil-Pelaez (see *gil_pelaez_pdf()* and *gil_pelaez_cdf()*).

This uses $U = \log 2W$.

ctx.**wilks_lambda_ecf**(*x*, *p*, *m*, *n*, *results='cdf'*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Edgeworth approximation to the pdf, cdf and sf.

ctx.**wilks_lambda_ecf_inv**(*q*, *p*, *m*, *n*, *results='qtf'*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Cornish-Fisher approximation to the qtf and isf.

ctx.**wilks_lambda_spa**(*(x*, *p*, *n1*, *n2*, *results='c'*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

Calculates the Luggannini-Rice saddlepoint approximation of the pdf, cdf and sf.

This uses $2 \log W$.

ctx.**wilks_lambda_spa_inv**(*x*, *n*, *results='qtf'*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

This uses $2 \log W$.

ctx.**wilks_lambda_bd**(*x*, *f*, *rho*, *omega*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Box-Davis approximation to the pdf.

For the Wilks' Lambda distribution, the parameters of the Box-Davis expansion are given vy

$$f = pq; \quad \rho = 1 - \frac{p+q+1}{2(N-1)},$$

$$\omega_r = \frac{(-2)^r}{r(r+1)\mu^r} \sum_{j=0}^{q-1} B_{r+1}((\beta - j)/2) - B_{r+1}((\beta - p - j)/2), \quad \text{where}$$

$$\beta = \frac{p+q+1}{2}; \quad \mu = N - \frac{p+q+3}{2}.$$

wilks_lambda_bd_inv(*q*, *f*, *rho*, *omega*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Box-Davis approximation to the qtf and isf.

4.11.4 Distribution of Wilks' L_{vc}

class ctx.**dist_wilks_cs**(*p*, *bi*, *ci*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

A random variable X follows the distribution of the negative logarithm of the product of p beta variables with parameters a_i and b_i if it is defined as $X = -\log(Y)$, where Y follows a beta product distribution with parameters a_i and b_i. The support interval of X is $(0, +\infty)$.

See also Wilks [1455], Anderson [9], Muirhead [418], Butler [165], Ginzberg [349], pages 92-105, Marques *et al.* [411], Tang and Gupta [514].

dist_wilks_cs.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

The pdf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. The PDF of Y is the inverse Fourier transform of its characteristic function,

$$\text{pdf}_X(x) = \frac{1}{\pi}\int_0^\infty \Re\left(e^{-itx}C_X(t)\right)\,\mathrm{d}t.$$

where $\Re(z)$ denotes the real part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", fisher_f(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_wilks_cs.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

The cdf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. Gil-Pelaez derived the following inversion formula which requires integration of a real-valued function, only. In particular,

$$\text{cdf}_X(x) = \frac{1}{2} - \frac{1}{\pi}\int_0^\infty \Im\left(\frac{e^{-itx}C_X(t)}{t}\right)\,\mathrm{d}t.$$

where $\Im(z)$ denotes the imaginary part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", fisher_f(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_wilks_cs.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

The sf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. Gil-Pelaez derived the following inversion formula which requires integration of a real-valued function,

only. In particular,

$$\mathrm{sf}_X(x) = \frac{1}{2} + \frac{1}{\pi}\int_0^\infty \Im\left(\frac{e^{-itx}C_X(t)}{t}\right)\mathrm{d}t.$$

where $\Im(z)$ denotes the imaginary part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_f(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_wilks_cs.**qtf**(q)

Returns $\mathrm{qtf}_X(q)$, the quantile function (qtf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

There is no known closed exact form for $\mathrm{qtf}_X(q)$ or $\mathrm{isf}_X(q)$. It is computed with Newton iterations where the starting values are from Nagarsenker's approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_f(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_wilks_cs.**isf**(q)

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

There is no known closed exact form for $\mathrm{isf}_X(q)$ or $\mathrm{isf}_X(q)$. It is computed with Newton iterations where the starting values are from Nagarsenker's approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_wilks_cs.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

$$C_X(t) = \prod_{j=1}^{p} \frac{\Gamma\left((a_j - it)\right)\Gamma\left((a_j + b_j)\right)}{\Gamma\left(a_j\right)\Gamma\left(a_j + b_j - it\right)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_wilks_cs.**m_x**(*t*)

Returns the moment generating function of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables.

$$M_X(t) = \prod_{j=1}^{p} \frac{\Gamma\left((a_j - t)\right)\Gamma\left((a_j + b_j)\right)}{\Gamma\left(a_j\right)\Gamma\left(a_j + b_j - t\right)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_wilks_cs.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function, and its r^{th} derivatives, $K_X^{(r)}(t), r = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables.

$$K_X(t) = \sum_{j=1}^{p} \log\left(\Gamma(a_j - t)\right) - \log\left(\Gamma(a_j + b_j - t)\right) + \log\left(\Gamma(a_j + b_j)\right) - \log\left(\Gamma(a_j)\right).$$

$$K_X^{(r)}(t) = (-1)^r \sum_{j=1}^{p} \left(\psi^{(r-1)}(a_j - t) - \psi^{(r-1)}(a_j + b_j - t)\right)$$

where $\psi^{(r)}(\cdot)$ is the polygamma function of order r.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_wilks_cs.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_wilks_cs.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_r, r = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables.

$$\kappa_r = (-1)^r \sum_{j=1}^{p} \left(\psi^{(r-1)}(a_j) - \psi^{(r-1)}(a_j + b_j)\right)$$

where $\psi^{(r)}(\cdot)$ is the polygamma function of order r.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

4.11.5 Distribution of Wilks' L_{vcm}

class ctx.**dist_wilks_lcm**(p, *bi*, *ci*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

A random variable X follows the distribution of the negative logarithm of the product of p beta variables with parameters a_i and b_i if it is defined as $X = -\log(Y)$, where Y follows a beta product distribution with parameters a_i and b_i. The support interval of X is $(0, +\infty)$.

See also Wilks [1455], Anderson [9], Muirhead [418], Butler [165], Ginzberg [349], pages 92-105, Marques *et al.* [411], Tang and Gupta [514].

dist_wilks_lcm.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

The pdf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. The PDF of Y is the inverse Fourier transform of its characteristic function,

$$\text{pdf}_X(x) = \frac{1}{\pi}\int_0^\infty \Re\left(e^{-itx}C_X(t)\right)\,\mathrm{d}t.$$

where $\Re(z)$ denotes the real part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", fisher_f(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_wilks_lcm.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

The cdf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. Gil-Pelaez derived the following inversion formula which requires integration of a real-valued function, only. In particular,

$$\text{cdf}_X(x) = \frac{1}{2} - \frac{1}{\pi}\int_0^\infty \Im\left(\frac{e^{-itx}C_X(t)}{t}\right)\,\mathrm{d}t.$$

where $\Im(z)$ denotes the imaginary part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", fisher_f(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_wilks_lcm.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

The sf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. Gil-Pelaez derived the following inversion formula which requires integration of a real-valued function,

only. In particular,

$$\mathrm{sf}_X(x) = \frac{1}{2} + \frac{1}{\pi}\int_0^\infty \Im\left(\frac{e^{-itx}C_X(t)}{t}\right)\mathrm{d}t.$$

where $\Im(z)$ denotes the imaginary part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_f(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_wilks_lcm.**qtf**(q)

Returns $\mathrm{qtf}_X(q)$, the quantile function (qtf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

There is no known closed exact form for $\mathrm{qtf}_X(q)$ or $\mathrm{isf}_X(q)$. It is computed with Newton iterations where the starting values are from Nagarsenker's approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_f(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_wilks_lcm.**isf**(q)

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

There is no known closed exact form for $\mathrm{isf}_X(q)$ or $\mathrm{isf}_X(q)$. It is computed with Newton iterations where the starting values are from Nagarsenker's approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_wilks_lcm.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

$$C_X(t) = \prod_{j=1}^{p} \frac{\Gamma\left((a_j - it)\right)\Gamma\left((a_j + b_j)\right)}{\Gamma\left(a_j\right)\Gamma\left(a_j + b_j - it\right)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_wilks_lcm.**m_x**(*t*)

Returns the moment generating function of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables.

$$M_X(t) = \prod_{j=1}^{p} \frac{\Gamma\left((a_j - t)\right)\Gamma\left((a_j + b_j)\right)}{\Gamma\left(a_j\right)\Gamma\left(a_j + b_j - t\right)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.356352346256452561561561561456135 6E+00
```

dist_wilks_lcm.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function, and its r^{th} derivatives, $K_X^{(r)}(t), r = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables.

$$K_X(t) = \sum_{j=1}^{p} \log\left(\Gamma(a_j - t)\right) - \log\left(\Gamma(a_j + b_j - t)\right) + \log\left(\Gamma(a_j + b_j)\right) - \log\left(\Gamma(a_j)\right).$$

$$K_X^{(r)}(t) = (-1)^r \sum_{j=1}^{p} \left(\psi^{(r-1)}(a_j - t) - \psi^{(r-1)}(a_j + b_j - t)\right)$$

where $\psi^{(r)}(\cdot)$ is the polygamma function of order r.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.356352346256452561561561561456135 6E+00
```

dist_wilks_lcm.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.356352346256452561561561561456135 6E+00
```

dist_wilks_lcm.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_r, r = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables.

$$\kappa_r = (-1)^r \sum_{j=1}^{p} \left(\psi^{(r-1)}(a_j) - \psi^{(r-1)}(a_j + b_j)\right)$$

where $\psi^{(r)}(\cdot)$ is the polygamma function of order r.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.35635234625645256156156156145613 56E+00
```

4.11.6 Distribution of Wilks' test of independence of p variates

class ctx.**dist_wilks_ip**(*p*, *bi*, *ci*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

A random variable X follows the distribution of the negative logarithm of the product of p beta variables with parameters a_i and b_i if it is defined as $X = -\log(Y)$, where Y follows a beta product distribution with parameters a_i and b_i. The support interval of X is $(0, +\infty)$.

See also Wilks [1454], Anderson [9], Muirhead [418], Butler [165], Ginzberg [349], pages 92-105, Marques *et al.* [411], Tang and Gupta [514].

dist_wilks_ip.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

The pdf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. The PDF of Y is the inverse Fourier transform of its characteristic function,

$$\text{pdf}_X(x) = \frac{1}{\pi}\int_0^\infty \Re\left(e^{-itx}C_X(t)\right)\,\mathrm{d}t.$$

where $\Re(z)$ denotes the real part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", fisher_f(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_wilks_ip.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

The cdf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. Gil-Pelaez derived the following inversion formula which requires integration of a real-valued function, only. In particular,

$$\text{cdf}_X(x) = \frac{1}{2} - \frac{1}{\pi}\int_0^\infty \Im\left(\frac{e^{-itx}C_X(t)}{t}\right)\,\mathrm{d}t.$$

where $\Im(z)$ denotes the imaginary part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", fisher_f(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_wilks_ip.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

The sf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. Gil-Pelaez derived the following inversion formula which requires integration of a real-valued function,

only. In particular,

$$\mathrm{sf}_X(x) = \frac{1}{2} + \frac{1}{\pi}\int_0^\infty \Im\left(\frac{e^{-itx}C_X(t)}{t}\right)\mathrm{d}t.$$

where $\Im(z)$ denotes the imaginary part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_f(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

`dist_wilks_ip.qtf(`q`)`

Returns $\mathrm{qtf}_X(q)$, the quantile function (qtf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

There is no known closed exact form for $\mathrm{qtf}_X(q)$ or $\mathrm{isf}_X(q)$. It is computed with Newton iterations where the starting values are from Nagarsenker's approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_f(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

`dist_wilks_ip.isf(`q`)`

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

There is no known closed exact form for $\mathrm{isf}_X(q)$ or $\mathrm{isf}_X(q)$. It is computed with Newton iterations where the starting values are from Nagarsenker's approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

`dist_wilks_ip.c_x(`t`)`

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

$$C_X(t) = \prod_{j=1}^{p} \frac{\Gamma\left((a_j - it)\right)\Gamma\left((a_j + b_j)\right)}{\Gamma\left(a_j\right)\Gamma\left(a_j + b_j - it\right)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_wilks_ip.**m_x**(*t*)

Returns the moment generating function of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables.

$$M_X(t) = \prod_{j=1}^{p} \frac{\Gamma\left((a_j - t)\right)\Gamma\left((a_j + b_j)\right)}{\Gamma\left(a_j\right)\Gamma\left(a_j + b_j - t\right)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_wilks_ip.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function, and its r^{th} derivatives, $K_X^{(r)}(t), r = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables.

$$K_X(t) = \sum_{j=1}^{p} \log\left(\Gamma(a_j - t)\right) - \log\left(\Gamma(a_j + b_j - t)\right) + \log\left(\Gamma(a_j + b_j)\right) - \log\left(\Gamma(a_j)\right).$$

$$K_X^{(r)}(t) = (-1)^r \sum_{j=1}^{p} \left(\psi^{(r-1)}(a_j - t) - \psi^{(r-1)}(a_j + b_j - t)\right)$$

where $\psi^{(r)}(\cdot)$ is the polygamma function of order r.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_wilks_ip.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_wilks_ip.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_r, r = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables.

$$\kappa_r = (-1)^r \sum_{j=1}^{p} \left(\psi^{(r-1)}(a_j) - \psi^{(r-1)}(a_j + b_j)\right)$$

where $\psi^{(r)}(\cdot)$ is the polygamma function of order r.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

4.11.7 Distribution of Wilks' test of independence of k groups of variates

class ctx.**dist_wilks_iblocks**(*p*, *bi*, *ci*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

A random variable X follows the distribution of the negative logarithm of the product of p beta variables with parameters a_i and b_i if it is defined as $X = -\log(Y)$, where Y follows a beta product distribution with parameters a_i and b_i. The support interval of X is $(0, +\infty)$.

See also Wilks [1454], Anderson [9], Muirhead [418], Butler [165], Ginzberg [349], pages 92-105, Marques *et al.* [411], Tang and Gupta [514].

dist_wilks_iblocks.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

The pdf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. The PDF of Y is the inverse Fourier transform of its characteristic function,

$$\text{pdf}_X(x) = \frac{1}{\pi}\int_0^\infty \Re\left(e^{-itx}C_X(t)\right)\,\mathrm{d}t.$$

where $\Re(z)$ denotes the real part of z.

>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", fisher_f(mu, sigma).pdf(x))
sf: 6.356352346256452561561561561456 1356E-20
```

`dist_wilks_iblocks.qtf(`q`)`

Returns $\mathrm{qtf}_X(q)$, the quantile function (qtf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

There is no known closed exact form for $\mathrm{qtf}_X(q)$ or $\mathrm{isf}_X(q)$. It is computed with Newton iterations where the starting values are from Nagarsenker's approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", fisher_f(mu, sigma).qtf(q))
qtf: 6.356352346256452561561561561456 1356E+00
```

`dist_wilks_iblocks.isf(`q`)`

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

There is no known closed exact form for $\mathrm{isf}_X(q)$ or $\mathrm{isf}_X(q)$. It is computed with Newton iterations where the starting values are from Nagarsenker's approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.356352346256452561561561561456 1356E+00
```

`dist_wilks_iblocks.c_x(`t`)`

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables:

$$C_X(t) = \prod_{j=1}^{p} \frac{\Gamma\left((a_j - it)\right)\Gamma\left((a_j + b_j)\right)}{\Gamma\left(a_j\right)\Gamma\left(a_j + b_j - it\right)}$$

```
>>> from xlcalcnet import *

6.356352346256452561561561561456 1356E+00
```

dist_wilks_iblocks.**m_x**(*t*)

Returns the moment generating function of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables.

$$M_X(t) = \prod_{j=1}^{p} \frac{\Gamma\left((a_j - t)\right)\Gamma\left((a_j + b_j)\right)}{\Gamma\left(a_j\right)\Gamma\left(a_j + b_j - t\right)}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.356352346256452561561561561456135 6E+00
```

dist_wilks_iblocks.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function, and its r^{th} derivatives, $K_X^{(r)}(t), r = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables.

$$K_X(t) = \sum_{j=1}^{p} \log\left(\Gamma(a_j - t)\right) - \log\left(\Gamma(a_j + b_j - t)\right) + \log\left(\Gamma(a_j + b_j)\right) - \log\left(\Gamma(a_j)\right).$$

$$K_X^{(r)}(t) = (-1)^r \sum_{j=1}^{p} \left(\psi^{(r-1)}(a_j - t) - \psi^{(r-1)}(a_j + b_j - t)\right)$$

where $\psi^{(r)}(\cdot)$ is the polygamma function of order r.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.356352346256452561561561561456135 6E+00
```

dist_wilks_iblocks.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.356352346256452561561561561456135 6E+00
```

dist_wilks_iblocks.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_r, r = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables.

$$\kappa_r = (-1)^r \sum_{j=1}^{p} \left(\psi^{(r-1)}(a_j) - \psi^{(r-1)}(a_j + b_j)\right)$$

where $\psi^{(r)}(\cdot)$ is the polygamma function of order r.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.356352346256452561561561561456135 6E+00
```

6.356352346256452561561561561456135 6E+00
```

dist_box_nsame_cov.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.356352346256452561561561561456135 6E+00
```

dist_box_nsame_cov.**cumulants**(k)

Returns the first j cumulants, $\kappa_r, r = 1 \ldots k$, of a random variable X, following the distribution of the negative logarithm of the product of independent beta variables.

$$\kappa_r = (-1)^r \sum_{j=1}^{p} \left(\psi^{(r-1)}(a_j) - \psi^{(r-1)}(a_j + b_j)\right)$$

where $\psi^{(r)}(\cdot)$ is the polygamma function of order r.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", fisher_f(mu, sigma).isf(q))
6.356352346256452561561561561456l356E+00
```

Approximations

`ctx.box_spa`(*x*, *p*, *n1*, *n2*, *results='c'*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the Luggannini-Rice saddlepoint approximation of the pdf, cdf and sf.

This uses $2 \log W$.

Returns $K_X(s)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(s), j = 1 \ldots k$, of a random variable X, following a Box-Davis distribution:

$$K_X(s) = \log \left[\frac{\Gamma_p(n/2 + s)\Gamma_p((n+m)/2)}{\Gamma_p(n/2)\Gamma_p((n+m)/2 + s)} \right].$$

$$K'(s) = \sum_{i=1}^{p} \left[\psi\left(\tfrac{1}{2}n + s - \tfrac{1}{2}(i-1)\right) - \psi\left(\tfrac{1}{2}(n+m) + s - \tfrac{1}{2}(i-1)\right) \right]$$

where $\Gamma_p(\cdot)$ is the multivariate gamma function and $\psi(\cdot)$ is the digamma function.

`ctx.box_spa_inv`(*x*, *n*, *results='qtf'*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

This uses $2 \log W$.

4.11.10 Distribution of Box's test of equality of k covariance matrices, unequal sample sizes

class ctx.**dist_box_cov**(p, k, ni)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of Box's test of equality of k covariance matrices is a continuous probability distribution with $p \geq 1$ predictor variables, error degress of freedom $n_i \geq 1$, and the support interval $(0, 1)$. See also Anderson [9], Muirhead [418], Butler [165], Box [35].

dist_box_cov.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of Box's LRTs.

The pdf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. The PDF of Y is the inverse Fourier transform of its characteristic function,

$$\mathrm{pdf}_X(x) = \frac{1}{\pi}\int_0^\infty \Re\left(e^{-itx}C_X(t)\right)\mathrm{d}t.$$

where $\Re(z)$ denotes the real part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", box_cov(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_box_cov.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of Box's LRTs.

The cdf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. Gil-Pelaez derived the following inversion formula which requires integration of a real-valued function, only. In particular,

$$\mathrm{cdf}_X(x) = \frac{1}{2} - \frac{1}{\pi}\int_0^\infty \Im\left(\frac{e^{-itx}C_X(t)}{t}\right)\mathrm{d}t.$$

where $\Im(z)$ denotes the imaginary part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", box_cov(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_box_cov.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following the distribution of Box's LRTs.

The sf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. Gil-Pelaez derived the following inversion formula which requires integration of a real-valued function, only. In particular,

$$\mathrm{sf}_X(x) = \frac{1}{2} + \frac{1}{\pi}\int_0^\infty \Im\left(\frac{e^{-itx}C_X(t)}{t}\right)\mathrm{d}t.$$

where $\Im(z)$ denotes the imaginary part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", box_cov(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_box_cov.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following the distribution of Box's LRTs:

There is no known closed form for the quantile function $\text{cdf}_X^{-1}(q)$: It is computed with Newton iterations where the starting values are from a central chi-square approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", box_cov(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_box_cov.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of Box's LRTs:

$$\text{isf}_X(q) = \text{qtf}_X(1-q) = \text{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", box_cov(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_box_cov.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of Box's LRTs:

The characteristic function $C_X(t)$ of $M = -2\log(W)$ is given by

$$C_X(t) = K\left(\frac{\prod_{j=1}^{k} 2y_j^{2y_j}}{\prod_{l=1}^{m} 2x_l^{2x_l}}\right)^{-2it} \frac{\prod_{l=1}^{m}\Gamma[x_l(1-2it)+\xi_l]}{\prod_{j=1}^{k}\Gamma[y_j(1-2it)+\eta_j]}, \text{where}$$

$$K = \frac{\prod_{j=1}^{b}\Gamma(y_j+\eta_j)}{\prod_{k=1}^{a}\Gamma(x_k+\xi_k)}, \quad \text{and} \quad \sum_{k=1}^{a} x_k = \sum_{j=1}^{b} y_j.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", box_cov(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_box_cov.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following the distribution of Box's LRTs:

$$M_X(t) = K\left(\frac{\prod_{j=1}^{k} 2y_j^{2y_j}}{\prod_{l=1}^{m} 2x_l^{2x_l}}\right)^{-2t} \frac{\prod_{l=1}^{m}\Gamma[x_l(1-2t)+\xi_l]}{\prod_{j=1}^{k}\Gamma[y_j(1-2t)+\eta_j]}, \text{where}$$

$$K = \frac{\prod_{j=1}^{b} \Gamma(y_j + \eta_j)}{\prod_{k=1}^{a} \Gamma(x_k + \xi_k)}, \quad \text{and} \quad \sum_{k=1}^{a} x_k = \sum_{j=1}^{b} y_j.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", box_cov(mu, sigma).c_x(t))
6.356352346256452561561561456135 6E+00
```

`dist_box_cov.`**`k_x`**`(`*s*, *k=0*`)`

Returns $K_X(t)$, the cumulant generating function, and its j^{th} derivative, $K_X^{(j)}(t), j = 1 \ldots k$, of a random variable X, following the distribution of Box's LRTs:

The cumulant generating function and the j^{th} derivative of the cumulant generating function of $M = -2\log(W)$ are given by

$$K_X(t) = 2\left(\sum_{l=1}^{m} x_l \log(x_l) - \sum_{r=1}^{k} y_r \log(y_r) - \sum_{l=1}^{m} x_l \psi(x_l(1-2t)+\xi_l) + \sum_{r=1}^{k} y_r \psi(y_r(1-2t)+\eta_r)\right), \quad \text{and}$$

$$K_X^{(j)}(t) = \sum_{l=1}^{m} (-2x_l)^j \psi^{(j-1)}(x_l(1-2t)+\xi_l) - \sum_{r=1}^{k} (-2y_r)^j \psi^{(j-1)}(y_r(1-2t)+\eta_r), \quad j \geq 2,$$

where $\psi(\cdot)$ is the digamma function, and its derivatives $\psi^{(j)}(\cdot)$ are polygamma functions.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", box_cov(mu, sigma).k_x(t, k))
6.356352346256452561561561456135 6E+00
```

`dist_box_cov.`**`moments`**`(`*k*`)`

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of Box's LRTs. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", box_cov(mu, sigma).moments(k))
6.356352346256452561561561456135 6E+00
```

`dist_box_cov.`**`cumulants`**`(`*k*`)`

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of Box's LRTs

The cumulants κ_j of $M = -2\log(W)$ are given by

$$\kappa_1 = 2\left(\sum_{l=1}^{m} x_l \log(x_l) - \sum_{r=1}^{k} y_r \log(y_r) - \sum_{l=1}^{m} x_l \psi(x_l+\xi_l) + \sum_{r=1}^{k} y_r \psi(y_r+\eta_r)\right), \quad \text{and}$$

$$\kappa_j = \sum_{l=1}^{m} (-2x_l)^j \psi^{(j-1)}(x_l+\xi_l) - \sum_{r=1}^{k} (-2y_r)^j \psi^{(j-1)}(y_r+\eta_r), \quad j \geq 2,$$

where $\psi(\cdot)$ is the digamma function, and its derivatives $\psi^{(j)}(\cdot)$ are polygamma functions.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", box_cov(mu, sigma).cumulants(k))
6.356352346256452561561561561456135 6E+00
```

Additional information

`ctx.log_box_cov_gp(k)`

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the pdf, cdf and sf from the characteristic function using the procedure of Gil-Pelaez (see *gil_pelaez_pdf()* and *gil_pelaez_cdf()*).

This uses $U = \log 2W$.

In this section we discuss a general class of distributions functions of random variables $M = -2\log(W)$, when the moments of W are products and ratios of gamma functions. W is typically a LRT statistic. M is a special case of the Box-Davis statistic discussed in the previous section.

A random variable $W(0 \leq W \leq 1)$ is said to be of Box type if its h th moment is given by

$$\mathrm{E}[W^h] = K \left(\frac{\prod_{j=1}^{b} y_j^{y_j}}{\prod_{k=1}^{a} x_k^{x_k}} \right)^h \frac{\prod_{k=1}^{a} \Gamma[x_k(1+h)+\xi_k]}{\prod_{j=1}^{b} \Gamma[y_j(1+h)+\eta_j]}, \quad h = 0, 1, \ldots,$$

where $\Gamma(\cdot)$ denotes the gamma function, K is a constant such that $\mathrm{E}[W^0] = 1$, i.e.

$$K = \frac{\prod_{j=1}^{b} \Gamma(y_j+\eta_j)}{\prod_{k=1}^{a} \Gamma(x_k+\xi_k)}, \quad \text{and} \quad \sum_{k=1}^{a} x_k = \sum_{j=1}^{b} y_j.$$

The l.r.t. statistic λ_6 to test the null hypothesis $H_{04} : \Sigma_1 = \ldots = \Sigma_q$, i.e. the equality of q covariance matrices from p-multivariate normal or elliptically contoured distributions is given by

$$\lambda_6 = \frac{n^{np}}{\prod_{k=1}^{q} n_k^{n_k p}} \frac{\prod_{k=1}^{q} |A_k|^{n_k}}{|A|^n}$$

where N_i the sample size in group i, $n_i = N_i - 1, n = \sum_i n_i$, A_k is equal to n_k times the m.l.e. of $\Sigma_k (k = 1, \ldots, q)$, and $A = A_1 + \ldots + A_q$.

The distribution of M can be expressed as a Box-Davis distribution of the Box type with the following parameter choices for a, b, x_k, ξ_k, y_j and η_j:

$$a = pq, \quad b = p, \quad y_j = n/2, \quad \eta_j = (1-j)/2, \quad j = 1 \ldots b$$

$$x_k = n_g/2, \quad \xi_k = (1-i)/2, \quad k = 1 \ldots a = (g-1)p + i, \quad \text{where } g = 1 \ldots q, \quad i = 1 \ldots p$$

For further details, see Anderson_book_2003, pages 419-420.

Now, let $X_k \sim N_p(\mu_k, \Sigma_k)$, for $k = 1, ..., q$. We want to test the hypothesis that the q normal populations are equally distributed. That is, we want to test that the mean vectors μ_k are equal for all $k = 1, ..., q$, as well as the covariance matrices Σ_k are equal for all $k = 1, ..., q$. Then, the null hypothesis is given as

$H_0 : \mu_1 = ... = \mu_q$ and $\Sigma_1 = ... = \Sigma_k$.

Here, the null hypothesis H_0 and the LRT statistic can be decomposed: $\Lambda = \Lambda_{Means} \times \Lambda_{Covariances}$, where (first) $\Lambda_{Covariances}$ represents the LRT for testing equality of covariance matrices of given q normal populations, and (second) Λ_{Means} represents (conditionally) the LRT for testing equality of means of given q normal populations. Under null hypothesis, distributions of $\Lambda_{Covariances}$ and Λ_{Means} are independent, and the distribution of the test statistic Lambda is $\Lambda = \Lambda_{Means} \times \Lambda_{Covariances}$

Let p be the number of variables, q the number of groups, N_i the sample size in group i, $N = \sum_i N_i$. Then the distribution of M can be expressed as a Box-Davis distribution of the Box type with the following parameter choices for a, b, x_k, ξ_k, y_j and η_j:

$$a = pq, \quad b = p \quad y_j = N/2, \quad \eta_j = -j/2, \quad j = 1 \dots b$$

$$x_k = N_g/2, \quad \xi_k = -i/2, \quad k = 1 \dots a = (g-1)p + i, \quad \text{where } g = 1 \dots q, \quad i = 1 \dots p$$

If the sample sizes are the same, the distribution of the test statistic Lambda is

$$\Lambda = \Lambda_{Means} \times \Lambda_{Covariances}, \sim (\prod_{k=1}^{q} \prod_{j=1}^{p} (B_{jk})^{n/2}) \times (\prod_{j=1}^{p} (B_j)^{nq/2})$$

where the B_{jk} and B_j are mutually independent beta distributed random variables. Here we assume that n is equal sample size for each sample, $k = 1, ..., q, n > p$. For further details, see Anderson_book_2003, pages 420-421.

Approximations

`ctx.box_davis_ecf(`*x*, *p*, *k*, *ni*, *results='cdf'*`)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Edgeworth approximation to the pdf, cdf and sf.

`ctx.box_davis_ecf_inv(`*q*, *p*, *k*, *ni*, *results='cdf'*`)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Cornish-Fisher approximation to the qtf and isf.

`ctx.box_cov_bd(`*x*, *f*, *rho*, *omega*`)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Box-Davis approximation to the pdf, cdf and sf.

For Box-type distributions, the parameters of the Box-Davis expansion are given by

Let p be the number of variables, k the number of groups, v_i the sample size in groups i, $N = \sum_i v_i$.

$$\omega = \frac{(-1)^r k}{r(r+1)(r+2)\mu^r} \sum_{s=1}^{r+1} \binom{s+1}{r+2} 2^s \delta_s \gamma_s \beta^{r+1-s}$$

$$\gamma_s = \frac{1}{k} \sum_{i=1}^{k} \left(\frac{v}{v_i}\right)^{s-1} - \frac{1}{k^s}; \quad \text{for equal } v_i : \gamma_s = 1 - \frac{1}{k^s}$$

$$f = \frac{p(p+1)(k-1)}{2}; \quad \rho = \frac{2p^2 + 3p - 1}{6(p+1)(k-1)} \left(-\frac{1}{N} + \sum_{i=1}^{k} \frac{1}{n_i}\right);$$

$$v = \frac{N}{k}; \quad \mu + \rho v = \frac{N\rho}{k}; \quad \beta = (1-\rho)v.$$

Korin (1969), Anderson 1984, p.420

`ctx.box_cov_bd_inv(`*q*, *f*, *rho*, *omega*`)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Box-Davis approximation to the qtf and isf.

4.11.11 Distribution of Box's test for same multivariate normal distributions, unequal sample sizes

class ctx.**dist_box_mvn**(p, k, ni)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of Box's test for same multivariate normal distributions is a continuous probability distribution with $p \geq 1$ predictor variables, error degress of freedom $n_i \geq 1$, and the support interval $(0, 1)$. See also Anderson [9], Muirhead [418], Butler [165], Box [35].

dist_box_mvn.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of Box's LRTs.

The pdf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. The PDF of Y is the inverse Fourier transform of its characteristic function,

$$\mathrm{pdf}_X(x) = \frac{1}{\pi}\int_0^\infty \Re\left(e^{-itx}C_X(t)\right)\mathrm{d}t.$$

where $\Re(z)$ denotes the real part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", box_mvn(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_box_mvn.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of Box's LRTs.

The cdf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. Gil-Pelaez derived the following inversion formula which requires integration of a real-valued function, only. In particular,

$$\mathrm{cdf}_X(x) = \frac{1}{2} - \frac{1}{\pi}\int_0^\infty \Im\left(\frac{e^{-itx}C_X(t)}{t}\right)\mathrm{d}t.$$

where $\Im(z)$ denotes the imaginary part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", box_mvn(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_box_mvn.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following the distribution of Box's LRTs.

The sf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. Gil-Pelaez derived the following inversion formula which requires integration of a real-valued function, only. In particular,

$$\mathrm{sf}_X(x) = \frac{1}{2} + \frac{1}{\pi}\int_0^\infty \Im\left(\frac{e^{-itx}C_X(t)}{t}\right)\mathrm{d}t.$$

where $\Im(z)$ denotes the imaginary part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", box_mvn(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

`dist_box_mvn.qtf(`q`)`

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following the distribution of Box's LRTs:

There is no known closed form for the quantile function $\text{cdf}_X^{-1}(q)$: It is computed with Newton iterations where the starting values are from a central chi-square approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", box_mvn(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

`dist_box_mvn.isf(`q`)`

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of Box's LRTs:

$$\text{isf}_X(q) = \text{qtf}_X(1-q) = \text{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", box_mvn(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

`dist_box_mvn.c_x(`t`)`

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of Box's LRTs:

The characteristic function $C_X(t)$ of $M = -2\log(W)$ is given by

$$C_X(t) = K\left(\frac{\prod_{j=1}^{k} 2y_j^{2y_j}}{\prod_{l=1}^{m} 2x_l^{2x_l}}\right)^{-2it} \frac{\prod_{l=1}^{m}\Gamma[x_l(1-2it)+\xi_l]}{\prod_{j=1}^{k}\Gamma[y_j(1-2it)+\eta_j]}, \text{where}$$

$$K = \frac{\prod_{j=1}^{b}\Gamma(y_j+\eta_j)}{\prod_{k=1}^{a}\Gamma(x_k+\xi_k)}, \quad \text{and} \quad \sum_{k=1}^{a} x_k = \sum_{j=1}^{b} y_j.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", box_mvn(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

`dist_box_mvn.m_x(`t`)`

Returns $M_X(t)$, the moment generating function of a random variable X, following the distribution of Box's LRTs:

$$M_X(t) = K\left(\frac{\prod_{j=1}^{k} 2y_j^{2y_j}}{\prod_{l=1}^{m} 2x_l^{2x_l}}\right)^{-2t} \frac{\prod_{l=1}^{m}\Gamma[x_l(1-2t)+\xi_l]}{\prod_{j=1}^{k}\Gamma[y_j(1-2t)+\eta_j]}, \text{where}$$

$$K = \frac{\prod_{j=1}^{b} \Gamma(y_j + \eta_j)}{\prod_{k=1}^{a} \Gamma(x_k + \xi_k)}, \quad \text{and} \quad \sum_{k=1}^{a} x_k = \sum_{j=1}^{b} y_j.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", box_mvn(mu, sigma).c_x(t))
6.356352346256452561561561456135 6E+00
```

`dist_box_mvn.k_x(s, k=0)`

Returns $K_X(s)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(s), j = 1 \ldots k$, of a random variable X, following the distribution of Box's LRTs:

The cumulant generating function and the j th derivative of the cumulant generating function ` $M = -2\log(W)$ are given by

$$K_X(t) = 2\left(\sum_{i=1}^{m} x_i \log(x_i) - \sum_{r=1}^{k} y_r \log(y_r) - \sum_{l=1}^{m} x_l \psi(x_l(1-2t)+\xi_l) + \sum_{r=1}^{k} y_r \psi(y_r+\eta_r)\right), \quad \text{and}$$

$$K_X^{(j)}(t) = \sum_{i=1}^{m} (-2x_l)^j \psi^{(j-1)}(x_l(1-2t)+\xi_l) - \sum_{r=1}^{k} (-2y_r(1-2t))^j \psi^{(j-1)}(y_r(1-2t)+\eta_r), \quad j \geq 2,$$

where $\psi(\cdot)$ is the digamma function, and its derivatives $\psi^{(j)}(\cdot)$ are polygamma functions.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", box_mvn(mu, sigma).k_x(t, k))
6.356352346256452561561561456135 6E+00
```

`dist_box_mvn.moments(k)`

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of Box's LRTs. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", box_mvn(mu, sigma).moments(k))
6.356352346256452561561561456135 6E+00
```

`dist_box_mvn.cumulants(k)`

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of Box's LRTs

The cumulants κ_j of $M = -2\log(W)$ are given by

$$\kappa_1 = 2\left(\sum_{i=1}^{m} x_i \log(x_i) - \sum_{r=1}^{k} y_r \log(y_r) - \sum_{i=1}^{m} x_i \psi(x_i+\xi_i) + \sum_{r=1}^{k} y_r \psi(y_r+\eta_r)\right), \quad \text{and}$$

$$\kappa_j = \sum_{i=1}^{m} (-2x_i)^j \psi^{(j-1)}(x_i+\xi_i) - \sum_{r=1}^{k} (-2y_r)^j \psi^{(j-1)}(y_r+\eta_r), \quad j \geq 2,$$

where $\psi(\cdot)$ is the digamma function, and its derivatives $\psi^{(j)}(\cdot)$ are polygamma functions.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", box_mvn(mu, sigma).cumulants(k))
6.356352346256452561561561561456135 6E+00
```

Additional information

In this section we discuss a general class of distributions functions of random variables $M = -2\log(W)$, when the moments of W are products and ratios of gamma functions. W is typically a LRT statistic. M is a special case of the Box-Davis statistic discussed in the previous section.

A random variable $W(0 \leq W \leq 1)$ is said to be of Box type if its h th moment is given by

$$\mathrm{E}[W^h] = K\left(\frac{\prod_{j=1}^{b} y_j^{y_j}}{\prod_{k=1}^{a} x_k^{x_k}}\right)^h \frac{\prod_{k=1}^{a}\Gamma[x_k(1+h)+\xi_k]}{\prod_{j=1}^{b}\Gamma[y_j(1+h)+\eta_j]}, \quad h = 0, 1, \ldots,$$

where $\Gamma(\cdot)$ denotes the gamma function, K is a constant such that $\mathrm{E}[W^0] = 1$, i.e.

$$K = \frac{\prod_{j=1}^{b}\Gamma(y_j+\eta_j)}{\prod_{k=1}^{a}\Gamma(x_k+\xi_k)}, \quad \text{and} \quad \sum_{k=1}^{a} x_k = \sum_{j=1}^{b} y_j.$$

The l.r.t. statistic λ_6 to test the null hypothesis $H_{04} : \Sigma_1 = \ldots = \Sigma_q$, i.e. the equality of q covariance matrices from p-multivariate normal or elliptically contoured distributions is given by

$$\lambda_6 = \frac{n^{np}}{\prod_{k=1}^{q} n_k^{n_k p}} \frac{\prod_{k=1}^{q}|A_k|^{n_k}}{|A|^n}$$

where N_i the sample size in group i, $n_i = N_i - 1, n = \sum_i n_i$, A_k is equal to n_k times the m.l.e. of $\Sigma_k (k = 1, \ldots, q)$, and $A = A_1 + \ldots + A_q$.

The distribution of M can be expressed as a Box-Davis distribution of the Box type with the following parameter choices for a, b, x_k, ξ_k, y_j and η_j:

$$a = pq, \quad b = p, \quad y_j = n/2, \quad \eta_j = (1-j)/2, \quad j = 1 \ldots b$$

$$x_k = n_g/2, \quad \xi_k = (1-i)/2, \quad k = 1 \ldots a = (g-1)p + i, \quad \text{where } g = 1 \ldots q, \quad i = 1 \ldots p$$

For further details, see Anderson_book_2003, pages 419-420.

Now, let $X_k \sim N_p(\mu_k, \Sigma_k)$, for $k = 1, ..., q$. We want to test the hypothesis that the q normal populations are equally distributed. That is, we want to test that the mean vectors μ_k are equal for all $k = 1, ..., q$, as well as the covariance matrices Σ_k are equal for all $k = 1, ..., q$. Then, the null hypothesis is given as

$H_0 : \mu_1 = ... = \mu_q$ and $\Sigma_1 = ... = \Sigma_k$.

Here, the null hypothesis H_0 and the LRT statistic can be decomposed: $\Lambda = \Lambda_{Means} \times \Lambda_{Covariances}$, where (first) $\Lambda_{Covariances}$ represents the LRT for testing equality of covariance matrices of given q normal populations, and (second) Λ_{Means} represents (conditionally) the LRT for testing equality of means of given q normal populations. Under null hypothesis, distributions of $\Lambda_{Covariances}$ and Λ_{Means} are independent, and the distribution of the test statistic Lambda is $\Lambda = \Lambda_{Means} \times \Lambda_{Covariances}$

Let p be the number of variables, q the number of groups, N_i the sample size in group i, $N = \sum_i N_i$. Then the distribution of M can be expressed as a Box-Davis distribution of the Box type with the following parameter choices for a, b, x_k, ξ_k, y_j and η_j:

$$a = pq, \quad b = p \quad y_j = N/2, \quad \eta_j = -j/2, \quad j = 1 \ldots b$$

$$x_k = N_g/2, \quad \xi_k = -i/2, \quad k = 1 \ldots a = (g-1)p + i, \quad \text{where } g = 1 \ldots q, \quad i = 1 \ldots p$$

If the sample sizes are the same, the distribution of the test statistic Lambda is

$$\Lambda = \Lambda_{Means} \times \Lambda_{Covariances}, \sim (\prod_{k=1}^{q}\prod_{j=1}^{p}(B_{jk})^{n/2}) \times (\prod_{j=1}^{p}(B_j)^{nq/2})$$

where the B_{jk} and B_j are mutually independent beta distributed random variables. Here we assume that n is equal sample size for each sample, $k = 1, ..., q, n > p$. For further details, see Anderson_book_2003, pages 420-421.

Approximations

`ctx.box_means_cov_bd(`x, f, *rho*, *omega*`)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Box-Davis approximation to the pdf, cdf and sf.

For Box-type distributions, the parameters of the Box-Davis expansion are given by

$$`\theta = \min_{i,j}(x_i, y_j)`,$$

$$f = -2\left[\sum_{k=1}^{a}\xi_k - \sum_{j=1}^{b}\eta_j - \tfrac{1}{2}(a-b)\right],$$

$$\rho = 1 - \frac{1}{f}\left[\sum_{k=1}^{a}x_k^{-1}\left(\xi_k^2 - \xi_k + \tfrac{1}{6}\right) - \sum_{j=1}^{b}y_j^{-1}\left(\eta_j^2 - \eta_j + \tfrac{1}{6}\right)\right],$$

$$\omega_r = \frac{(-1)^{r+1}}{r(r+1)}\left[\sum_{k=1}^{a}\frac{B_{r+1}((1-\rho)x_k + \xi_k)}{(\rho x_k)^r} - \sum_{j=1}^{b}\frac{B_{r+1}((1-\rho)y_j + \eta_j)}{(\rho y_j)^r}\right],$$

$$\begin{aligned}\log(K_B) &= \log(K) + \frac{1}{2}(m-k)\log(2\pi) - \frac{f}{2}\log(\rho) \\ &\quad + \sum_{i=1}^{m}\left(x_i + \xi_i - \frac{1}{2}\right)\log(x_i) - \sum_{i=1}^{k}\left(y_i + \eta_i - \frac{1}{2}\right)\log(x_i)\end{aligned} \tag{4.39}$$

See Siotani p. 356

`ctx.box_means_cov_bd_inv(`q, f, *rho*, *omega*`)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Box-Davis approximation to the qtf and isf.

4.11.12 Distribution of the modified likelihood ratio test (LRT) for a given covariance matrix

`class ctx.dist_lrt_s0(`p, n`)`

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The distribution of the modified (LRT) for a given covariance matrix is a continuous probability distribution with $p \geq 1$ predictor variables, error degress of freedom $n \geq 1$, and the support interval $(0, 1)$. See also Anderson [9], Davis [204].

The modified likelihood criterion λ_1^* for testing the hypothesis that a sample of size N is drawn from a p-variate normal population with a given covariance matrix $\boldsymbol{\Sigma}_0$ is given by

$$\lambda_1^* = e^{\frac{1}{2}pn}\left|\boldsymbol{S}\boldsymbol{\Sigma}_0^{-1}\right|^{\frac{1}{2}n}\exp\left(-\tfrac{1}{2}n\,\mathrm{tr}\left(\boldsymbol{S}\boldsymbol{\Sigma}_0^{-1}\right)\right)$$

where $n = N - 1$ and $\boldsymbol{S}$ is the sample covariance matrix.

`dist_lrt_s0.pdf(`x`)`

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of Box's LRTs.

The pdf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. The PDF of Y is the inverse Fourier transform of its characteristic function,

$$\mathrm{pdf}_X(x) = \frac{1}{\pi}\int_0^\infty \Re\left(e^{-itx}C_X(t)\right)\mathrm{d}t.$$

where $\Re(z)$ denotes the real part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", lrt_s0(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

`dist_lrt_s0.cdf(`x`)`

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of Box's LRTs.

The cdf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. Gil-Pelaez derived the following inversion formula which requires integration of a real-valued function, only. In particular,

$$\mathrm{cdf}_X(x) = \frac{1}{2} - \frac{1}{\pi}\int_0^\infty \Im\left(\frac{e^{-itx}C_X(t)}{t}\right)\mathrm{d}t.$$

where $\Im(z)$ denotes the imaginary part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", lrt_s0(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

`dist_lrt_s0.sf(`x`)`

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following the distribution of Box's LRTs.

The sf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. Gil-Pelaez derived the following inversion formula which requires integration of a real-valued function, only. In particular,

$$\mathrm{sf}_X(x) = \frac{1}{2} + \frac{1}{\pi}\int_0^\infty \Im\left(\frac{e^{-itx}C_X(t)}{t}\right)\mathrm{d}t.$$

where $\Im(z)$ denotes the imaginary part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", lrt_s0(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

`dist_lrt_s0.qtf(`q`)`

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following the distribution of Box's LRTs:

There is no known closed form for the quantile function $\text{cdf}_X^{-1}(q)$: It is computed with Newton iterations where the starting values are from a central chi-square approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", lrt_s0(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

`dist_lrt_s0.isf(`q`)`

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of Box's LRTs:

$$\text{isf}_X(q) = \text{qtf}_X(1-q) = \text{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", lrt_s0(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

`dist_lrt_s0.c_x(`t`)`

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of Box's LRTs:

The characteristic function of $M = -2\log(\lambda_1^*)$ has the form (see Anderson 2003, page 441, equation 16)

$$C_X(t) = \left(\frac{2e}{n}\right)^{-it\cdot pn} (1-2it)^{-\frac{1}{2}pn(1-2it)} \prod_{j=1}^{p} \frac{\Gamma\left[\frac{1}{2}(n+1-j) - it\cdot n\right]}{\Gamma\left[\frac{1}{2}(n+1-j)\right]}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", lrt_s0(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

`dist_lrt_s0.m_x(`t`)`

Returns $M_X(t)$, the moment generating function of a random variable X, following the distribution of Box's LRTs:

$$M_X(t) = \left(\frac{2e}{n}\right)^{-t\cdot pn} (1-2t)^{-\frac{1}{2}pn(1-2t)} \prod_{j=1}^{p} \frac{\Gamma\left[\frac{1}{2}(n+1-j) - t\cdot n\right]}{\Gamma\left[\frac{1}{2}(n+1-j)\right]}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", lrt_s0(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_lrt_s0.**k_x**(*s*, *k=0*)

Returns $K_X(s)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(s), j = 1 \ldots k$, of a random variable X, following the distribution of Box's LRTs:

$$K_X(t) = \log(M_X(t))$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", lrt_s0(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_lrt_s0.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of Box's LRTs. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", lrt_s0(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_lrt_s0.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of Box's LRTs

The cumulants κ_j of $M = -2\log(W)$ are given by

$$\kappa_1 = tbd$$

$$\kappa_j = tbd$$

where $\psi(\cdot)$ is the digamma function, and its derivatives $\psi^{(j)}(\cdot)$ are polygamma functions.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", lrt_s0(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

Additional information

We have for the Box-Davis expansion (see Davis 1971, equations 20-21):

$$f = \tfrac{1}{2}p(p+1); \quad \rho = 1 - \frac{2p^2+3p-1}{6n(p+1)}$$

$$\omega_r = \frac{2(-1)^r}{r(r+1)(r+2)\rho^r} \sum_{s=1}^{r+1} \binom{r+2}{s+1} (1-\rho)^{r+1-s} \frac{\delta_s}{(\frac{1}{2}n)^{s-1}},$$

where δ is defined in Box (1949). For tables see Korin 1968 and Davis 1971.

Approximations

ctx.**lrt_vc0_bd**(q, f, *rho*, *omega*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Box-Davis approximation to the qtf and isf.

The modified likelihood criterion λ_1^* for testing the hypothesis that a sample of size N is drawn from a p-variate normal population with a given covariance matrix $\boldsymbol{\Sigma}_0$ is given by

$$\lambda_1^* = e^{\frac{1}{2}pn} \left|\boldsymbol{S}\boldsymbol{\Sigma}_0^{-1}\right|^{\frac{1}{2}n} \exp\left(-\tfrac{1}{2}n \operatorname{tr}\left(\boldsymbol{S}\boldsymbol{\Sigma}_0^{-1}\right)\right)$$

where $n = N - 1$ and $\boldsymbol{S}$ is the sample covariance matrix.

We have for the Box-Davis expansion (see Davis 1971, equations 20-21):

$$f = \tfrac{1}{2}p(p+1); \quad \rho = 1 - \frac{2p^2 + 3p - 1}{6n(p+1)}; \quad \delta_{s,p} = -\frac{s+1}{2}\sum_{j=0}^{p-1} B_s(-j/2)$$

$$\omega_r = \frac{2(-1)^r}{r(r+1)(r+2)\rho^r} \sum_{s=1}^{r+1} \binom{r+2}{s+1} (1-\rho)^{r+1-s} \frac{\delta_{s,p}}{(\frac{1}{2}n)^{s-1}},$$

where $B_s(\cdot)$ is the Bernoulli polynomial of degree s. For tables see Korin 1968 and Davis 1971.

ctx.**lrt_vc0_bd_inv**(q, f, *rho*, *omega*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Box-Davis approximation to the qtf and isf.

4.11.13 Distribution of the modified likelihood ratio test (LRT) for a given covariance matrix and mean vector

class ctx.**dist_lrt_x0_s0**(p, n)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of the modified (LRT) for a given covariance matrix and mean vector is a continuous probability distribution with $p \geq 1$ predictor variables, error degress of freedom $n \geq 1$, and the support interval $(0, 1)$. See also Anderson [9], Davis [204]. For tables see Nagarsenker 1974

The likelihood criterion λ_2 for testing the hypothesis that a sample of size N is drawn from a p-variate normal population with a given covariance matrix $\boldsymbol{\Sigma}_0$ and mean vector $\boldsymbol{\mu}_0$ is given by

$$\lambda_2 = \left(\frac{e}{N}\right)^{\frac{1}{2}pN} \left|\boldsymbol{S}\boldsymbol{\Sigma}_0^{-1}\right|^{\frac{1}{2}N} \exp\left(-\tfrac{1}{2}\left[\operatorname{tr}\left(\boldsymbol{S}\boldsymbol{\Sigma}_0^{-1}\right) + N(\bar{\boldsymbol{x}} - \boldsymbol{\mu}_0)'\boldsymbol{\Sigma}_0(\bar{\boldsymbol{x}} - \boldsymbol{\mu}_0)\right]\right)$$

where $\boldsymbol{S}$ is the sample covariance matrix and $\bar{\boldsymbol{x}}$ is the sample mean vector.

dist_lrt_x0_s0.**pdf**(x)

Returns $\operatorname{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of Box's LRTs.

The pdf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. The PDF of Y is the inverse Fourier transform of its characteristic function,

$$\operatorname{pdf}_X(x) = \frac{1}{\pi}\int_0^\infty \Re\left(e^{-itx}C_X(t)\right)\mathrm{d}t.$$

where $\Re(z)$ denotes the real part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", lrt_x0_s0(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_lrt_x0_s0.**cdf**(x)

Returns $\operatorname{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of Box's LRTs.

The cdf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. Gil-Pelaez derived the following inversion formula which requires integration of a real-valued function, only. In particular,

$$\operatorname{cdf}_X(x) = \frac{1}{2} - \frac{1}{\pi}\int_0^\infty \Im\left(\frac{e^{-itx}C_X(t)}{t}\right)\mathrm{d}t.$$

where $\Im(z)$ denotes the imaginary part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", lrt_x0_s0(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

`dist_lrt_x0_s0.sf`(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following the distribution of Box's LRTs.

The sf can be calculated (in principle in arbitrary precision) by numerical inversion of the characteristic function, using the algorithm by Gil-Pelaez. Gil-Pelaez derived the following inversion formula which requires integration of a real-valued function, only. In particular,

$$\mathrm{sf}_X(x) = \frac{1}{2} + \frac{1}{\pi}\int_0^\infty \Im\left(\frac{e^{-itx}C_X(t)}{t}\right)\mathrm{d}t.$$

where $\Im(z)$ denotes the imaginary part of z.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", lrt_x0_s0(mu, sigma).pdf(x))
sf: 6.35635234625645256156156156145613 56E-20
```

`dist_lrt_x0_s0.qtf`(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following the distribution of Box's LRTs:

There is no known closed form for the quantile function $\mathrm{cdf}_X^{-1}(q)$: It is computed with Newton iterations where the starting values are from a central chi-square approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", lrt_x0_s0(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156156145613 56E+00
```

`dist_lrt_x0_s0.isf`(q)

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of Box's LRTs:

$$\mathrm{isf}_X(q) = \mathrm{qtf}_X(1-q) = \mathrm{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", lrt_x0_s0(mu, sigma).isf(q))
6.35635234625645256156156156145613 56E+00
```

`dist_lrt_x0_s0.c_x`(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of Box's LRTs:

The characteristic function of $M = -2\log(\lambda_2)$ has the form (Nagarsenker 1974, equation 2.3)

$$C_X(t) = \frac{(2e/N)^{-it\cdot pN}}{(1-2it)^{-\frac{1}{2}pN(1-2it)}}\prod_{j=1}^{p}\frac{\Gamma\left[\frac{1}{2}N(1-2it)-j/2\right]}{\Gamma\left[\frac{1}{2}(N-j)\right]}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", lrt_x0_s0(mu, sigma).c_x(t))
6.35635234625645256156156156145613 56E+00
```

dist_lrt_x0_s0.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following the distribution of Box's LRTs:

$$M_X(t) = \frac{(2e/N)^{-t \cdot pN}}{(1-2t)^{-\frac{1}{2}pN(1-2t)}} \prod_{j=1}^{p} \frac{\Gamma\left[\frac{1}{2}N(1-2t) - j/2\right]}{\Gamma\left[\frac{1}{2}(N-j)\right]}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", lrt_x0_s0(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_lrt_x0_s0.**k_x**(s, *k=0*)

Returns $K_X(s)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(s), j = 1 \ldots k$, of a random variable X, following the distribution of Box's LRTs:

$$M_X(t) = \log(M_X(t))$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", lrt_x0_s0(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_lrt_x0_s0.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of Box's LRTs. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", lrt_x0_s0(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_lrt_x0_s0.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of Box's LRTs

The cumulants κ_j of $M = -2\log(W)$ are given by

$$\kappa_1 = tbd$$

$$\kappa_j = tbd$$

where $\psi(\cdot)$ is the digamma function, and its derivatives $\psi^{(j)}(\cdot)$ are polygamma functions.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", lrt_x0_s0(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

Additional information

We have for the Box-Davis expansion (see Davis 1971, equations 23-24):

$$f = \tfrac{1}{2}p(p+3); \quad \rho = 1 - \frac{2p^2+9p+11}{6N(p+3)}$$

$$\omega_r = \frac{2(-1)^r}{r(r+1)(r+2)\rho^r}\sum_{s=1}^{r+1}\binom{r+2}{s+1}(1-\rho-N^{-1})^{r+1-s}\frac{\delta_s + p(s+1)/2^{s+1}}{(\frac{1}{2}N)^{s-1}},$$

where δ is defined in Box (1949). For tables see Nagarsenker 1974

Approximations

`ctx.`**`lrt_x0_vc0_bd`**`(`q, f, *rho*, *omega*`)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

We have for the Box-Davis expansion (see Davis 1971, equations 23-24):

$$f = \tfrac{1}{2}p(p+3); \quad \rho = 1 - \frac{2p^2+9p+11}{6N(p+3)}; \quad \delta_{s,p} = -\frac{s+1}{2}\sum_{j=0}^{p-1}B_s(-j/2)$$

$$\omega_r = \frac{2(-1)^r}{r(r+1)(r+2)\rho^r}\sum_{s=1}^{r+1}\binom{r+2}{s+1}(1-\rho-N^{-1})^{r+1-s}\frac{\delta_{s,p} + p(s+1)/2^{s+1}}{(\frac{1}{2}N)^{s-1}},$$

where $B_s(\cdot)$ is the Bernoulli polynomial of degree s. . For tables see Nagarsenker 1974

`ctx.`**`lrt_x0_vc0_bd_inv`**`(`q, f, *rho*, *omega*`)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Box-Davis approximation to the qtf and isf.

4.11.14 Central distribution of Roy's largest root

class ctx.**dist_roy**(p, m, n)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of Roy's largest root, with parameters p, m and n, and the support interval $(0, 1)$. See also Anderson [9], Muirhead [418], Butler [165], Chiani [177], Chiani [178].

dist_roy.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of Roy's largest root:

$$\mathrm{pdf}_X(x) = \tfrac{1}{2} C \sqrt{|A(\theta_1)|}\ \mathrm{tr}\left(A(t)^{-1} B\right).$$

A and C are defined as in *roy_pdf_cdf_sf()*.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", roy_largest_root(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_roy.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of Roy's largest root:

$$\mathrm{cdf}_X(x) = C \sqrt{|A(\theta_1)|}.$$

A and C are defined as in *roy_pdf_cdf_sf()*.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", roy_largest_root(mu, sigma).pdf(x))
6.3563523462564525615615615614561356E-20
```

dist_roy.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following the distribution of Roy's largest root:

$$\mathrm{sf}_X(x) = 1 - C \sqrt{|A(\theta_1)|}.$$

A and C are defined as in *roy_pdf_cdf_sf()*.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", roy_largest_root(mu, sigma).pdf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_roy.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following the distribution of Roy's largest root:

There is no known closed form for the quantile function $\mathrm{cdf}_X^{-1}(q)$: It is computed with Newton iterations where the starting values are from a central chi-square approximation by Chiani.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", roy_largest_root(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

`dist_roy.isf(`q`)`

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of Roy's largest root:

There is no known closed form for the quantile function $\text{isf}_X^{-1}(q)$: It is computed with Newton iterations where the starting values are from a central chi-square approximation by Chiani.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", roy_largest_root(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

`dist_roy.c_x(`t`)`

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of Roy's largest root:

$$C_X(t) = \int_0^\infty e^{itx} \text{pdf}_X(x) \mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", roy_largest_root(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

`dist_roy.m_x(`t`)`

Returns $M_X(t)$, the moment generating function of a random variable X, following the distribution of Roy's largest root:

$$M_X(t) = \int_0^\infty e^{tx} \text{pdf}_X(x) \mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", roy_largest_root(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

`dist_roy.k_x(`s`, `*`k=0`*`)`

Returns $K_X(s)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(s), j = 1 \ldots k$, of a random variable X, following the distribution of Roy's largest root:

$$K_X(t) = \log\left(M_X(t)\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", roy_largest_root(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_roy.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of Roy's largest root:

$$\mu'_X(r) = \int_0^\infty x^r \mathrm{pdf}_X(x)\mathrm{d}x$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", roy_largest_root(mu, sigma).moments(k))
6.356352346256452561561561561456135 6E+00
```

dist_roy.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of Roy's largest root. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", roy_largest_root(mu, sigma).cumulants(k))
6.356352346256452561561561561456135 6E+00
```

4.11.15 Central distribution of Pillai's V

class ctx.**dist_pillai_v**(p, m, n)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The Pillai V distribution is a continuous probability distribution with $p \geq 1$ predictor variables, error degress of freedom $m \geq 1$ and $n \geq 1$, and the support interval $(0, 1)$. See also Anderson [9], Muirhead [418], Butler [165], Davis [202], Davis [203], Davis [204].

dist_pillai_v.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of Pillai's V:

The pdf is computed by numerical inversion of the characteristic function or cumulant generating function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", pillai_v(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_pillai_v.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of Pillai's V:

The cdf is computed by numerical inversion of the characteristic function or cumulant generating function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", pillai_v(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_pillai_v.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following the distribution of Pillai's V:

$$\text{sf}_X(x) = 1 - \text{cdf}_X(x) = \int_x^\infty \text{pdf}_X(x)\text{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", pillai_v(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_pillai_v.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following the distribution of Pillai's V:

There is no known closed form for the quantile function $\text{cdf}_X^{-1}(q)$: It is computed with Newton iterations where the starting values are from a central chi-square approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", pillai_v(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_pillai_v.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of Pillai's V:

$$\text{isf}_X(q) = \text{qtf}_X(1-q) = \text{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", pillai_v(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_pillai_v.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of Pillai's V:

```

```

TO BE CALCULATED VIA RAW MOMENTS

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", pillai_v(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_pillai_v.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following the distribution of Pillai's V:

```
TO BE CALCULATED VIA RAW MOMENTS
```

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", pillai_v(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_pillai_v.**k_x**(s, *k=0*)

Returns $K_X(s)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(s), j = 1 \ldots k$, of a random variable X, following the distribution of Pillai's V:

```

```

TO BE CALCULATED VIA RAW MOMENTS

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", pillai_v(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_pillai_v.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of Pillai's V:

```
TO BE CALCULATED AS IN DAVIS
```

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", pillai_v(mu, sigma).moments(k))
6.356352346256452561561561561456 1356E+00
```

dist_pillai_v.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of Pillai's V. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", pillai_v(mu, sigma).cumulants(k))
6.356352346256452561561561561456 1356E+00
```

Approximations

ctx.**pillai_v_ecf**(x, p, m, n, *results='cdf'*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Edgeworth approximation to the pdf, cdf and sf.

ctx.**pillai_v_ecf_inv**(q, p, m, n, *results='qtf'*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Cornish-Fisher approximation to the qtf and isf.

ctx.**pillai_v_bd**(x, f, *rho*, *omega*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Box-Davis approximation to the pdf, cdf and sf.

For Pillai's V distribution, the parameters of the Box-Davis expansion are given by

Let $s = 1, \quad k = m + 1, \quad a = 2k + n_1$. Then

$$f = pq; \quad \rho = 1.$$

$$\omega_1 = mn_1k/(2n_2), \quad 2r\omega_r = 2(r-1)\omega_r - 1 - s(1-k/n_2)c_{1,r}, \quad r = 2, 3, \ldots$$

$$c_{0,0} = 1; \quad c_{0,r} = c_{r,0} = 0; \quad (r = 1, 2, \ldots); \quad c_{r,1} = 0 (r = 2, 3, \ldots)$$

$$\begin{aligned} jc_{j,r} &= [(m-j+1)(n_1-j+1)]c_{j-1,r-1} + [(j(2m+n_1-2j+2)+2(r-1))/n2]c_{j,r-1} \\ &+ [(j+1)/n_2 - (j+1)(m-j+1)/n_2^2]c_{j+1,r-1} - [(mn_1+2(r-2)/n_2]c_{j,r-2} \\ &+ (2/n_2)\sum_{i=1}^{r-2} i\omega_i(c_{j,r-i-1} - c_{j,r-i-2}) \end{aligned}$$

ctx.**pillai_v_bd_inv**(q, f, *rho*, *omega*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Box-Davis approximation to the qtf and isf.

4.11.16 Central distribution of Hotelling's T^2

class ctx.**dist_hotelling_t2**(p, m, n)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The Hotelling T^2 distribution is a continuous probability distribution with $p \geq 1$ predictor variables, error degress of freedom $m \geq 1$ and $n \geq 1$, and the support interval $(0, 1)$. See also Anderson [9], Muirhead [418], Butler [165], Davis [202], Davis [203], Davis [204].

dist_hotelling_t2.**pdf**(x)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the distribution of Hotelling's T^2:

The pdf is computed by numerical inversion of the characteristic function or cumulant generating function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", hotelling_t2(mu, sigma).pdf(x))
6.35635234625645256156156145613356E-20
```

dist_hotelling_t2.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of Hotelling's T^2:

The cdf is computed by numerical inversion of the characteristic function or cumulant generating function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", hotelling_t2(mu, sigma).pdf(x))
6.35635234625645256156156145613356E-20
```

dist_hotelling_t2.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following the distribution of Hotelling's T^2:

$$\text{sf}_X(x) = 1 - \text{cdf}_X(x) = \int_x^\infty \text{pdf}_X(x)\text{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", hotelling_t2(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613356E-20
```

dist_hotelling_t2.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following the distribution of Hotelling's T^2:

There is no known closed form for the quantile function $\text{cdf}_X^{-1}(q)$: It is computed with Newton iterations where the starting values are from a central chi-square approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", hotelling_t2(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613356E+00
```

dist_hotelling_t2.**isf**(*q*)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of Hotelling's T^2:

$$\text{isf}_X(q) = \text{qtf}_X(1-q) = \text{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", hotelling_t2(mu, sigma).isf(q))
6.356352346256452561561561456135 6E+00
```

dist_hotelling_t2.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of Hotelling's T^2:

```
TO BE CALCULATED VIA RAW MOMENTS
```

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", hotelling_t2(mu, sigma).c_x(t))
6.356352346256452561561561456135 6E+00
```

dist_hotelling_t2.**m_x**(*t*)

Does not exist

dist_hotelling_t2.**k_x**(*s*, *k=0*)

Does not exist

dist_hotelling_t2.**moments**(*k*)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of Hotelling's T^2:

Returns the first k moments of the Lawley-Hotelling generalized T_0^2 statistic. The moments of Hotelling's T_0^2 exist up to the j^{th}, where j is the largest integer such that $j < \frac{1}{2}(n_2 - m + 1)$. The raw moments are determined as follows (see Davis [202]):

$$E(T^r) = (-1)^r r!(n_1+n_2)! \sum_{k=0}^{m} \frac{l_{kr}}{(m+n_2-k)!}, \quad \text{where}$$

$$\boldsymbol{l_i} = (l_{0i}, \ldots, l_{mi})', \quad a_i = \tfrac{1}{2}(m-i)(n_2-i),$$

$$\boldsymbol{l_0} = \frac{n_2!}{(n_1+n_2)!}(0, \ldots, 0, 1)',$$

$$\boldsymbol{l_r} = \text{diag}\left(\frac{1}{(r-a_0)}, \ldots, \frac{1}{(r-a_m)}\right) \sum_{s=0}^{r-1} \boldsymbol{l_s},$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", hotelling_t2(mu, sigma).moments(k))
6.356352346256452561561561456135 6E+00
```

dist_hotelling_t2.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of Hotelling's T^2. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", hotelling_t2(mu, sigma).cumulants(k))
6.356352346256452561561561561456135 6E+00
```

Approximations

ctx.**hotelling_t2_ecf**(*x*, *p*, *m*, *n*, *results='cdf'*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Edgeworth approximation to the pdf, cdf and sf.

ctx.**hotelling_t2_ecf_inv**(*q*, *p*, *m*, *n*, *results='qtf'*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Cornish-Fisher approximation to the qtf and isf.

ctx.**hotelling_t2_bd**(*x*, *f*, *rho*, *omega*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Box-Davis approximation to the pdf, cdf and sf.

For Hotelling's T^2 distribution, the parameters of the Box-Davis expansion are given vy

The coefficients for the Box-Davis expansion are calculated as follows:

Let $s = -1, \quad k = -n_1, \quad a = 2n_1 + m + 1$. Then

$$f = pq; \quad \rho = 1.$$

$$\omega_1 = mn_1k/(2n_2), \quad 2r\omega_r = 2(r-1)\omega_r - 1 - s(1-k/n_2)c_{1,r}, \quad r = 2, 3, \ldots$$

$$c_{0,0} = 1; \quad c_{0,r} = c_{r,0} = 0; \quad (r = 1, 2, \ldots); \quad c_{r,1} = 0 (r = 2, 3, \ldots)$$

$$\begin{aligned} jc_{j,r} &= [(m-j+1)(n_1-j+1)]c_{j-1,r-1} + [(j(2m+n_1-2j+2)+2(r-1))/n2]c_{j,r-1} \\ &+ [(j+1)/n_2 - (j+1)(m-j+1)/n_2^2]c_{j+1,r-1} - [(mn_1+2(r-2)/n_2]c_{j,r-2} \\ &+ (2/n_2)\sum_{i=1}^{r-2} i\omega_i(c_{j,r-i-1} - c_{j,r-i-2}) \end{aligned}$$

ctx.**hotelling_t2_bd_inv**(*q*, *f*, *rho*, *omega*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Box-Davis approximation to the qtf and isf.

4.11.17 Noncentral Distribution of Wilks' Λ: MANOVA

class ctx.**dist_wilks_lambda_glm**(*p*, *m*, *n*, *omega*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The noncentral Wilks' Λ distribution under the GLM alternative, with $p \geq 1$ predictor variables, error degress of freedom $m \geq 1$ and $n \geq 1$, noncentrality parameter Ω with diagonal entries $\omega_{jj} \in (0, \infty)$ is a continuous probability distribution with the support interval $(0, 1)$. See also Anderson [9], Muirhead [418], Butler [165], Butler and Wood [167], Butler and Wood [168], Fujikoshi [338], Fujikoshi [339], Fujikoshi [340], Lee [405], Lee [406], Walster and Tretter [793], Witkovský [1492].

dist_wilks_lambda_glm.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the noncentral distribution of Wilks' Lambda (GLM): The pdf is computed by numerical inversion of the characteristic function or cumulant generating function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", wilks_lambda_glm(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_wilks_lambda_glm.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the noncentral distribution of Wilks' Lambda (GLM): The cdf is computed by numerical inversion of the characteristic function or cumulant generating function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", wilks_lambda_glm(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_wilks_lambda_glm.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following the noncentral distribution of Wilks' Lambda (GLM):

$$\mathrm{sf}_X(x) = 1 - \mathrm{cdf}_X(x) = \int_x^\infty \mathrm{pdf}_X(x)\mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", wilks_lambda_glm(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_wilks_lambda_glm.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following the noncentral distribution of Wilks' Lambda (GLM):

There is no known closed form for the quantile function $\mathrm{cdf}_X^{-1}(q)$: It is computed with Newton iterations where the starting values are from a central chi-square approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", wilks_lambda_glm(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_wilks_lambda_glm.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the noncentral distribution of Wilks' Lambda (GLM):

$$\text{isf}_X(q) = \text{qtf}_X(1-q) = \text{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", wilks_lambda_glm(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_wilks_lambda_glm.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following the noncentral distribution of Wilks' Lambda (GLM):

$$C_X(t) = \frac{\Gamma_p(n/2-it)\Gamma_p((n+m)/2)}{\Gamma_p(n/2)\Gamma_p((n+m)/2-it)} {}_1F_1\left(-it; \frac{n+m}{2} + -it; -\frac{1}{2}\Omega\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", wilks_lambda_glm(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_wilks_lambda_glm.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following the noncentral distribution of Wilks' Lambda (GLM):

$$M_X(t) = \left[\frac{\Gamma_p(n/2+s)\Gamma_p((n+m)/2)}{\Gamma_p(n/2)\Gamma_p((n+m)/2+s)} {}_1F_1\left(s, \tfrac{1}{2}(n+m)+s, -\tfrac{1}{2}\Omega\right)\right].$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", wilks_lambda_glm(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_wilks_lambda_glm.**k_x**(s, *k=0*)

Returns $K_X(s)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(s), j = 1 \ldots k$, of a random variable X, following the noncentral distribution of Wilks' Lambda (GLM):

$$K_X(s) = \log\left[\frac{\Gamma_p(n/2+s)\Gamma_p((n+m)/2)}{\Gamma_p(n/2)\Gamma_p((n+m)/2+s)} {}_1F_1\left(s, \tfrac{1}{2}(n+m)+s, -\tfrac{1}{2}\Omega\right)\right].$$

$$K'(s) = \sum_{i=1}^{p} \left[\psi\left(\tfrac{1}{2}n + s - \tfrac{1}{2}(i-1)\right) - \psi\left(\tfrac{1}{2}(n+m) + s - \tfrac{1}{2}(i-1)\right)\right] + \frac{\partial}{\partial s} \log\left[{}_1F_1\left(s, \tfrac{1}{2}(n+m) + s, -\tfrac{1}{2}\Omega\right)\right],$$

where $\Gamma_p(\cdot)$ is the multivariate gamma function , $\psi(\cdot)$ is the digamma function , and ${}_1F_1(\cdot, \cdot, X)$ is the confluent hypergeometric function of matrix argument .

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", wilks_lambda_glm(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

`dist_wilks_lambda_glm.`**`moments`**`(`*k*`)`

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the noncentral distribution of Wilks' Lambda (GLM):

$$\mu'_X(r) = \frac{\Gamma_p(n/2 + s)\Gamma_p((n+m)/2)}{\Gamma_p(n/2)\Gamma_p((n+m)/2 + s)} {}_1F_1\left(s; \frac{n+m}{2} + s; -\frac{1}{2}\Omega\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", wilks_lambda_glm(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

`dist_wilks_lambda_glm.`**`cumulants`**`(`*k*`)`

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the noncentral distribution of Wilks' Lambda (GLM) The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", wilks_lambda_glm(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

Approximations

`ctx.`**`wilks_lambda_glm_gp`**`(`*x*, *p*, *m*, *n*, *Omega*, *cdf=True*, *method='default'*`)`

where `ctx` is `dec`, `mpm`, `fpm`, `gmp` or `apm`.

Calculates the pdf, cdf and sf from the characteristic function using the procedure of Gil-Pelaez (see *gil_pelaez_pdf()* and *gil_pelaez_cdf()*).

This uses $U = \log 2W$.

`ctx.`**`wilks_lambda_glm_spa`**`(`*x*, *n*, *results='c'*`)`

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the Luggannini-Rice saddlepoint approximation of the pdf, cdf and sf.

This uses $2 \log W$ of non-central Wilks W

ctx.**wilks_lambda_glm_inv**(*x*, *n*, *results='qtf'*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

This uses $2 \log W$ of non-central Wilks W

4.11.18 Noncentral Distribution of Wilks' Λ: Canonical Correlation

class ctx.**dist_wilks_lambda_corr**(*p1*, *p2*, *n*, *Rho2*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The noncentral Wilks' Λ distribution under the independence alternative, with $p_1 \geq 1$ and $p_2 \geq 1$ groups of variables, error degress of freedom $n \geq 1$, noncentrality parameter P^2 with diagonal entries $\rho_{jj}^2 \in (0, 1)$ is a continuous probability distribution with the support interval $(0, 1)$. See also Anderson [9], Muirhead [418], Butler [165], Butler and Wood [167], Butler and Wood [168], Fujikoshi [338], Fujikoshi [339], Lee [405], Lee [406], Walster and Tretter [793], Witkovský [1485].

dist_wilks_lambda_corr.**pdf**(*x*, *kwargs*)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following the noncentral distribution of Wilks' Lambda (CORR): The pdf is computed by numerical inversion of the characteristic function or cumulant generating function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", wilks_lambda_corr(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_wilks_lambda_corr.**cdf**(*x*, *kwargs*)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the noncentral distribution of Wilks' Lambda (CORR): The cdf is computed by numerical inversion of the characteristic function or cumulant generating function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", wilks_lambda_corr(mu, sigma).pdf(x))
6.35635234625645256156156145613 56E-20
```

dist_wilks_lambda_corr.**sf**(*x*)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following the noncentral distribution of Wilks' Lambda (CORR):

$$\text{sf}_X(x) = 1 - \text{cdf}_X(x) = \int_x^\infty \text{pdf}_X(x)\text{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", wilks_lambda_corr(mu, sigma).pdf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_wilks_lambda_corr.**qtf**(*q*)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following the noncentral distribution of Wilks' Lambda (CORR):

There is no known closed form for the quantile function $\text{cdf}_X^{-1}(q)$: It is computed with Newton iterations where the starting values are from a central chi-square approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", wilks_lambda_corr(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

`dist_wilks_lambda_corr.`**`isf`**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the noncentral distribution of Wilks' Lambda (CORR):

$$\text{isf}_X(q) = \text{qtf}_X(1-q) = \text{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", wilks_lambda_corr(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

`dist_wilks_lambda_corr.`**`c_x`**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following the noncentral distribution of Wilks' Lambda (CORR):

$$C_X(t) = \frac{\Gamma_{p_1}(n/2)\Gamma_{p_1}((n-p_2)/2-it)}{\Gamma_{p_1}(n/2-it)\Gamma_{p_1}((n-p_2)/2)} \times |I_{p_1} - P^2|^{n/2}{}_2F_1\left(\frac{n}{2}, \frac{n}{2}; \frac{n}{2} - it; P^2\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", wilks_lambda_corr(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

`dist_wilks_lambda_corr.`**`m_x`**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following the noncentral distribution of Wilks' Lambda (CORR):

$$M_X(t) = \left[\frac{\Gamma_{p_1}(n/2)\Gamma_{p_1}((n-p_2)/2+s)}{\Gamma_{p_1}(n/2+s)\Gamma_{p_1}((n-p_2)/2)} \times |I_{p_1} - P^2|^{n/2}{}_2F_1\left(\frac{n}{2}, \frac{n}{2}; \frac{n}{2} + s; P^2\right)\right].$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", wilks_lambda_corr(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

`dist_wilks_lambda_corr.`**`k_x`**(s, *k=0*)

Returns $K_X(s)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(s), j = 1 \ldots k$, of a random variable X, following the noncentral distribution of Wilks' Lambda (CORR):

$$K_X(s) = \log\left[\frac{\Gamma_{p_1}(n/2)\Gamma_{p_1}((n-p_2)/2+s)}{\Gamma_{p_1}(n/2+s)\Gamma_{p_1}((n-p_2)/2)} \times |I_{p_1} - P^2|^{n/2}{}_2F_1\left(\frac{n}{2}, \frac{n}{2}; \frac{n}{2} + s; P^2\right)\right].$$

$$K'(s) = \sum_{i=1}^{p} \left[\psi\left(\tfrac{1}{2}n + s - \tfrac{1}{2}(i-1)\right) - \psi\left(\tfrac{1}{2}(n+m) + s - \tfrac{1}{2}(i-1)\right)\right] + \frac{\partial}{\partial s} \log\left[|I_{p_1} - P^2|^{n/2}{}_2F_1\left(\frac{n}{2}, \frac{n}{2}; \frac{n}{2} + s; P^2\right)\right],$$

where $\Gamma_p(\cdot)$ is the multivariate gamma function , $\psi(\cdot)$ is the digamma function , and ${}_2F_1(\cdot, \cdot, X)$ is the Gauss hypergeometric function of matrix argument . The saddlepoint equation needs to be evaluated numerically. Also, the computation of $K''(s)$ is performed using a numerical derivative of $K'(s)$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", wilks_lambda_corr(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

`dist_wilks_lambda_corr.`**`moments`**`(`*k*`)`

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the noncentral distribution of Wilks' Lambda (CORR):

$$\mu'_X(r) = \frac{\Gamma_{p_1}(n/2)\Gamma_{p_1}((n-p_2)/2+s)}{\Gamma_{p_1}(n/2+s)\Gamma_{p_1}((n-p_2)/2)} \times |I_{p_1} - P^2|^{n/2}{}_2F_1\left(\frac{n}{2}, \frac{n}{2}; \frac{n}{2} + s; P^2\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", wilks_lambda_corr(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

`dist_wilks_lambda_corr.`**`cumulants`**`(`*k*`)`

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the noncentral distribution of Wilks' Lambda (CORR) The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", wilks_lambda_corr(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

Approximations

`ctx.`**`wilks_lambda_ind_gp`**`(`*x*, *p1*, *p2*, *n*, *Rho2*, *method='default'*`)`

where `ctx` is `dec`, `mpm`, `fpm`, `gmp` or `apm`.

Calculates the pdf, cdf and sf from the characteristic function using the procedure of Gil-Pelaez (see *gil_pelaez_pdf()* and *gil_pelaez_cdf()*).

This uses $U = \log 2W$.

`ctx.`**`wilks_lambda_ind_spa`**`(`*x*, *n*, *results='c'*`)`

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the Luggannini-Rice saddlepoint approximation of the pdf, cdf and sf.

This uses $2 \log W$ of non-central Wilks W

ctx.**wilks_lambda_ind_spa_inv**(*x*, *n*, *results='qtf'*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

This uses $2 \log W$ of non-central Wilks W

4.12 Miscellaneous continuous distributions

4.12.1 Boost: Kolmogorov-Smirnov distribution (limiting form)

Returns the pdf, cdf, qtf or boost class of a random variable X, following the limiting form of the Kolmogorov distribution with parameters $n > 0$ and the support interval $[0, \infty)$.

!!! The following references need to be updated: !!!

See also Wikipedia [1148], MathWorld [797], BoostMath [51], Ehrhardt [297] (3.9.2).

math53.**kolmogorov_smirnov_pdf**(n, x)

Returns the pdf of the limiting form of the Kolmogorov distribution, for $x \in [0, \infty)$.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("BetaPdf(x, a, b): ", BetaPdf(x, a, b))
>>> print ("dist_beta(a, b).pdf(x): ", dist_beta(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

math53.**kolmogorov_smirnov_cdf**(n, x)

Returns $\mathrm{KF}(x) = 1 - 2\sum_{k=1}^{\infty}(-1)^k e^{-2k^2x^2}$, the CDF of the limiting form of the Kolmogorov distribution, for $x \in [0, \infty)$.

See also Ehrhardt [297] (3.9.14).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("BetaCdf(x, a, b): ", BetaCdf(x, a, b))
>>> print ("dist_beta(a, b).cdf(x): ", dist_beta(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

math53.**kolmogorov_smirnov_qtf**(n, q)

Returns $\mathrm{KF}^{-1}(x)$, the functional inverse of the CDF of the Kolmogorov distribution (limiting form), ie $\mathrm{KF}(\mathrm{KF}^{-1}(x)) = x$.

See also Ehrhardt [297] (3.9.14).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("BetaQtf(q, a, b): ", BetaQtf(q, a, b))
>>> print ("dist_beta(a, b).qtf(q): ", dist_beta(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

CtxBoost.**dist_kolmogorov_smirnov**(a, b)

Returns an `dist_kolmogorov_smirnov` object, which gives access to the functions descibed below:

```
>>> from xlcalcnet import SReal, FReal, ereal, QReal, CReal, OReal
>>> a = 0; b = 1;
>>> Ctx = SReal
>>> dist_beta = Ctx.dist_beta(a, b)
>>> print ("Dist.qtf(q=0.5): ", Dist.qtf(q=0.5))
6.35635234625645256156156145613 56E+00
```

dist_kolmogorov_smirnov.**pdf**(x)

Returns pdf(x), the value of the probability density function of the Kolmogorov distribution (limiting form). See *Ctx.kolmogorov_smirnov_pdf* for formulas and examples.

dist_kolmogorov_smirnov.**cdf**(x)

Returns cdf(x), the value of the cumulative distribution function of the Kolmogorov distribution (limiting form). See *Ctx.kolmogorov_smirnov_cdf* for formulas and examples.

dist_kolmogorov_smirnov.**qtf**(q)

Returns qtf(q), the value of the quantile function of the Kolmogorov distribution (limiting form). See *Ctx.kolmogorov_smirnov_qtf* for formulas and examples.

dist_kolmogorov_smirnov.**sf**(x)

Returns sf(x), the value of the survival function (*Sf*) of the Kolmogorov distribution (limiting form).

```
>>> # continued from above
>>> print ("Dist.sf(x=0.5): ", Dist.qtf(x=0.5))
6.35635234625645256156156145613 56E+00
```

dist_kolmogorov_smirnov.**isf**(q)

Returns isf(q), the value of the inverse survival function (*Isf*) of the Kolmogorov distribution (limiting form).

```
>>> # continued from above
>>> print ("Dist.isf(x=0.5): ", Dist.isf(x=0.5))
6.35635234625645256156156145613 56E+00
```

dist_kolmogorov_smirnov.**hf**(x)

Returns hazard(x), the value of the hazard function (*Hf*) of the Kolmogorov distribution (limiting form).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_kolmogorov_smirnov.**chf**(x)

Returns chf(x), the value of the cumulative hazard function (*Chf*) of the Kolmogorov distribution (limiting form).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_kolmogorov_smirnov.**mode**()

Returns the *mode* of the Kolmogorov distribution (limiting form). Since there is not one unique mode, Nan is returned.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_kolmogorov_smirnov.**median**()

Returns the *median* of the Kolmogorov distribution (limiting form). Calculated as $\frac{1}{2}(a+b)$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_kolmogorov_smirnov.**mean**()

Returns the *mean* (expected value) of the Kolmogorov distribution (limiting form). Calculated as $\frac{1}{2}(a+b)$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_kolmogorov_smirnov.**variance**()

Returns the *variance* of the Kolmogorov distribution (limiting form). Calculated as $\frac{1}{8}(b-a)^2$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_kolmogorov_smirnov.**stdev**()

Returns the *standard deviation* of the Kolmogorov distribution (limiting form). Calculated as $\sqrt{\frac{1}{8}(b-a)^2}$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_kolmogorov_smirnov.**skewness**()

Returns the *skewness* of the Kolmogorov distribution (limiting form). Calculated as 0.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
```

(continues on next page)

(continued from previous page)

```
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_kolmogorov_smirnov.**kurtosis**()

Returns the 'proper' *kurtosis* (normalized fourth moment) of the Kolmogorov distribution (limiting form). Calculated as $3/2$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_kolmogorov_smirnov.**kurtosis_excess**()

Returns the *kurtosis excess* of the Kolmogorov distribution (limiting form). Calculated as $-3/2$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_kolmogorov_smirnov.**support_lower_endpoint**()

Returns the *support* of the Kolmogorov distribution (limiting form) as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_kolmogorov_smirnov.**support_upper_endpoint**()

Returns the *support* of the Kolmogorov distribution (limiting form) as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_kolmogorov_smirnov.**range_lower_endpoint**()

Returns the valid *range* of the Kolmogorov distribution (limiting form) as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_kolmogorov_smirnov.**range_upper_endpoint**()

Returns the valid *range* of the Kolmogorov distribution (limiting form) as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

4.12.2 Boost: Landau Distribution

The Landau distribution is a stable distribution (see Wikipedia [1230]) with the shape parameters $\alpha = 1, \beta = 1$. For simplicity of numerical computation, this paper evaluates as follows assuming location parameter $\mu = 0$, scale parameter $c = 1/\pi/2$, i.e. $p(x) = p(x; \alpha = 1, \beta = 1, \mu = 0, c = \pi/2)$. For other choices of the location parameter μ and scale parameter c there is the relationship

$$p(x_1; \mu_1, c_1) = p\left(x := \frac{x_1 - \mu_1}{c_1} - \frac{2}{\pi}\log(c); \mu := 0, c := 1\right) \cdot \frac{1}{c_1}.$$

The support interval is $(-\infty, +\infty)$.

!!! The following references need to be updated: !!!

See also: https://www.boost.org/doc/libs/1_89_0/libs/math/doc/html/math_toolkit/dist_ref/dists/landau_dist.html

See also: https://en.wikipedia.org/wiki/Landau_distribution

`math53.landau_pdf(mu, c, x)`

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Landau distribution, with $\mu \in \mathbb{R}$, $c > 0$:

$$\mathrm{pdf}_X(x) = \frac{1}{\pi c}\int_0^\infty e^{-t}\cos\left(t\left(\frac{x-\mu}{c}\right) + \frac{2t}{\pi}\log\left(\frac{t}{c}\right)\right)\mathrm{d}t.$$

For $\mu = 0, c = \pi/2$ this simplifies to:

$$\mathrm{pdf}_X(x) = \frac{1}{\pi}\int_0^\infty \frac{\exp(-xt)\sin(\pi t)}{t^t}\mathrm{d}t.$$

`math53.landau_cdf(mu, c, x)`

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Landau distribution.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("StudentTCdf(x, a, b): ", StudentTCdf(x, a, b))
>>> print ("dist_student_t(a, b).cdf(x): ", dist_student_t(a, b).cdf(x))
6.35635234625645256156156145613356E+00
```

`math53.landau_qtf(mu, c, q)`

where `Ctx` is `Math53` or `CtxBoost`.

Returns $\mathrm{qtf}(q)$, the value of the quantile function (*Qtf*) of the Landau distribution.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("StudentTQtf(q, a, b): ", StudentTQtf(q, a, b))
>>> print ("dist_student_t(a, b).qtf(q): ", dist_student_t(a, b).qtf(q))
6.35635234625645256156156145613356E+00
```

class ctx.**dist_landau**(*n1*, *n2*, *lambda*, ***kwargs*)

In probability theory, the Landau distribution is a probability distribution named after Lev Landau. Because of the distribution's "fat" tail, the moments of the distribution, like mean or variance, are undefined. The distribution is a particular case of stable distribution.

These functions return PDF, CDF, and ICDF of the Landau distribution with location a, scale $b > 0$, and the support interval $(-\infty, +\infty)$:

See also: Wikipedia [1226].

dist_landau.**pdf**(x)

Returns $\mathrm{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Landau distribution:

$$\mathrm{pdf}_X(x) = \frac{1}{\pi}\int_0^\infty \Re\left(e^{-itx}C_X(t)\right)\mathrm{d}t. \tag{4.40}$$

$$= \frac{1}{\pi c}\int_0^\infty e^{-t}\cos\left(t\left(\frac{x-\mu}{c}\right)+\frac{2t}{\pi}\log\left(\frac{t}{c}\right)\right)\mathrm{d}t., \tag{4.41}$$

where $\Re(z)$ denotes the real part of z.

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pdf: ", dist_landau(mu, sigma).pdf(x))
6.356352346256452561561561561456135 6E-20
```

dist_landau.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Landau distribution:

$$\mathrm{cdf}_X(x) = \frac{1}{2} - \frac{1}{\pi}\int_0^\infty \Im\left(\frac{e^{-itx}C_X(t)}{t}\right)\mathrm{d}t,$$

where $\Im(z)$ denotes the imaginary part of z.

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", dist_landau(mu, sigma).pdf(x))
6.356352346256452561561561561456135 6E-20
```

dist_landau.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function function (sf) of a random variable X, following an Landau distribution:

$$\mathrm{sf}_X(x) = 1 - \mathrm{cdf}_X(x) = \int_x^\infty \mathrm{pdf}_X(x)\mathrm{d}t.$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", dist_landau(mu, sigma).pdf(x))
sf: 6.356352346256452561561561561456135 6E-20
```

dist_landau.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function function (qtf) of a random variable X, following an Landau distribution:

$$\text{qtf}_X(q) = \text{no closed form.}$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", dist_landau(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_landau.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function function (isf) of a random variable X, following an Landau distribution:

$$\text{isf}_X(q) = \text{qtf}_X(1-q) = \text{cdf}_X^{-1}(1-q).$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", dist_landau(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_landau.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an Landau distribution:

$$C_X(t) = \exp\left(it\mu - \frac{2ict}{\pi}\log|t| - c|t|\right).$$

```
>>> from mpdistrib import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", dist_landau(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_landau.**m_x**(t)

Returns `NaN`, since the moment generating function does not exist.

dist_landau.**k_x**(t, *k=0*)

Returns `NaN`, since the cumulant generating function does not exist.

dist_landau.**moments**(k)

Returns `NaN`, since moments do not exist.

dist_landau.**cumulants**(k)

Returns `NaN`, since cumulants do not exist.

4.12.3 Boost: Holtsmark distribution

The Holtsmark distribution is a stable distribution (see Wikipedia [1230]) with the shape parameters $\alpha = 3/2, \beta = 0$. The Holtsmark distribution is linear with respect to the location parameter μ and scale parameter c.

$$p(x_1; \mu_1, c_1) = p\left(x := \frac{x_1 - \mu_1}{c_1}; \mu := 0, c := 1\right) \cdot \frac{1}{c_1}.$$

The support interval is $(-\infty, +\infty)$.

!!! The following references need to be updated: !!!

See also: https://www.boost.org/doc/libs/1_89_0/libs/math/doc/html/math_toolkit/dist_ref/dists/holtsmark_dist.html

See also: https://en.wikipedia.org/wiki/Holtsmark_distribution

`math53.`**`holtsmark_pdf`**(*mu*, *c*, *x*)

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Holtsmark distribution

$$\text{pdf}_X(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \exp\left(it\mu - |ct|^{3/2}\right) e^{ixt} \mathrm{d}t,$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("FisherFPdf(x, a, b): ", FisherFPdf(x, a, b))
>>> print ("dist_fisher_f(a, b).pdf(x): ", dist_fisher_f(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`holtsmark_cdf`**(*mu*, *c*, *x*)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Holtsmark distribution.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("FisherFCdf(x, a, b): ", FisherFCdf(x, a, b))
>>> print ("dist_fisher_f(a, b).cdf(x): ", dist_fisher_f(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`holtsmark_qtf`**(*mu*, *c*, *q*)

Returns $\text{qtf}(q)$, the value of the quantile function (*Qtf*) of the Holtsmark distribution.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("FisherFQtf(q, a, b): ", FisherFQtf(q, a, b))
>>> print ("dist_fisher_f(a, b).qtf(q): ", dist_fisher_f(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

`CtxBoost.`**`dist_holtsmark`**(*m*, *n*)

Returns an `dist_holtsmark` object, which gives access to the functions descibed below:

```
>>> from xlcalcnet import SReal, FReal, ereal, QReal, CReal, OReal
>>> a = 0; b = 1;
>>> Ctx = SReal
>>> dist_fisher_f = Ctx.dist_fisher_f(a, b)
>>> print ("Dist.qtf(q=0.5): ", Dist.qtf(q=0.5))
6.35635234625645256156156145613 56E+00
```

dist_holtsmark.**pdf**(x)

Returns pdf(x), the value of the probability density function of the Holtsmark distribution. See *Ctx.holtsmark_pdf* for formulas and examples.

dist_holtsmark.**cdf**(x)

Returns cdf(x), the value of the cumulative distribution function of the Holtsmark distribution. See *Ctx.holtsmark_cdf* for formulas and examples.

dist_holtsmark.**qtf**(q)

Returns qtf(q), the value of the quantile function of the Holtsmark distribution. See *Ctx.holtsmark_qtf* for formulas and examples.

dist_holtsmark.**sf**(x)

Returns sf(x), the value of the survival function (*Sf*) of the Holtsmark distribution.

$$\mathrm{sf}(x) = \begin{cases} \mathrm{ibeta}(n/2, m/2, n/(n+mx)), & mx > n, \\ \mathrm{ibetac}(m/2, n/2, mx/(n+mx)) & mx \le n. \end{cases}$$

Here ibeta($\cdot$) denotes the real normalised incomplete beta function (*RealIBeta*), and ibetac($\cdot$) denotes the real normalised complementary incomplete beta function (*RealIBetac*).

```
>>> # continued from above
>>> print ("Dist.sf(x=0.5): ", Dist.qtf(x=0.5))
6.35635234625645256156156145613 56E+00
```

dist_holtsmark.**isf**(q)

Returns isf(q), the value of the inverse survival function (*Isf*) of the Holtsmark distribution.

$$\mathrm{isf}(q) = \frac{nx}{m(1-x)}, \quad \text{where } x = \mathrm{ibetac_inv}(m/2, n/2, q).$$

Here $\mathrm{ibetac_inv}(\cdot)$ denotes the inverse of the real normalised complementary incomplete beta function (*RealIBetacInv*).

```
>>> # continued from above
>>> print ("Dist.isf(x=0.5): ", Dist.isf(x=0.5))
6.35635234625645256156156145613 56E+00
```

dist_holtsmark.**hf**(x)

Returns hazard(x), the value of the hazard function (*Hf*) of the Holtsmark distribution.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_holtsmark.**chf**(x)

Returns chf(x), the value of the cumulative hazard function (*Chf*) of the Holtsmark distribution.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

dist_holtsmark.**mode**()

Returns the *mode* of the Holtsmark distribution. Since there is not one unique mode, Nan is returned.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

dist_holtsmark.**median**()

Returns the *median* of the Holtsmark distribution. Calculated as $\frac{1}{2}(a+b)$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

dist_holtsmark.**mean**()

Returns the *mean* (expected value) of the Holtsmark distribution. Calculated as $\frac{1}{2}(a+b)$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

dist_holtsmark.**variance**()

Returns the *variance* of the Holtsmark distribution. Calculated as $\frac{1}{8}(b-a)^2$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

dist_holtsmark.**stdev**()

Returns the *standard deviation* of the Holtsmark distribution. Calculated as $\sqrt{\frac{1}{8}(b-a)^2}$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
```

(continues on next page)

(continued from previous page)

```
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_holtsmark.**skewness**()

Returns the *skewness* of the Holtsmark distribution. Calculated as 0.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_holtsmark.**kurtosis**()

Returns the 'proper' *kurtosis* (normalized fourth moment) of the Holtsmark distribution. Calculated as $3/2$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_holtsmark.**kurtosis_excess**()

Returns the *kurtosis excess* of the Holtsmark distribution. Calculated as $-3/2$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_holtsmark.**support_lower_endpoint**()

Returns the *support* of the Holtsmark distribution as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_holtsmark.**support_upper_endpoint**()

Returns the *support* of the Holtsmark distribution as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_holtsmark.**range_lower_endpoint**()

Returns the valid *range* of the Holtsmark distribution as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_holtsmark.**range_upper_endpoint**()

Returns the valid *range* of the Holtsmark distribution as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

4.12.4 Boost: Map-Airy distribution

The Map-Airy distribution (or Airy distribution of the 'Map'-type) is a stable distribution (see Wikipedia [1230]) with the shape parameters $\alpha = 3/2, \beta = 1$, which describes the probability distribution of the area under a Brownian excursion over a unit interval. For simplicity of numerical computation, this paper evaluates as follows assuming location parameter $\mu = 0$, scale parameter $c = 1/\sqrt[3]{18}$, i.e. $p(x) = p(x; \alpha = 3/2, \beta = 1, \mu = 0, c = 1/\sqrt[3]{18})$. The Map-Airy distribution is linear with respect to the location parameter μ and scale parameter c.

$$p(x_1; \mu_1, c_1) = p\left(x := \frac{x_1 - \mu_1}{c_1}; \mu := 0, c := 1\right) \cdot \frac{1}{c_1}.$$

The support interval is $(-\infty, +\infty)$:

!!! The following references need to be updated: !!!

See also: https://mathworld.wolfram.com/Map-AiryDistribution.html

math53.**mapairy_pdf**(*mu*, *c*, *x*)

Returns pdf(x), the value of the probability density function (*Pdf*) of the MapAiry distribution:

Boost:

$$\text{pdf}(x) = 2e^{-2x^3/3}\left(x\text{Ai}(x^2) - \text{Ai}'(x^2)\right).$$

Wolfram:

$$\text{pdf}(x) = 2e^{2x^3/3}\left(-x\text{Ai}(x^2) - \text{Ai}'(x^2)\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("StudentTPdf(x, a, b): ", StudentTPdf(x, a, b))
>>> print ("dist_student_t(a, b).pdf(x): ", dist_student_t(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

math53.**mapairy_cdf**(*mu*, *c*, *x*)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the MapAiry distribution:

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("StudentTCdf(x, a, b): ", StudentTCdf(x, a, b))
>>> print ("dist_student_t(a, b).cdf(x): ", dist_student_t(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

math53.**mapairy_qtf**(*mu*, *c*, *q*)

Returns qtf(q), the value of the quantile function (*Qtf*) of the MapAiry distribution:

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("StudentTQtf(q, a, b): ", StudentTQtf(q, a, b))
>>> print ("dist_student_t(a, b).qtf(q): ", dist_student_t(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

CtxBoost.**dist_mapairy**(a, b)

Returns an dist_mapairy object, which gives access to the functions descibed below:

```
>>> from xlcalcnet import SReal, FReal, ereal, QReal, CReal, OReal
>>> a = 0; b = 1;
>>> Ctx = SReal
>>> dist_student_t = Ctx.dist_student_t(a, b)
>>> print ("Dist.qtf(q=0.5): ", Dist.qtf(q=0.5))
6.35635234625645256156156145613 56E+00
```

dist_mapairy.**pdf**(x)

Returns pdf(x), the value of the probability density function of the Map-Airy distribution. See *Ctx.mapairy_pdf* for formulas and examples.

dist_mapairy.**cdf**(x)

Returns cdf(x), the value of the cumulative distribution function of the Map-Airy distribution. See *Ctx.mapairy_cdf* for formulas and examples.

dist_mapairy.**qtf**(q)

Returns qtf(q), the value of the quantile function of the Map-Airy distribution. See *Ctx.mapairy_qtf* for formulas and examples.

dist_mapairy.**sf**(x)

Returns sf(x), the value of the survival function (*Sf*) of the Map-Airy distribution.

$$\mathrm{sf}(x) = \mathrm{cdf}_X(-x)$$

```
>>> # continued from above
>>> print ("Dist.sf(x=0.5): ", Dist.qtf(x=0.5))
6.35635234625645256156156145613 56E+00
```

dist_mapairy.**isf**(q)

Returns isf(q), the value of the inverse survival function (*Isf*) of the Map-Airy distribution.

$$\mathrm{isf}(q) = -\mathrm{qtf}(q).$$

```
>>> # continued from above
>>> print ("Dist.isf(x=0.5): ", Dist.isf(x=0.5))
6.35635234625645256156156145613 56E+00
```

dist_mapairy.**hf**(x)

Returns hazard(x), the value of the hazard function (*Hf*) of the Map-Airy distribution.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_mapairy.**chf**(x)

Returns chf(x), the value of the cumulative hazard function (*Chf*) of the Map-Airy distribution.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_mapairy.**mode**()

Returns the *mode* of the Map-Airy distribution. Since there is not one unique mode, Nan is returned.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_mapairy.**median**()

Returns the *median* of the Map-Airy distribution. Calculated as $\frac{1}{2}(a+b)$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_mapairy.**mean**()

Returns the *mean* (expected value) of the Map-Airy distribution. Calculated as $\frac{1}{2}(a+b)$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_mapairy.**variance**()

Returns the *variance* of the Map-Airy distribution. Calculated as $\frac{1}{8}(b-a)^2$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_mapairy.**stdev**()

Returns the *standard deviation* of the Map-Airy distribution. Calculated as $\sqrt{\frac{1}{8}(b-a)^2}$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_mapairy.**skewness**()

Returns the *skewness* of the Map-Airy distribution. Calculated as 0.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_mapairy.**kurtosis**()

Returns the 'proper' *kurtosis* (normalized fourth moment) of the Map-Airy distribution. Calculated as $3/2$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_mapairy.**kurtosis_excess**()

Returns the *kurtosis excess* of the Map-Airy distribution. Calculated as $-3/2$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_mapairy.**support_lower_endpoint**()

Returns the *support* of the Map-Airy distribution as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_mapairy.**support_upper_endpoint**()

Returns the *support* of the Map-Airy distribution as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_mapairy.**range_lower_endpoint**()

Returns the valid *range* of the Map-Airy distribution as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

dist_mapairy.**range_upper_endpoint**()

Returns the valid *range* of the Map-Airy distribution as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

4.12.5 Boost: Saspoint5 distribution

The SaS point5 distribution is a stable distribution (see Wikipedia [1230]) with the shape parameters $\alpha = 1/2, \beta = 0$. The Saspoint5 distribution is linear with respect to the location parameter μ and scale parameter c.

$$p(x_1; \mu_1, c_1) = p\left(x := \frac{x_1 - \mu_1}{c_1}; \mu := 0, c := 1\right) \cdot \frac{1}{c_1}.$$

The support interval is $(-\infty, +\infty)$.

See also: https://www.boost.org/doc/libs/1_89_0/libs/math/doc/html/math_toolkit/dist_ref/dists/saspoint5_dist.html

See also: https://en.wikipedia.org/wiki/Stable_distribution#Other_analytic_cases

`math53.saspoint5_pdf(mu, c, x)`

Returns $\text{pdf}_X(x)$, the probability density function (pdf) of a random variable X, following an Saspoint5 distribution. Let $S(x)$ and $C(x)$ denote the Fresnel integrals. Then:

$$\text{pdf}_X(x) = \frac{1}{\sqrt{2\pi|x|^3}}\left(\sin\left(\frac{1}{4|x|}\right)\left[\frac{1}{2} - S\left(\frac{1}{\sqrt{2\pi|x|}}\right)\right] + \cos\left(\frac{1}{4|x|}\right)\left[\frac{1}{2} - C\left(\frac{1}{\sqrt{2\pi|x|}}\right)\right]\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("StudentTPdf(x, a, b): ", StudentTPdf(x, a, b))
>>> print ("dist_student_t(a, b).pdf(x): ", dist_student_t(a, b).pdf(x))
6.35635234625645256156156145613356E+00
```

`math53.saspoint5_cdf(mu, c, x)`

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an Saspoint5 distribution.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("StudentTCdf(x, a, b): ", StudentTCdf(x, a, b))
>>> print ("dist_student_t(a, b).cdf(x): ", dist_student_t(a, b).cdf(x))
6.35635234625645256156156145613356E+00
```

`math53.saspoint5_qtf(mu, c, q)`

Returns $\text{qtf}(q)$, the value of the quantile function (*Qtf*) of the Saspoint5 distribution:

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("StudentTQtf(q, a, b): ", StudentTQtf(q, a, b))
>>> print ("dist_student_t(a, b).qtf(q): ", dist_student_t(a, b).qtf(q))
6.35635234625645256156156145613356E+00
```

CtxBoost.**dist_saspoint5**(a, b)

Returns an dist_saspoint5 object, which gives access to the functions descibed below:

```
>>> from xlcalcnet import SReal, FReal, ereal, QReal, CReal, OReal
>>> a = 0; b = 1;
>>> Ctx = SReal
>>> dist_student_t = Ctx.dist_student_t(a, b)
>>> print ("Dist.qtf(q=0.5): ", Dist.qtf(q=0.5))
6.35635234625645256156156145613 56E+00
```

dist_saspoint5.**pdf**(x)

Returns pdf(x), the value of the probability density function of the Saspoint5 distribution. See *Ctx.saspoint5_pdf* for formulas and examples.

dist_saspoint5.**cdf**(x)

Returns cdf(x), the value of the cumulative distribution function of the Saspoint5 distribution. See *Ctx.saspoint5_cdf* for formulas and examples.

dist_saspoint5.**qtf**(q)

Returns qtf(q), the value of the quantile function of the Saspoint5 distribution. See *Ctx.saspoint5_qtf* for formulas and examples.

dist_saspoint5.**sf**(x)

Returns sf(x), the value of the survival function (*Sf*) of the Saspoint5 distribution.

$$\mathrm{sf}(x) = \mathrm{cdf}_X(-x)$$

```
>>> # continued from above
>>> print ("Dist.sf(x=0.5): ", Dist.qtf(x=0.5))
6.35635234625645256156156145613 56E+00
```

dist_saspoint5.**isf**(q)

Returns isf(q), the value of the inverse survival function (*Isf*) of the Saspoint5 distribution.

$$\mathrm{isf}(q) = -\mathrm{qtf}(q).$$

```
>>> # continued from above
>>> print ("Dist.isf(x=0.5): ", Dist.isf(x=0.5))
6.35635234625645256156156145613 56E+00
```

dist_saspoint5.**hf**(x)

Returns hazard(x), the value of the hazard function (*Hf*) of the Saspoint5 distribution.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_saspoint5.**chf**(x)

Returns chf(x), the value of the cumulative hazard function (*Chf*) of the Saspoint5 distribution.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_saspoint5.**mode**()

Returns the *mode* of the Saspoint5 distribution. Since there is not one unique mode, Nan is returned.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_saspoint5.**median**()

Returns the *median* of the Saspoint5 distribution. Calculated as $\frac{1}{2}(a+b)$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_saspoint5.**mean**()

Returns the *mean* (expected value) of the Saspoint5 distribution. Calculated as $\frac{1}{2}(a+b)$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_saspoint5.**variance**()

Returns the *variance* of the Saspoint5 distribution. Calculated as $\frac{1}{8}(b-a)^2$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_saspoint5.**stdev**()

Returns the *standard deviation* of the Saspoint5 distribution. Calculated as $\sqrt{\frac{1}{8}(b-a)^2}$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_saspoint5.**skewness**()

Returns the *skewness* of the Saspoint5 distribution. Calculated as 0.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_saspoint5.**kurtosis**()

Returns the 'proper' *kurtosis* (normalized fourth moment) of the Saspoint5 distribution. Calculated as $3/2$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_saspoint5.**kurtosis_excess**()

Returns the *kurtosis excess* of the Saspoint5 distribution. Calculated as $-3/2$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_saspoint5.**support_lower_endpoint**()

Returns the *support* of the Saspoint5 distribution as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_saspoint5.**support_upper_endpoint**()

Returns the *support* of the Saspoint5 distribution as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_saspoint5.**range_lower_endpoint**()

Returns the valid *range* of the Saspoint5 distribution as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_saspoint5.**range_upper_endpoint**()

Returns the valid *range* of the Saspoint5 distribution as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

4.13 Elementary discrete (lattice) distributions

4.13.1 Boost: Bernoulli distribution

The following functions return the pmf, cdf, qtf or boost class of the Bernoulli distribution

The Bernoulli distribution is a discrete distribution of the outcome of a single trial with only two results, 0 (failure) or 1 (success), with a probability of success p.

The Bernoulli distribution is the simplest building block on which other discrete distributions of sequences of independent Bernoulli trials can be based.

The Bernoulli is the binomial distribution (k = 1, p) with only one trial.

The domain of the random variable is 0 and 1, and the useful supported range is only 0 or 1.

The support interval for k is $0, 1$, and $0 \leq q \leq 1$.

The Bernoulli distribution is implemented here as a strict discrete distribution. If a generalised version, allowing k to be any real, is required then the binomial distribution with a single trial should be used, for example:

binomial_distribution(1, 0.25)

!!! The following references need to be updated: !!!

See also Wikipedia [1178], MathWorld [823], BoostMath [76] .

math53.**bernoulli_pmf**(p, k)

Returns pmf(x), the value of the probability mass function (*Pmf*) of the Bernoulli distribution. It is calculated using the relation pmf(k) $= 1 - p$ for $k = 0$, else p.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("BernoulliPdf(x, a, b): ", BernoulliPdf(x, a, b))
>>> print ("dist_bernoulli(a, b).pdf(x): ", dist_bernoulli(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

math53.**bernoulli_cdf**(p, k)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the Bernoulli distribution. It is calculated using the relation cdf(k) $= 1 - p$ for $k = 0$, else 1.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("BernoulliCdf(x, a, b): ", BernoulliCdf(x, a, b))
>>> print ("dist_bernoulli(a, b).cdf(x): ", dist_bernoulli(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

math53.**bernoulli_qtf**(p, q)

Returns qtf(q), the value of the quantile function (*Qtf*) of the Bernoulli distribution. It is calculated using the relation qtf(k) $= 0$ for $k \leq (1 - p)$, else 1.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("BernoulliQtf(q, a, b): ", BernoulliQtf(q, a, b))
>>> print ("dist_bernoulli(a, b).qtf(q): ", dist_bernoulli(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

CtxBoost.**dist_bernoulli**(p)

Returns an dist_bernoulli object, which gives access to the functions descibed below:

```
>>> from xlcalcnet import SReal, FReal, ereal, QReal, CReal, OReal
>>> a = 0; b = 1;
>>> Ctx = SReal
>>> dist_bernoulli = Ctx.dist_bernoulli(a, b)
>>> print ("Dist.qtf(q=0.5): ", Dist.qtf(q=0.5))
6.35635234625645256156156145613 56E+00
```

dist_bernoulli.**pmf**(x)

Returns pdf(x), the value of the probability density function of the Bernoulli distribution. See *Ctx.BernoulliPmf* for formulas and examples.

dist_bernoulli.**cdf**(x)

Returns cdf(x), the value of the cumulative distribution function of the Bernoulli distribution. See *Ctx.BernoulliCdf* for formulas and examples.

dist_bernoulli.**qtf**(q)

Returns qtf(q), the value of the quantile function of the Bernoulli distribution. See *Ctx.BernoulliQtf* for formulas and examples.

dist_bernoulli.**sf**(x)

Returns sf(x), the value of the survival function (*Sf*) of the Bernoulli distribution. It is calculated using the relation sf(k) = p for $k = 0$, else 0.

```
>>> # continued from above
>>> print ("Dist.sf(x=0.5): ", Dist.qtf(x=0.5))
6.35635234625645256156156145613 56E+00
```

dist_bernoulli.**isf**(q)

Returns isf(q), the value of the inverse survival function (*Isf*) of the Bernoulli distribution. It is calculated using the relation qtf(k) = 1 for $k \leq (1 - p)$, else 0.

```
>>> # continued from above
>>> print ("Dist.isf(x=0.5): ", Dist.isf(x=0.5))
6.35635234625645256156156145613 56E+00
```

dist_bernoulli.**hf**(x)

Returns hazard(x), the value of the hazard function (*Hf*) of the Bernoulli distribution.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_bernoulli.**chf**(x)

Returns chf(x), the value of the cumulative hazard function (*Chf*) of the Bernoulli distribution.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_bernoulli.**mode**()

Returns the *mode* of the Bernoulli distribution, which is 0 if $(p < 0.5)$ else 1.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_bernoulli.**median**()

Returns the *median* of the Bernoulli distribution. Calculated as *tbd*.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_bernoulli.**mean**()

Returns the *mean* (expected value) of the Bernoulli distribution, which is p.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_bernoulli.**variance**()

Returns the *variance* of the Bernoulli distribution. Calculated as $p(1 - p)$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_bernoulli.**stdev**()

Returns the *standard deviation* of the Bernoulli distribution. Calculated as $\sqrt{p(1 - p)}$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
```

(continues on next page)

(continued from previous page)

```
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_bernoulli.**skewness**()

Returns the *skewness* of the Bernoulli distribution. Calculated as $(1 - 2p)/\sqrt{p(1-p)}$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_bernoulli.**kurtosis**()

Returns the 'proper' *kurtosis* (normalized fourth moment) of the Bernoulli distribution. Calculated as $3+(1-6p(1-p))/(p(1-p))$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_bernoulli.**kurtosis_excess**()

Returns the *kurtosis excess* of the Bernoulli distribution. Calculated as $(1 - 6p(1-p))/(p(1-p))$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_bernoulli.**support_lower_endpoint**()

Returns the *support* of the Bernoulli distribution as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_bernoulli.**support_upper_endpoint**()

Returns the *support* of the Bernoulli distribution as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_bernoulli.**range_lower_endpoint**()

Returns the valid *range* of the Bernoulli distribution as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

dist_bernoulli.**range_upper_endpoint**()

Returns the valid *range* of the Bernoulli distribution as a tuple (left, right).

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", chi_squared(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

4.13.2 Boost: Geometric distribution

The following functions return the pmf, cdf, qtf or boost class of the geometric distribution with parameter $p, 0 \leq p \leq 1$ (p is the probability that any one trial will be successful, it is also known as "success fraction"). The function returns the probability of obtaining exactly k failures from k trials with success fraction p. For this implementation, the set of trials includes zero (unlike another definition where the set of trials starts at one, sometimes named shifted), so the support interval for k is $(0, \infty)$, and $0 \leq q \leq 1$.

See also Wikipedia [1178], MathWorld [823], BoostMath [76] .

|newpage|

math53.**geometric_pmf**(*p*, *k*)

Returns pmf(x), the value of the probability mass function (*Pmf*) of the geometric distribution:

$$\text{pmf}_X(k) = p(1-p)^k = p \cdot \exp\left(k\text{log1p}(-p)\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("GeometricPdf(x, a, b): ", GeometricPdf(x, a, b))
>>> print ("dist_geometric(a, b).pdf(x): ", dist_geometric(a, b).pdf(x))
6.356352346256452561561561561456135 6E+00
```

|newpage|

math53.**geometric_cdf**(*p*, *k*)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the geometric distribution. The cumulative distribution function returns the probability of obtaining k failures or fewer from k trials with success fraction p and success on the last trial.

$$\text{cdf}(x) = 1 - (1-p)^{k+1} = -\text{expm1}\left(\text{log1p}(-p)(k+1)\right).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("GeometricCdf(x, a, b): ", GeometricCdf(x, a, b))
>>> print ("dist_geometric(a, b).cdf(x): ", dist_geometric(a, b).cdf(x))
6.356352346256452561561561561456 1356E+00
```

|newpage|

`math53.`**`geometric_qtf`**(p, q)

Returns qtf(q), the value of the quantile function (*Qtf*) of the geometric distribution. The quantile function returns the greatest number of failures k expected to be observed from k trials with success fraction p, at probability q. Note that the value returned is a real-number, and not an integer. Depending on the use case you may want to take either the floor or ceiling of the real result.

$$\text{qtf}(q) = \frac{\text{log1p}(-q)}{\text{log1p}(-p)} - 1.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("GeometricQtf(q, a, b): ", GeometricQtf(q, a, b))
>>> print ("dist_geometric(a, b).qtf(q): ", dist_geometric(a, b).qtf(q))
6.356352346256452561561561561456 1356E+00
```

|newpage|

`class` `ctx.`**`dist_geometric`**(p)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

The geometric distribution is a (discrete or continuous) probability distribution with parameter $p, 0 \leq p \leq 1$ (p is the probability that any one trial will be successful, it is also known as "success fraction"). The function returns the probability of obtaining exactly k failures from k trials with success fraction p. For this implementation, the set of trials includes zero (unlike another definition where the set of trials starts at one, sometimes named shifted), so the support interval for k is $(0, \infty)$. See also Wikipedia [1178], MathWorld [823], BoostMath [76] , and Witkovský [1487], R (Statistical System) [532].

|newpage|

`dist_geometric.`**`pmf`**(x)

Returns $\text{pmf}_X(x)$, the probability mass function (pmf) of a random variable X, following an geometric distribution:

$$\text{pmf}_X(k) = p(1-p)^k = p \cdot \exp\left(k\text{log1p}(-p)\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pmf: ", geometric(mu, sigma).pmf(x))
6.356352346256452561561561561456 1356E-20
```

|newpage|

dist_geometric.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an geometric distribution:

$$\mathrm{cdf}_X(x) = 1 - (1-p)^{k+1} = -\mathrm{expm1}\left(\mathrm{log1p}(-p)(k+1)\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", geometric(mu, sigma).pmf(x))
6.35635234625645256156156145613 56E-20
```

|newpage|

dist_geometric.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following an geometric distribution:

$$\mathrm{sf}_X(x) = (1-p)^{k+1} = \exp\left(\mathrm{log1p}(-p)(k+1)\right)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", geometric(mu, sigma).pmf(x))
sf: 6.35635234625645256156156145613 56E-20
```

|newpage|

dist_geometric.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following an geometric distribution:

$$\mathrm{qtf}_X(q) = \frac{\mathrm{log1p}(-q)}{\mathrm{log1p}(-p)} - 1$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", geometric(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

|newpage|

dist_geometric.**isf**(q)

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following an geometric distribution:

$$\mathrm{isf}_X(q) = \frac{\log(q)}{\mathrm{log1p}(-p)} - 1$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", geometric(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

|newpage|

dist_geometric.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following an geometric distribution:

$$C_X(t) = ??.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", geometric(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

|newpage|

dist_geometric.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following an geometric distribution:

$$M_X(t) = ??.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", geometric(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

|newpage|

dist_geometric.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an geometric distribution:

$$K_X(t) = ??.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", geometric(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

|newpage|

dist_geometric.**moments**(*k*)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an geometric distribution (Wikipedia). The raw moments are calculated from the central moments.

$$\mu_X(n) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", geometric(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

|newpage|

dist_geometric.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an geometric distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", geometric(mu, sigma).cumulants(k))
6.35635234625645256156156145561356E+00
```

The geometric distribution is used when there are exactly two mutually exclusive outcomes of a Bernoulli trial: these outcomes are labelled "success" and "failure". For Bernoulli trials each with success fraction p, the geometric distribution gives the probability of observing k trials (failures, events, occurrences, or arrivals) before the first success.

The pmf of a variable following a geometric distribution with parameter p is given by

$$f(k;p) = p(1-p)^k$$

The CDF of a variable following a geometric distribution with parameter p is given by

$$F(k;p) = 1 - (1-p)^{k+1}$$

The ICDF of a variable following a geometric distribution with parameter p is given by

$$F^{-1}(x;p) = \frac{\log1\mathrm{p}(-x)}{\log1\mathrm{p}(-p)} - 1$$

4.13.3 Boost: Poisson distribution

The following functions return the pmf, cdf, qtf or boost class of the Poisson distribution with mean mu and the support interval $(0, +\infty)$, and $0 \leq q \leq 1$.

See also Wikipedia [1191], MathWorld [837], BoostMath [84], Ehrhardt [297] (3.9.26).

math53.**poisson_pmf**(*mu*, *x*)

Returns pmf(x), the value of the probability mass function (*Pmf*) of the Poisson distribution:

$$\text{pmf}(x) = \frac{\mu^k}{k!} e^{-\mu}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("PoissonPdf(x, a, b): ", PoissonPdf(x, a, b))
>>> print ("dist_poisson(a, b).pdf(x): ", dist_poisson(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

math53.**poisson_cdf**(*mu*, *x*)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the Poisson distribution:

$$\text{cdf}(x) = e^{-\mu} \sum_{i=0}^{k} \frac{\mu^i}{i!} = Q(1 + k, \mu).$$

Here $Q(\cdot)$ denotes the upper regularized incomplete gamma function (*RealGammaQ*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("PoissonCdf(x, a, b): ", PoissonCdf(x, a, b))
>>> print ("dist_poisson(a, b).cdf(x): ", dist_poisson(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

math53.**poisson_qtf**(*mu*, *q*)

Returns qtf(q), the value of the quantile function (*Qtf*) of the Poisson distribution:

$$\text{qtf}(q) = \text{gammaq_inva}(\mu, p) - 1.$$

Here $\text{gammaq_inva}(\cdot)$ denotes the inverse (on parameter a) of the real upper normalised incomplete gamma function (*RealGammaQInva*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("PoissonQtf(q, a, b): ", PoissonQtf(q, a, b))
>>> print ("dist_poisson(a, b).qtf(q): ", dist_poisson(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class ctx.**dist_poisson**(*lambda1*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The Poisson distribution is a discrete (lattice) probability distribution with mean mu and the support interval $(0, +\infty)$. See also Wikipedia [1191], MathWorld [837], BoostMath [84], and Witkovský [1494], R (Statistical System) [535].

See also: https://docs.scipy.org/doc/scipy/reference/generated/scipy.special.pdtrik.html#scipy.special.pdtrik

dist_poisson.**pmf**(x)

Returns $\mathrm{pmf}_X(x)$, the probability mass function (pmf) of a random variable X, following a Poisson distribution:

$$\mathrm{pmf}_X(x) = \frac{\lambda_1^k}{k!} e^{-\lambda_1}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pmf: ", poisson(mu, sigma).pmf(x))
6.356352346256452561561561456135 6E-20
```

dist_poisson.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Poisson distribution:

$$\mathrm{cdf}_X(x) = e^{-\lambda_1} \sum_{i=0}^{k} \frac{\lambda_1^i}{i!} = Q(1+k, \lambda_1).$$

Here $Q(\cdot)$ denotes the upper regularized incomplete gamma functions.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", poisson(mu, sigma).pmf(x))
6.356352346256452561561561456135 6E-20
```

dist_poisson.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a Poisson distribution:

$$\mathrm{sf}_X(x) = 1 - e^{-\lambda_1} \sum_{i=0}^{k} \frac{\lambda_1^i}{i!} = P(1+k, \lambda_1).$$

Here $P(\cdot)$ denotes the lower regularized incomplete gamma functions.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", poisson(mu, sigma).pmf(x))
sf: 6.356352346256452561561561456135 6E-20
```

dist_poisson.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Poisson distribution.

$$\text{qtf}_X(q) = \text{gamma}_{\text{q}}\text{_inva}(\lambda_1, p) - 1.$$

Here $\text{gamma}_{\text{q}}\text{_inva}(\cdot)$ denotes the inverse (on parameter a) of the real normalised incomplete gamma function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", poisson(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_poisson.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Poisson distribution:

$$\text{isf}_X(q) = \text{gamma}_{\text{p}}\text{_inva}(\lambda_1, q) - 1.$$

Here $\text{gamma}_{\text{p}}\text{_inva}(\cdot)$ denotes the inverse (on parameter a) of the real normalised complementary incomplete gamma function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", poisson(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_poisson.**g_x**(t)

Returns $G_X(t)$, the probability generating function of a random variable X, following a Poisson distribution:

$$G_X(t) = \exp(\lambda(t-1)).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", poisson(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_poisson.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Poisson distribution:

$$C_X(t) = \exp(\lambda(e^{it}-1)).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", poisson(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_poisson.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following a Poisson distribution:

$$M_X(t) = \exp(\lambda(e^t - 1)).$$

$$L_X(t) = \exp(\lambda(e^{-t} - 1)).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", poisson(mu, sigma).c_x(t))
6.356352346256452561561561456135 6E+00
```

dist_poisson.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a Poisson distribution:

$$K_X(t) = \lambda(e^t - 1).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", poisson(mu, sigma).k_x(t, k))
6.356352346256452561561561456135 6E+00
```

dist_poisson.**moments**(*k*)

Returns the first j moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Poisson distribution (Wikipedia). The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", poisson(mu, sigma).moments(k))
6.356352346256452561561561456135 6E+00
```

dist_poisson.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a Poisson distribution:

$$\kappa_r = \lambda, \quad r = 1, 2, \ldots$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", poisson(mu, sigma).cumulants(k))
6.356352346256452561561561456135 6E+00
```

Approximations

ctx.**poisson_ecf**(*x*, *f*, *rho*, *omega*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Edgeworth approximation to the pdf, cdf and sf.

ctx.**poisson_ecf_inv**(*x*, *f*, *rho*, *omega*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Cornish-Fisher approximation to the qtf and isf.

ctx.**poisson_spa**(*x*, *n*, *results='c'*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

Calculates the Luggannini-Rice saddlepoint approximation of the pdf, cdf and sf.

The solution $\hat{s}(x)$ of the saddlepoint equation $K_X^{(1)}(\hat{s}(x)) = x$, of a random variable X, following a Poisson distribution is given by:

$$\hat{s}(x) = \log(k/\lambda).$$

ctx.**poisson_spa_inv**(*x*, *n*, *results='qtf'*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

4.13.4 Boost: Binomial distribution

The following functions return the pmf, cdf, qtf or boost class of the binomial distribution with number of trials $n \geq 0$ and success probability $0 \leq p \leq 1$, and $0 \leq q \leq 1$.

See also Wikipedia [1175], MathWorld [818], BoostMath [71], Ehrhardt [297] (3.9.3).

math53.**binomial_pmf**(*n*, *p*, *k*)

Returns pmf(x), the value of the probability density function (*Pmf*) of the binomial distribution:

$$\text{pmf}(x) = \binom{n}{k} p^k (1-p)^{n-k} = f_{\text{Beta}}(k+1, n-k+1, p)/(n+1).$$

Here $f_{\text{Beta}}(\cdot)$ denotes the PDF of the central beta distribution.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("BinomialPdf(x, a, b): ", BinomialPdf(x, a, b))
>>> print ("dist_binomial(a, b).pdf(x): ", dist_binomial(a, b).pdf(x))
6.356352346256452561561561561456 1356E+00
```

math53.**binomial_cdf**(*n*, *p*, *k*)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the binomial distribution:

$$\text{cdf}(x) = \sum_{j=0}^{k} \text{pmf}_X(j) = \text{ibetac}(k+1, n-k, p).$$

Here ibetac$(\cdot)$ denotes the real normalised complementary incomplete beta function (*RealIBetac*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("BinomialCdf(x, a, b): ", BinomialCdf(x, a, b))
>>> print ("dist_binomial(a, b).cdf(x): ", dist_binomial(a, b).cdf(x))
6.356352346256452561561561561456 1356E+00
```

math53.**binomial_qtf**(*n*, *p*, *q*)

Returns qtf(q), the value of the quantile function (*Qtf*) of the binomial distribution:

There is no known closed form for qtf(q): it is computed with Newton iterations where the starting values are from the corresponding Boost functions.

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("BinomialQtf(q, a, b): ", BinomialQtf(q, a, b))
>>> print ("dist_binomial(a, b).qtf(q): ", dist_binomial(a, b).qtf(q))
6.356352346256452561561561561456 1356E+00
```

class ctx.**dist_binomial**(n, p)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The binomial distribution is a discrete (lattice) probability distribution with number of trials $n \geq 0$ and success probability $0 \leq p \leq 1$. See also Wikipedia [1175], MathWorld [818], BoostMath [71], Witkovský [1484], R (Statistical System) [531].

A special case is the Bernoulli distribution, see See also Wikipedia [1174], MathWorld [817], and BoostMath [70].

See also: https://docs.scipy.org/doc/scipy/reference/generated/scipy.special.bdtrin.html#scipy.special.bdtrin

dist_binomial.**pmf**(x)

Returns $\mathrm{pmf}_X(x)$, the probability mass function (pmf) of a random variable X, following an binomial distribution:

$$\mathrm{pmf}_X(x) = \binom{n}{k} p^k (1-p)^{n-k} = f_{\mathrm{Beta}}(k+1, n-k+1, p)/(n+1).$$

and $f_{\mathrm{Beta}}(\cdot)$ and $F_{\mathrm{Beta}}(\cdot)$ denote the PDF and CDF, respectively, of the central beta distribution.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pmf: ", binomial(mu, sigma).pmf(x))
6.35635234625645256156156145613 56E-20
```

dist_binomial.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an binomial distribution:

$$\mathrm{cdf}_X(x) = \sum_{j=0}^{k} \mathrm{pmf}_X(j) = F_{\mathrm{Beta}}(1-p; n-k, k+1).$$

and $f_{\mathrm{Beta}}(\cdot)$ and $F_{\mathrm{Beta}}(\cdot)$ denote the PDF and CDF, respectively, of the central beta distribution.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", binomial(mu, sigma).pmf(x))
6.35635234625645256156156145613 56E-20
```

dist_binomial.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following an binomial distribution:

$$\mathrm{sf}_X(x) = 1 - \mathrm{cdf}_X(x).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", binomial(mu, sigma).pmf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_binomial.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following an binomial distribution. There is no closed form for the qtf: It is computed with Newton iterations where the starting values are from Boost.

$$\text{qtf}_X(q) = tbd.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", binomial(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_binomial.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following an binomial distribution:

$$\text{isf}_X(q) = \text{qtf}_X(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", binomial(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_binomial.**g_x**(t)

Returns $G_X(t)$, the probability generating function of a random variable X, following an binomial distribution:

$$G_X(t) = (Pt + Q)^n.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", binomial(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_binomial.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an binomial distribution:

$$C_X(t) = \left(Pe^{it} + Q\right)^n.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", binomial(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_binomial.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following an binomial distribution:

$$M_X(t) = \left(Pe^t + Q\right)^n.$$

$$L_X(t) = \left(Pe^{-t} + Q\right)^n.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", binomial(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

dist_binomial.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an binomial distribution:

$$K_X(t) = K_X(t) = n \log\left(Pe^t + Q\right).$$

$K_X(t)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(t), j = 1 \ldots k$, of a random variable X, following a binomial distribution, are defined as

$$K_X(t) = n \log\left(p \cdot e^t + 1 - p\right),$$

$$K_X^{(1)}(t) = \frac{n \cdot p \cdot e^x}{p(e^x - 1) + 1},$$

$$K_X^{(2)}(t) = -\frac{n(p-1)p \cdot e^x}{(p(e^x - 1) + 1)^2},$$

$$K_X^{(3)}(t) = \frac{n(p-1)p \cdot e^x (p \cdot e^x + p - 1)}{(p(e^x - 1) + 1)^3},$$

and for $j \geq 4$ the derivatives are calculated by numerically differentiating $K_X^{(3)}(t)$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", binomial(mu, sigma).k_x(t, k))
6.356352346256452561561561561456 1356E+00
```

dist_binomial.**moments**(*k*)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an binomial distribution (Wikipedia). The raw moments are calculated from the central moments.

$$\mu_X(r) = nPQ \sum_{i=0}^{r-2} \binom{r-1}{i} \mu_i - P \sum_{i=0}^{r-2} \binom{r-1}{i} \mu_{i+1}, \quad r > 2; \quad \mu_1 = nP, \quad \mu_2 = nPQ.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", binomial(mu, sigma).moments(k))
6.356352346256452561561561561456 1356E+00
```

`dist_binomial.`**`cumulants`**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an binomial distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", binomial(mu, sigma).cumulants(k))
6.3563523462564525615615615614561356E+00
```

Approximations

`ctx.`**`hypergeo_ft`**(*x*, *n*, *results='cdf'*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the pdf, cdf and sf from the characteristic function (see *pmf_from_cf_lattice()* and *cdf_from_cf_lattice()*).

`ctx.`**`binomial_ft`**(*x*, *n*, *results='cdf'*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the pdf, cdf and sf from the characteristic function (see *pmf_from_cf_lattice()* and *cdf_from_cf_lattice()*).

`ctx.`**`binomial_ecf`**(*k*, *n*, *p*, *results='cdf'*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Edgeworth approximation to the pdf, cdf and sf, support $k \in \{0, \cdots n\}$.

`ctx.`**`binomial_ecf_inv`**(*q*, *n*, *p*, *results='qtf'*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Cornish-Fisher approximation to the qtf and isf.

`ctx.`**`binomial_spa`**(*k*, *n*, *p*, *results='cdf'*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Luggannini-Rice saddlepoint approximation of the pdf, cdf and sf.

The saddlepoint is given by

$$\hat{s}(x) = \log\left(\frac{kQ}{(n-k)P}\right).$$

`ctx.`**`binomial_spa_inv`**(*q*, *n*, *p*, *results='qtf'*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

4.13.5 Boost: Negative binomial distribution

The following functions return the pmf, cdf, qtf or boost class of the negative binomial distribution with target for number of successful trials $r > 0$ and success probability $0 \leq p \leq 1$, and $0 \leq q \leq 1$.

See also Wikipedia [1190], MathWorld [834], BoostMath [83], Ehrhardt [297] (3.9.23).

`math53.negbinomial_pmf`(r, p, k)

Returns $\text{pmf}(x)$, the value of the probability mass function (*Pmf*) of the negative binomial distribution:

$$\text{pmf}(x) = \frac{\Gamma(k+r)}{k!\Gamma(r)} p^r (1-p)^k.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("NegbinomPdf(x, a, b): ", NegbinomPdf(x, a, b))
>>> print ("dist_negbinomial(a, b).pdf(x): ", dist_negbinomial(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.negbinomial_cdf`(r, p, k)

where `Ctx` is `Math53` or `CtxBoost`.

Returns $\text{cdf}(x)$, the value of the cumulative distribution function (*Cdf*) of the negative binomial distribution:

$$\text{cdf}(x) = \sum_{j=0}^{k} \text{pmf}_X(j) = \text{ibeta}(r, k+1, p).$$

Here $\text{ibeta}(\cdot)$ denotes the real normalised incomplete beta function (*RealIBeta*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("NegbinomCdf(x, a, b): ", NegbinomCdf(x, a, b))
>>> print ("dist_negbinomial(a, b).cdf(x): ", dist_negbinomial(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.negbinomial_qtf`(r, p, q)

Returns $\text{qtf}(q)$, the value of the quantile function (*Qtf*) of the negative binomial distribution:

$$\text{qtf}(q) = \text{ibeta_invb}(r, p, q) - 1.$$

Here $\text{ibeta_invb}(\cdot)$ denotes the inverse (on parameter b) of the real normalised incomplete beta function (*RealIBetaInvb*).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("NegbinomQtf(q, a, b): ", NegbinomQtf(q, a, b))
>>> print ("dist_negbinomial(a, b).qtf(q): ", dist_negbinomial(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class ctx.**dist_negbinom**(r, p)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The negative binomial distribution is a discrete (lattice) probability distribution with target for number of successful trials $r > 0$ and success probability $0 \leq p \leq 1$. See also Wikipedia [1190], MathWorld [834], BoostMath [83] , and Witkovský [1491], R (Statistical System) [534].

See also: https://docs.scipy.org/doc/scipy/reference/generated/scipy.special.nbdtrin.html#scipy.special.nbdtrin

dist_negbinom.**pmf**(x)

Returns $\mathrm{pmf}_X(x)$, the probability mass function (pmf) of a random variable X, following an negative binomial distribution:

$$\mathrm{pmf}_X(x) = \frac{\Gamma(n+k)}{K!\Gamma(n)} P^n (1-P)^k.$$

and $f_{\mathrm{Beta}}(\cdot)$ and $F_{\mathrm{Beta}}(\cdot)$ denote the PDF and CDF, respectively, of the central beta distribution. The following recursions are used for the PMF:

$$\Pr(X = k+1|n) = \frac{(n+k)(1-P)}{(k+1)} \Pr(X = k|n)$$

$$\Pr(X = k-1|n) = \frac{k}{(n-k+1)(1-P)} \Pr(X = k|n)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pmf: ", negative_binomial(mu, sigma).pmf(x))
6.35635234625645256156156145613 56E-20
```

dist_negbinom.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an negative binomial distribution:

$$\mathrm{cdf}_X(x) = \sum_{j=0}^{k} \mathrm{pmf}_X(j) = F_{\mathrm{Beta}}(1-p; r, k+1).$$

and $f_{\mathrm{Beta}}(\cdot)$ and $F_{\mathrm{Beta}}(\cdot)$ denote the PDF and CDF, respectively, of the central beta distribution.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", negative_binomial(mu, sigma).pmf(x))
6.35635234625645256156156145613 56E-20
```

dist_negbinom.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following an negative binomial distribution:

$$\mathrm{sf}_X(x) = 1 - \mathrm{cdf}_X(x).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", negative_binomial(mu, sigma).pmf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_negbinom.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following an negative binomial distribution:

$$\mathrm{qtf}_X(q) = a - b \ln\left((1-y)/y\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", negative_binomial(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

dist_negbinom.**isf**(q)

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following an negative binomial distribution:

$$\mathrm{isf}_X(q) = \mathrm{qtf}_X(1-q) = \mathrm{cdf}_X^{-1}(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", negative_binomial(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

dist_negbinom.**g_x**(t)

Returns $G_X(t)$, the probability generating function of a random variable X, following an negative binomial distribution:

$$G_X(t) = \left(\frac{1}{P} - \frac{1-P}{P}t\right)^{-n}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", negative_binomial(mu, sigma).c_x(t))
6.3563523462564525615615615614561356E+00
```

dist_negbinom.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an negative binomial distribution:

$$C_X(t) = \left(\frac{1}{P} - \frac{1-P}{P}e^{it}\right)^{-n}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", negative_binomial(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

dist_negbinom.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following an negative binomial distribution:

$$M_X(t) = \left(\frac{1}{P} - \frac{1-P}{P}e^t\right)^{-n}.$$

$$L_X(t) = \left(\frac{1}{P} - \frac{1-P}{P}e^t\right)^{-n}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", negative_binomial(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

dist_negbinom.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an negative binomial distribution:

$$K_X(t) = -n \log\left(\frac{1}{P} - \frac{1-P}{P}e^t\right).$$

$K_X(t)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(t), j = 1 \ldots k$, of a random variable X, following a negative binomial distribution, are defined as

$$K_X(t) = r \log\left(\frac{1-p}{1-p\cdot e^t}\right), \quad \text{for } t < -\log(p)$$

$$K_X^{(1)}(t) = \frac{p\cdot r\cdot e^x}{1-p\cdot e^x},$$

$$K_X^{(2)}(t) = \frac{p\cdot r\cdot e^x}{(1-p\cdot e^x)^2},$$

$$K_X^{(3)}(t) = \frac{p\cdot r\cdot e^x(p\cdot e^x+1)}{(1-p\cdot e^x)^3},$$

and for $j \geq 4$ the derivatives are calculated by numerically differentiating $K_X^{(3)}(t)$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", negative_binomial(mu, sigma).k_x(t, k))
6.356352346256452561561561561456 1356E+00
```

dist_negbinom.**moments**(k)

Returns the first j central moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an negative binomial distribution (Wikipedia). The raw moments are calculated from the central moments.

$$\mu_X(r) = \mu_2 \sum_{i=0}^{r-2} \binom{r-1}{i} \mu_i - \frac{1-P}{P} \sum_{i=0}^{r-2} \binom{r-1}{i} \mu_{i+1}, \quad r > 2; \quad \mu_1 = n\frac{1-P}{P}, \quad \mu_2 = \frac{\mu_1}{P}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", negative_binomial(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_negbinom.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an negative binomial distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", negative_binomial(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

Approximations

ctx.**negbinom_ecf**(k, r, p, *results='cdf'*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Edgeworth approximation to the pdf, cdf and sf

ctx.**negbinom_ecf_inv**(q, r, p, *results='qtf'*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Cornish-Fisher approximation to the qtf and isf.

ctx.**negbinom_spa**(k, r, p, *results='c'*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Luggannini-Rice saddlepoint approximation of the pdf, cdf and sf.

The saddlepoint is given by:

$$\hat{s}(x) = \log\left(\frac{k(1-P)}{(n-k)P}\right).$$

ctx.**negbinom_spa_inv**(q, r, p, *results='qtf'*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

4.13.6 Boost: Classical hypergeometric distribution

The following functions return pmf, cdf, qtf or boost class of the hypergeometric distribution, with k successes (random draws for which the object drawn has a specified feature) in $n \in \{0, 1, 2, \ldots, N\}$ draws, without replacement, from a finite population of size $N \in \{0, 1, 2, \ldots\}$‘ that contains exactly $K \in \{0, 1, 2, \ldots, N\}$ objects with that feature, wherein each draw is either a success or a failure, and the support interval $(\max(0, n + K - N), \min(K, n))$, and $0 \leq q \leq 1$.

See also Wikipedia [1181], MathWorld [826], BoostMath [78], Team [533], Berkopec [31], Johnson *et al.* [389] page 251, Ehrhardt [297] (3.9.11).

`math53.`**`hypergeometric_pmf`**(r, n, N, k)

Returns pmf(k), the value of the probability mass function (*Pmf*) of the hypergeometric distribution.

$$\text{pmf}_X(k) = \frac{\binom{K}{k}\binom{N-K}{n-k}}{\binom{N}{n}}.$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("HypergeoPdf(x, a, b): ", HypergeoPdf(x, a, b))
>>> print ("dist_hypergeometric(a, b).pdf(x): ", dist_hypergeometric(a, b).pdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`hypergeometric_cdf`**(r, n, N, k)

Returns cdf(x), the value of the cumulative distribution function (*Cdf*) of the hypergeometric distribution:

$$\text{cdf}_X(k) = \sum_{j=\max(0,n+K-N)}^{k} \text{pmf}_X(j).$$

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; x = 0.6;
>>> print ("HypergeoCdf(x, a, b): ", HypergeoCdf(x, a, b))
>>> print ("dist_hypergeometric(a, b).cdf(x): ", dist_hypergeometric(a, b).cdf(x))
6.35635234625645256156156145613 56E+00
```

`math53.`**`hypergeometric_qtf`**(r, n, N, q)

Returns qtf(q), the value of the quantile function (*Qtf*) of the hypergeometric distribution:

There is no known closed exact form for qtf(q) or isf(q).

The following example shows both forms of the syntax:

```
>>> from xlcalcnet import *
>>> a = 0; b = 1; t = 0.3; q = 0.6;
>>> print ("HypergeoQtf(q, a, b): ", HypergeoQtf(q, a, b))
>>> print ("dist_hypergeometric(a, b).qtf(q): ", dist_hypergeometric(a, b).qtf(q))
6.35635234625645256156156145613 56E+00
```

class ctx.**dist_hypergeometric**(n, K, N)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The hypergeometric distribution is a discrete (lattice) probability distribution with k successes (random draws for which the object drawn has a specified feature) in $n \in \{0, 1, 2, \ldots, N\}$ draws, without replacement, from a finite population of size $N \in \{0, 1, 2, \ldots\}$‘ that contains exactly $K \in \{0, 1, 2, \ldots, N\}$ objects with that feature, wherein each draw is either a success or a failure, and the support interval $(\max(0, n+K-N), \min(K, n))$. See also Wikipedia [1181], MathWorld [826], BoostMath [78], R (Statistical System) [533], Berkopec [31], Johnson *et al.* [389] page 251.

dist_hypergeometric.**pmf**(x)

Returns $\text{pmf}_X(x)$, the probability mass function (pmf) of a random variable X, following an hypergeometric distribution:

$$\text{pmf}_X(x) = \binom{K}{k}\binom{N-K}{n-k}\Big/\binom{N}{n}.$$

The following recursions are used for the PMF:

$$f(k+1) = \frac{(n_1-k)(n-k)}{(k+1)(n_2-n+k+1}f(k)$$

$$f(k-1) = \frac{k(n_2-n+k)}{(n_1-k+1)(n-k+1}f(k)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pmf: ", hypergeometric(mu, sigma).pmf(x))
6.3563523462564525615615615614561356E-20
```

dist_hypergeometric.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following an hypergeometric distribution:

$$\text{cdf}_X(k) = \sum_{j=\max(0,n+K-N)}^{k} \text{pmf}_X(j) = 1 - \text{pmf}_X(k+1) \times {}_3F_2(1, k+1-K, k+1-n; k+2, N+k+2-K-n; 1),$$

where ${}_3F_2(\cdot)$ is a generalized hypergeometric function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", hypergeometric(mu, sigma).pmf(x))
6.3563523462564525615615615614561356E-20
```

dist_hypergeometric.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following an hypergeometric distribution:

$$\text{sf}_X(k) = \sum_{j=k+1}^{\min(K,n)} \text{pmf}_X(j) = \text{pmf}_X(k+1) \times {}_3F_2(1, k+1-K, k+1-n; k+2, N+k+2-K-n; 1),$$

where ${}_3F_2(\cdot)$ is a generalized hypergeometric function.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", hypergeometric(mu, sigma).pmf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_hypergeometric.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following an hypergeometric distribution.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", hypergeometric(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_hypergeometric.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following an hypergeometric distribution:

$$\text{isf}_X(q) = \text{qtf}_X(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", hypergeometric(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_hypergeometric.**g_x**(t)

Returns $G_X(t)$, the probability generating function of a random variable X, following an hypergeometric distribution:

$$G_X(t) = {}_2F_1(-n, -K; N-K-n+1; t)\binom{N-K}{n} \Big/ \binom{N}{n}.$$

where ${}_2F_1(\cdot)$ is the Gauss hypergeometric function (see *hyp2f1()*.)

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", hypergeometric(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_hypergeometric.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following an hypergeometric distribution:

$$C_X(t) = {}_2F_1(-n, -K; N-K-n+1; e^{it})\binom{N-K}{n} \Big/ \binom{N}{n}.$$

where ${}_2F_1(\cdot)$ is the Gauss hypergeometric function (see *hyp2f1()*.)

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", hypergeometric(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

`dist_hypergeometric.m_x(t)`

Returns $M_X(t)$, the moment generating function of a random variable X, following an hypergeometric distribution:

$$M_X(t) = {}_2F_1(-n, -K; N-K-n+1; e^t)\binom{N-K}{n}\Big/\binom{N}{n}.$$

$$L_X(t) = {}_2F_1(-n, -K; N-K-n+1; e^{-t})\binom{N-K}{n}\Big/\binom{N}{n}.$$

where ${}_2F_1(\cdot)$ is the Gauss hypergeometric function (see *hyp2f1()*.)

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", hypergeometric(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

`dist_hypergeometric.k_x(t, k=0)`

Returns $K_X(t)$, the cumulant generating function of a random variable X, following an hypergeometric distribution:

$$K_X(t) = \log\left[({}_2F_1(-n, -K; N-K-n+1; e^t)\binom{N-K}{n}\Big/\binom{N}{n}\right].$$

where ${}_2F_1(\cdot)$ is the Gauss hypergeometric function (see *hyp2f1()*.)

$K_X(t)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(t), j = 1 \ldots k$, of a random variable X, following a hypergeometric distribution, are defined as

$$K_X(t) = \log\left(T \cdot {}_2F_1(a, b; c; e^t)\right), \quad \text{where } a = -n, b = -K, c = N-K-n+1, T = \binom{N-K}{n}\Big/\binom{N}{n}.$$

$$K_X^{(1)}(t) = \frac{a \cdot b \cdot e^x \cdot G_1(x)}{c \cdot G_0(x)}, \quad \text{where } G_i(x) = {}_2F_1(a+i, b+i; c+i; e^t),$$

$$K_X^{(2)}(t) = -\frac{a^2 \cdot b^2 \cdot e^{2x} \cdot (G_1(x))^2}{c^2 \cdot (G_0(x))^2} + \frac{a \cdot b \cdot e^x \cdot G_1(x)}{c \cdot G_0(x)} + \frac{a(a+1) \cdot b(b+1) \cdot e^{2x} \cdot G_2(x)}{c(c+1) \cdot G_0(x)},$$

$$K_X^{(3)}(t) = \frac{2a^3 \cdot b^3 \cdot e^{3x} \cdot (G_1(x))^3}{c^3 \cdot (G_0(x))^3} - \frac{3a^2 \cdot b^2 \cdot e^{2x} \cdot (G_1(x))^2}{c^2 \cdot (G_0(x))^2} - \frac{3a^2(a+1) \cdot b^2(b+1) \cdot e^{3x} \cdot G_2(x) \cdot G_1(x)}{c(c+1) \cdot G_0(x)}$$
$$+ \frac{a \cdot b \cdot e^x \cdot G_1(x)}{c \cdot G_0(x)} + \frac{3a(a+1) \cdot b(b+1) \cdot e^{2x} \cdot G_2(x)}{c(c+1) \cdot G_0(x)} + \frac{a(a+1)(a+2) \cdot b(b+1)(b+2) \cdot e^{3x} \cdot G_3(x)}{c(c+1)(c+2) \cdot G_0(x)}$$

and for $j \geq 4$ the derivatives are calculated by numerically differentiating $K_X^{(3)}(t)$. We also have

$$\frac{\mathrm{d}}{\mathrm{d}z}\left({}_2F_1(a, b, c; z)\right) = \frac{ab}{c} \cdot {}_2F_1(a+1, b+1, c+1; z), \quad \text{and}$$

$$z(1-z) \cdot \frac{\mathrm{d}^2}{\mathrm{d}z^2}\left({}_2F_1(a, b, c; z)\right) + (c - (a+b+1)z) \cdot \frac{\mathrm{d}}{\mathrm{d}z}\left({}_2F_1(a, b, c; z)\right) - ab \cdot {}_2F_1(a, b, c; z) = 0.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", hypergeometric(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_hypergeometric.**moments**(k)

Returns the first j raw moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following an hypergeometric distribution (Wikipedia).

$$\mu'_X(r) = \sum_{j=1}^{j_{\max}} S_{r,j} T_j, \quad \text{where } j_{\max} = \min(r, n, M, N),$$

$$S_{r,1} = S_{r,r} = 1, \quad S_{r+1,j} = jS_{r,j} + S_{r,j-1}, \quad \text{and}$$

$$T_1 = nM/N, \quad T_{j+1} = T_j(n-j)(M-j)/(N-j).$$

$$\mu'_{[r]} = \frac{n!K!(K+(N-K)-r)!}{(n-r)!(K-r)!(K+(N-K))!}$$

$$\mu'_{[r]} = \frac{n!K!(N-r)!}{(n-r)!(K-r)!N!}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", hypergeometric(mu, sigma).moments(k))
6.35635234625645256156156145614356E+00
```

dist_hypergeometric.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following an hypergeometric distribution. The cumulants are calculated from the moments.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", hypergeometric(mu, sigma).cumulants(k))
6.35635234625645256156156145614356E+00
```

Approximations

ctx.**hypergeo_ecf**(k, n, K, N, *results='cdf'*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Edgeworth approximation to the pdf, cdf and sf.

ctx.**hypergeo_ecf_inv**(q, n, K, N, *results='qtf'*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Cornish-Fisher approximation to the qtf and isf.

ctx.**hypergeo_spa**(k, n, K, N, *results='cdf'*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Luggannini-Rice saddlepoint approximation of the pdf, cdf and sf.

where ctx is ipm, dec, mpm, or gmp.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

4.14 Discrete (lattice) distributions related to (stratified) rank tests

4.14.1 Wilcoxon signed rank T distribution, continuous data

class ctx.**dist_wilcoxon**(N)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of Wilcoxon's signed rank test is a discrete (lattice) probability distribution with sample size $N > 2$ and the support interval $(0, N(N+1))$. See also Wikipedia [1197], R (Statistical System) [530], Fellingham and Stoker [300], vandeWiel [791], Bennett [29] and Zimmermann [1503].

We consider N continuously distributed random variables $D_i, i = 1 \ldots N$, with common pdf h_0. In a sample $(d_1, \ldots, d_N)$ of size N let r_i be the rank of d_i in the ordered sample.

The test criterion of Wilcoxon's Signed Rank is $T_N = \sum_{i=1}^{N} S(d_i) r_i$, where $S(d_i) = 1$ for $x > 0$ and $S(d_i) = 0$ for $x < 0$. T_N can assume values between 0 and $\frac{1}{2}N(N+1)$ in steps of 1.

dist_wilcoxon.**pmf**(x)

Returns $\mathrm{pmf}_X(k)$, the probability mass function (pmf) of a random variable X, following the distribution of Wilcoxon's signed rank test, with sample size $N > 2$ and the support interval $(0, N(N+1)/2)$.

$$\mathrm{pmf}_X(x) = \sum_{j=x}^{N(N+1)/2} (-1)^{x+j} \binom{j}{x} \frac{\mu'_{[j]}}{j!},$$

where $\mu'_{[j]}$ is the j^{th} factorial moment.

The factorial moments are calculated from the cumulants (see *factorial_moments_from_cumulants()*).

The pmf can also be calculated from the characteristic function $C_X(t)$:

$$\mathrm{pmf}(x) = \frac{1}{\pi} \int_0^{\pi} \Re\left(e^{-itx} C_X(t)\right) \mathrm{d}t,$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pmf: ", wilcoxon_continuous(mu, sigma).pmf(x))
6.35635234625645256156156145561356E-20
```

dist_wilcoxon.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Wilcoxon signed rank T distribution.

$$\mathrm{cdf}_X(x) = \sum_{j=x}^{N(N+1)/2} (-1)^{x+j} \binom{j-1}{x-1} \frac{\mu'_{[j]}}{j!},$$

where $\mu'_{[j]}$ is the j^{th} factorial moment.

The cdf can also be calculated from the characteristic function $C_X(t)$:

$$\mathrm{cdf}(x) = \frac{1}{\pi} \int_0^{\pi} \Re\left(C_X(t) \sum_{z=0}^{x} e^{-itz}\right) \mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", wilcoxon_continuous(mu, sigma).pmf(x))
6.35635234625645256156156145613 56E-20
```

dist_wilcoxon.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a Wilcoxon signed rank T distribution:

$$\mathrm{sf}_X(x) = 1 - \sum_{j=x}^{N(N+1)/2} (-1)^{x+j} \binom{j-1}{x-1} \frac{\mu'_{[j]}}{j!},$$

where $\mu'_{[j]}$ is the j^{th} factorial moment.

The cdf can also be calculated from the characteristic function $C_X(t)$:

$$\mathrm{sf}(x) = 1 - \mathrm{cdf}(x) = \frac{1}{\pi} \int_0^{\pi} \Re \left(C_X(t) \sum_{z=x+1}^{N(N+1)/2} e^{-itz} \right) \mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", wilcoxon_continuous(mu, sigma).pmf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_wilcoxon.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Wilcoxon signed rank T distribution. There is no closed form for the qtf: It is computed using the Brent algorithm with starting values from a Cornish-Fisher or Jensen approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", wilcoxon_continuous(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_wilcoxon.**isf**(q)

Returns $\mathrm{isf}_X(x)$, the inverse survival function (isf) of a random variable X, following a Wilcoxon signed rank T distribution. There is no closed form for the isf: It is computed using the Brent algorithm with starting values from a Cornish-Fisher or Jensen approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", wilcoxon_continuous(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_wilcoxon.**g_x**(*t*)

Returns $G_X(x)$, the probability generating function of a random variable X, following a Wilcoxon signed rank T distribution:

$$G_X(x) = \frac{1}{2^N} \prod_{h=1}^{N} (1 + x^h)$$

See also: v.d.Wiel, p. 17, equ. 2.15

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", wilcoxon_continuous(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

dist_wilcoxon.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Wilcoxon signed rank T distribution:

$$C_X(t) = \exp\left(\tfrac{1}{4}N(N+1)it\right) \prod_{h=1}^{N} \cosh\left(\tfrac{h}{2}it\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", wilcoxon_continuous(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

dist_wilcoxon.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following a Wilcoxon signed rank T distribution:

$$M_X(t) = \exp\left(\tfrac{1}{4}N(N+1)t\right) \prod_{h=1}^{N} \cosh\left(\tfrac{h}{2}t\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", wilcoxon_continuous(mu, sigma).c_x(t))
6.356352346256452561561561561456 1356E+00
```

dist_wilcoxon.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a Wilcoxon signed rank T distribution:

$$K_X(t) = \tfrac{1}{4}N(N+1)t + \sum_{h=1}^{N} \log\left(\cosh\left(\tfrac{h}{2}t\right)\right).$$

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a Wilcoxon signed rank T distribution:

$$K_X(t) = \tfrac{1}{2}n\log(4p(1-p)) + \tfrac{1}{4}n(n+1)t + \sum_{h=1}^{n} \log\left(\cosh\left(\tfrac{1}{2}(\log(p/(1-p)) + h\cdot t)\right)\right).$$

$K_X(t)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(t), j = 1\ldots k$, of a random variable X, following a Wilcoxon signed rank T distribution, are defined as:

$$K_X(t) = \tfrac{1}{4}n(n+1)t + \sum_{h=1}^{n} \log\left(\cosh\left(\tfrac{h}{2}t\right)\right),$$

$$K_X^{(1)}(t) = \sum_{h=1}^{n} \frac{h}{2}\left(1 - \frac{2}{\exp(h\cdot s)+1}\right),$$

See also `Bennett1` in `DistCiornishArb.vb`.

$$K_X^{(j)}(t) = \sum_{h=1}^{n} h^j \cdot \sum_{k=1}^{j} c(j-2,k)\left(\exp(h\cdot s)+1\right)^{-k}, \quad j \geq 2.$$

where the coefficients $c(i,j)$ are calculated recursively, with $c(0,1) = c(0,2) = c(i,1) = 1$, and

$$c(i,j) = (j-1)\cdot c(i-1,j-1) + j\cdot c(i-1,j), \quad j \geq 2.$$

The saddlepoint s is determined numerically using Newton iterations, with a starting value of $s = 0$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", wilcoxon_continuous(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_wilcoxon.**moments**(*k*)

Returns the first j moments, $\mu_j, j = 1\ldots k$, of a random variable X, following a Wilcoxon signed rank T distribution. The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", wilcoxon_continuous(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_wilcoxon.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1\ldots k$, of a random variable X, following a Wilcoxon signed rank T distribution. The cumulants of W are given by:

$$\kappa_{2j} = \frac{2^{2j}(2^{2j}-1)B_{2j}}{2j}\sum_{i=1}^{N} r_i^{2j} = \frac{2^{2j}(2^{2j}-1)B_{2j}}{2j}\frac{B_{2j+1}(N+1) - B_{2j+1}}{2j+1},$$

where $\kappa_1 = N(N+1)/4$), $\kappa_{2j+1} = 0$ for $j \geq 1$, and B_{2j} and $B_{2j}(x)$ are the Bernoulli numbers and polynomials, respectively, of degree $2j$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", wilcoxon_continuous(mu, sigma).cumulants(k))
6.35635234625645256156156145614561356E+00
```

Approximations

`ctx.`**`wilcoxon_ft`**(*x*, *n*, *results='cdf'*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the pdf, cdf and sf from the characteristic function (see *pmf_from_cf_lattice()* and *cdf_from_cf_lattice()*).

`ctx.`**`wilcoxon_ecf`**(*x*, *f*, *rho*, *omega*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Edgeworth approximation to the pdf, cdf and sf.

`ctx.`**`wilcoxon_ecf_inv`**(*q*, *f*, *rho*, *omega*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Cornish-Fisher approximation to the qtf and isf.

`ctx.`**`wilcoxon_spa`**(*x*, *n*, *results='c'*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the Luggannini-Rice saddlepoint approximation of the pdf, cdf and sf.

The saddlepoint s is determined numerically using Newton iterations, with a starting value of $s = 0$.

`ctx.`**`wilcoxon_spa_inv`**(*q*, *n*, *results='qtf'*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

4.14.2 Noncentral Wilcoxon signed rank T distribution, Bennett alternatives

class ctx.**dist_bennett**(N)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of Wilcoxon's signed rank test is a discrete (lattice) probability distribution with sample size $N > 2$ and the support interval $(0, N(N+1))$. See also Wikipedia [1197], R (Statistical System) [530], Fellingham and Stoker [300], vandeWiel [791], Bennett [29] and Zimmermann [1503].

We consider N continuously distributed random variables $D_i, i = 1 \ldots N$, with common pdf h_0. In a sample $(d_1, \ldots, d_N)$ of size N let r_i be the rank of d_i in the ordered sample.

The test criterion of Wilcoxon's Signed Rank is $T_N = \sum_{i=1}^{N} S(d_i) r_i$, where $S(d_i) = 1$ for $x > 0$ and $S(d_i) = 0$ for $x < 0$. T_N can assume values between 0 and $\frac{1}{2}N(N+1)$ in steps of 1.

dist_bennett.**pmf**(x)

Returns $\mathrm{pmf}_X(x)$, the probability mass function (pmf) of a random variable X, following a Wilcoxon signed rank T distribution. The null distribution can be calculated as follows: Let $p_N(w)$ denote the probability $\Pr[W_N = w]$ in a sample of size N. Then the following recurrence relation holds (Zimmermann_1985_dependent) :

$$p_N(w) = \tfrac{1}{2}\left(p_{N-1}(w) + p_{N-1}(w-N)\right).$$

$$\mathrm{pmf}_X(x) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pmf: ", wilcoxon_continuous(mu, sigma).pmf(x))
6.35635234625645256156156145613 56E-20
```

dist_bennett.**cdf**(x)

Returns $\mathrm{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Wilcoxon signed rank T distribution.

$$\mathrm{cdf}_X(x) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", wilcoxon_continuous(mu, sigma).pmf(x))
6.35635234625645256156156145613 56E-20
```

dist_bennett.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a Wilcoxon signed rank T distribution:

$$\mathrm{sf}_X(x) = 1 - \mathrm{cdf}_X(x)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", wilcoxon_continuous(mu, sigma).pmf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_bennett.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Wilcoxon signed rank T distribution. There is no closed form for the qtf: It is computed with Newton iterations where the starting values are from Boost.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", wilcoxon_continuous(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145614356E+00
```

dist_bennett.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Wilcoxon signed rank T distribution:

$$\text{isf}_X(q) = \text{qtf}_X(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", wilcoxon_continuous(mu, sigma).isf(q))
6.35635234625645256156156145614356E+00
```

dist_bennett.**g_x**(t)

Returns $G_X(t)$, the probability generating function of a random variable X, following a Wilcoxon signed rank T distribution:

$$G_X(t) = \prod_{h=1}^{n} \left(pt^h + (1-p)\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", wilcoxon_continuous(mu, sigma).c_x(t))
6.35635234625645256156156145614356E+00
```

dist_bennett.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Wilcoxon signed rank T distribution:

$$C_X(t) = \exp\left(\tfrac{1}{4}n(n+1)it\right) \prod_{h=1}^{n} \cosh\left(\tfrac{h}{2}it\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", wilcoxon_continuous(mu, sigma).c_x(t))
6.35635234625645256156156145614356E+00
```

dist_bennett.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a Wilcoxon signed rank T distribution:

$$M_X(t) = (4p(1-p))^{\frac{1}{2}n} \exp\left(\tfrac{1}{4}n(n+1)t\right) \prod_{h=1}^{n} \cosh\left(\tfrac{1}{2}(\log(p/(1-p)) + h \cdot t)\right), \quad a =$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", wilcoxon_continuous(mu, sigma).c_x(t))
6.356352346256452561561561456135 6E+00
```

dist_bennett.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a Wilcoxon signed rank T distribution:

$$K_X(t) = \tfrac{1}{2}n\log(4p(1-p)) + \tfrac{1}{4}n(n+1)t + \sum_{h=1}^{n}\log\left(\cosh\left(\tfrac{1}{2}(\log(p/(1-p)) + h\cdot t)\right)\right).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", wilcoxon_continuous(mu, sigma).k_x(t, k))
6.356352346256452561561561456135 6E+00
```

dist_bennett.**moments**(*k*)

Returns the first j moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Wilcoxon signed rank T distribution (Wikipedia). The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", wilcoxon_continuous(mu, sigma).moments(k))
6.356352346256452561561561456135 6E+00
```

dist_bennett.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a Wilcoxon signed rank T distribution. The cumulants of W are given by (Fellingham_1964) :

Central case:

$$\kappa_{2j}(W_N) = \frac{2^{2j}(2^{2j}-1)B_{2j}}{2j}\sum_{i=1}^{N} r_i^{2j} = \frac{2^{2j}(2^{2j}-1)B_{2j}}{2j}\frac{B_{2j+1}(N+1) - B_{2j+1}}{2j+1}, \quad \text{and}$$

$$\kappa_{2j+1}(W_N) = 0, \quad \text{for } j \geq 0.$$

Noncentral case:

$$\kappa_1 = \tfrac{1}{4}n(n+1)(1+\tanh(0.5a)) = \tfrac{1}{2}n(n+1)p$$

$$\kappa_2 = \tfrac{1}{6}n(n+1)(2n+1)p(1-p)$$

$$\kappa_3 = \tfrac{1}{4}n^2(n+1)^2pq(q-p)$$

$$\kappa_4 = \tfrac{1}{30}n(n+1)(2n+1)(3n^2+3n-1)pq(1-6pq)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", wilcoxon_continuous(mu, sigma).cumulants(k))
6.356352346256452561561561456135 6E+00
```

4.14.3 Mann-Whitney U distribution, continuous data

class ctx.**dist_mann_whitney_u**(*N1*, *N2*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of Mann-Whitney's U is a discrete (lattice) probability distribution with sample sizes $N_1 \geq 1$ and $N_2 \geq 1$ and the support interval $(0, N_1 \cdot N_2))$. See also Wikipedia [1187], R (Statistical System) [529], Murakami and Kamakura [420], vandeWiel [791], Robillard [483] and Zimmermann [1504].

Let $x_1, \ldots, x_{N_1}$ and $y1, \ldots, y_{N_2}$ be two sets of measurements, which we denote by X and Y. The test criterion U of the Mann-Whitney test is then

$$U = \sum_{j=1}^{N_1} \sum_{k=1}^{N_2} \operatorname{sgn}(x_k - y_k)$$

dist_mann_whitney_u.**pmf**(x)

Returns $\operatorname{pmf}_X(x)$, the probability mass function (pmf) of a random variable X, following a Mann-Whitney U distribution.

$$\operatorname{pmf}_X(x) = \sum_{j=x}^{N_1 \cdot N_2} (-1)^{x+j} \binom{j}{x} \frac{\mu'_{[j]}}{j!},$$

where $\mu'_{[j]}$ is the j^{th} factorial moment.

The factorial moments are calculated from the cumulants (see *factorial_moments_from_cumulants()*).

The pmf can also be calculated from the characteristic function $C_X(t)$:

$$\operatorname{pmf}(x) = \frac{1}{\pi} \int_0^{\pi} \Re\left(e^{-itx} C_X(t)\right) \mathrm{d}t,$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pmf: ", mann_whitney_u_continuous(mu, sigma).pmf(x))
6.35635234625645256156156145613 56E-20
```

dist_mann_whitney_u.**cdf**(x)

Returns $\operatorname{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Mann-Whitney U distribution.

$$\operatorname{cdf}_X(x) = \sum_{j=x}^{N_1 \cdot N_2} (-1)^{x+j} \binom{j-1}{x-1} \frac{\mu'_{[j]}}{j!},$$

where $\mu'_{[j]}$ is the j^{th} factorial moment.

The cdf can also be calculated from the characteristic function $C_X(t)$:

$$\operatorname{cdf}(x) = \frac{1}{\pi} \int_0^{\pi} \Re\left(C_X(t) \sum_{z=0}^{x} e^{-itz}\right) \mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", mann_whitney_u_continuous(mu, sigma).pmf(x))
6.35635234625645256156156145613 56E-20
```

dist_mann_whitney_u.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a Mann-Whitney U distribution:

$$\mathrm{sf}_X(x) = 1 - \sum_{j=x}^{N_1 \cdot N_2} (-1)^{x+j} \binom{j-1}{x-1} \frac{\mu'_{[j]}}{j!},$$

where $\mu'_{[j]}$ is the j^{th} factorial moment.

The cdf can also be calculated from the characteristic function $C_X(t)$:

$$\mathrm{sf}(x) = 1 - \mathrm{cdf}(x) = \frac{1}{\pi} \int_0^{\pi} \Re \left(C_X(t) \sum_{z=x+1}^{N_1 \cdot N_2} e^{-itz} \right) \mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", mann_whitney_u_continuous(mu, sigma).pmf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_mann_whitney_u.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Mann-Whitney U distribution. There is no closed form for the qtf: It is computed using the Brent algorithm with starting values from a Cornish-Fisher or Jensen approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", mann_whitney_u_continuous(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_mann_whitney_u.**isf**(q)

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Mann-Whitney U distribution. There is no closed form for the isf: It is computed using the Brent algorithm with starting values from a Cornish-Fisher or Jensen approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", mann_whitney_u_continuous(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_mann_whitney_u.**g_x**(t)

Returns $G_X(t)$, the probability generating function of a random variable X, following a Mann-Whitney U distribution:

$$G_X(t) = \frac{1}{\binom{N_1+N_2}{N_1}} \frac{\prod_{r=N_1+1}^{N_1+N_2} (1-x^r)}{\prod_{r=1}^{N_2} (1-x^r)}.$$

See also: v.d.Wiel, p. 14, equ. 2.5

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mann_whitney_u_continuous(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_mann_whitney_u.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Mann-Whitney U distribution:

$$C_X(t) = \prod_{r=1}^{N_2} \frac{r}{N_2 + r} \frac{1 - \exp((N_2 + r)it)}{1 - \exp(itr)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mann_whitney_u_continuous(mu, sigma).c_x(t))
6.35635234625645256156156145613356E+00
```

dist_mann_whitney_u.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following a Mann-Whitney U distribution:

$$M_X(t) = \prod_{r=1}^{N_2} \frac{r}{N_2 + r} \frac{1 - \exp((N_2 + r)t)}{1 - \exp(tr)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", mann_whitney_u_continuous(mu, sigma).c_x(t))
6.35635234625645256156156145613356E+00
```

dist_mann_whitney_u.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a Mann-Whitney U distribution:

$$K_X(t) = \sum_{r=1}^{N_2} \log\left(\frac{r}{N_2 + r} \frac{1 - \exp((N_2 + r)t)}{1 - \exp(tr)}\right).$$

$K_X(t)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(t), j = 1 \ldots k$, of a random variable X, following a Mann-Whitney U distribution, are defined as

$$K_X(t) = \sum_{r=1}^{m} \log\left(\frac{r}{n + r} \frac{1 - \exp((n + r)t)}{1 - \exp(t \cdot r)}\right),$$

$$K_X^{(1)}(s) = \sum_{r=1}^{m} \left(\frac{n + r}{1 - \exp((n + r)s)} - \frac{n(\exp(r \cdot s) + n + r)}{1 - \exp(r \cdot s)}\right),$$

See also `Murakami1_new` in `DistCiornishArb.vb`.

$$K_X^{(j)}(s) = (-1)^j \sum_{r=1}^{m} \sum_{i=0}^{1} (-1)^i \cdot t_i^j \cdot \sum_{k=1}^{j} c(j-2, k) \cdot z_i^j, \quad j \geq 2, \quad \text{where}$$

$$z_i = \frac{1}{1 - \exp(t_i \cdot s)}, \quad t_i = \begin{cases} n + r, & i = 0, \\ r & i = 1, \end{cases}$$

and the coefficients $c(i, j)$ are calculated recursively, with $c(0, 1) = c(0, 2) = c(i, 1) = 1$, and

$$c(i, j) = (j - 1) \cdot c(i - 1, j - 1) + j \cdot c(i - 1, j), \quad j \geq 2.$$

See also `Murakami2_deriv2` in `DistCiornishArb.vb`.

The saddlepoint s is determined numerically using Newton iterations, with a starting value of $s = 0.1$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", mann_whitney_u_continuous(mu, sigma).k_x(t, k))
6.3563523462564525615615615614561356E+00
```

`dist_mann_whitney_u.`**moments**`(`k`)`

Returns the first j moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Mann-Whitney U distribution (Wikipedia). The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mann_whitney_u_continuous(mu, sigma).moments(k))
6.3563523462564525615615615614561356E+00
```

`dist_mann_whitney_u.`**cumulants**`(`k`)`

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a Mann-Whitney U distribution. The cumulants of U are given by (Robillard1972):

$$\begin{aligned}\kappa_{2j} &= \frac{B_{2j}}{2j}\left[\sum_{s=N_1+1}^{N_1+N_2} s^{2j} - \sum_{s=1}^{N_2} s^{2j}\right] \\ &= \frac{B_{2j}}{2j(2j+1)}\left[B_{2j+1}(N_2+N_1+1) + B_{2j+1} - B_{2j+1}(N_1+1) - B_{2j+1}(N_2+1)\right]\end{aligned}$$

and $\kappa_{2j+1} = 0$, $j \geq 1$, and B_{2j} and $B_{2j}(x)$ are the Bernoulli numbers and polynomials, respectively, of degree $2j$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mann_whitney_u_continuous(mu, sigma).cumulants(k))
6.3563523462564525615615615614561356E+00
```

Approximations

`ctx.`**mannwhitney_ft**`(`*x*, *n*, *results='cdf'*`)`

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the pdf, cdf and sf from the characteristic function (see *pmf_from_cf_lattice()* and *cdf_from_cf_lattice()*).

`ctx.`**mannwhitney_ecf**`(`*x*, *f*, *rho*, *omega*`)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Edgeworth approximation to the pdf, cdf and sf.

`ctx.`**mannwhitney_ecf_inv**`(`*q*, *f*, *rho*, *omega*`)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Cornish-Fisher approximation to the qtf and isf.

ctx.**mannwhitney_spa**(*x*, *m*, *n*, *results='c'*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

Calculates the Luggannini-Rice saddlepoint approximation of the pdf, cdf and sf.

The saddlepoint s is determined numerically using Newton iterations, with a starting value of $s = 0.1$.

ctx.**mannwhitney_spa_inv**(*q*, *m*, *n*, *results='qtf'*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

4.14.4 Noncentral Mann-Whitney U distribution, Lehmann alternatives

class ctx.**dist_mann_whitney_u_lehmann**(m, n)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of Mann-Whitney's U is a discrete (lattice) probability distribution with sample sizes $m \geq 1$ and $n \geq 1$ and the support interval $(0, nm))$. See also Wikipedia [1187], R (Statistical System) [529], Murakami and Kamakura [420], Robillard [483], vandeWiel [791] and Zimmermann [1504].

Let $x1, \ldots, x_m$ and $y1, \ldots, y_n$ be two sets of measurements, which we denote by X and Y. The test criterion U of the Mann-Whitney test is then

$$U = \sum_{i=1}^{m} \sum_{j=1}^{n} \operatorname{sgn}(x_i - y_j)$$

dist_mann_whitney_u_lehmann.**pmf**(x)

Returns $\operatorname{pmf}_X(x)$, the probability mass function (pmf) of a random variable X, following a Mann-Whitney U distribution under Lehmann alternatives.

$$\operatorname{pmf}_X(x) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pmf: ", mann_whitney_u_continuous(mu, sigma).pmf(x))
6.3563523462564525615615615614561356E-20
```

dist_mann_whitney_u_lehmann.**cdf**(x)

Returns $\operatorname{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Mann-Whitney U distribution under Lehmann alternatives.

$$\operatorname{cdf}_X(x) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", mann_whitney_u_continuous(mu, sigma).pmf(x))
6.3563523462564525615615615614561356E-20
```

dist_mann_whitney_u_lehmann.**sf**(x)

Returns $\operatorname{sf}_X(x)$, the survival function (sf) of a random variable X, following a Mann-Whitney U distribution under Lehmann alternatives:

$$\operatorname{sf}_X(x) = 1 - \operatorname{cdf}_X(x)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", mann_whitney_u_continuous(mu, sigma).pmf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_mann_whitney_u_lehmann.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Mann-Whitney U distribution under Lehmann alternatives. There is no closed form for the qtf: It is computed with Newton iterations where the starting values are from Boost.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", mann_whitney_u_continuous(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145614356E+00
```

dist_mann_whitney_u_lehmann.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Mann-Whitney U distribution under Lehmann alternatives:

$$\text{isf}_X(q) = \text{qtf}_X(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", mann_whitney_u_continuous(mu, sigma).isf(q))
6.35635234625645256156156145614356E+00
```

dist_mann_whitney_u_normal.**g_x**(t)

Returns $G_X(t)$, the probability generating function of a random variable X, following a Mann-Whitney U distribution under Lehmann alternatives:

$$G_X(t) = ??$$

dist_mann_whitney_u_lehmann.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Mann-Whitney U distribution under Lehmann alternatives:

$$C_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mann_whitney_u_continuous(mu, sigma).c_x(t))
6.35635234625645256156156145614356E+00
```

dist_mann_whitney_u_lehmann.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a Mann-Whitney U distribution under Lehmann alternatives:

$$M_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", mann_whitney_u_continuous(mu, sigma).c_x(t))
6.356352346256452561561561456135 6E+00
```

dist_mann_whitney_u_lehmann.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a Mann-Whitney U distribution under Lehmann alternatives:

$$K_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", mann_whitney_u_continuous(mu, sigma).k_x(t, k))
6.356352346256452561561561456135 6E+00
```

dist_mann_whitney_u_lehmann.**moments**(*k*)

Returns the first j moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Mann-Whitney U distribution under Lehmann alternatives (Wikipedia). The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mann_whitney_u_continuous(mu, sigma).moments(k))
6.356352346256452561561561456135 6E+00
```

dist_mann_whitney_u_lehmann.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a Mann-Whitney U distribution under Lehmann alternatives.

kappa_{j} = ??

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mann_whitney_u_continuous(mu, sigma).cumulants(k))
6.356352346256452561561561456135 6E+00
```

4.14.5 Noncentral Mann-Whitney U distribution, Milton alternatives

class ctx.**dist_mann_whitney_u_milton**(m, n)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of Mann-Whitney's U is a discrete (lattice) probability distribution with sample sizes $m \geq 1$ and $n \geq 1$ and the support interval $(0, nm))$. See also Wikipedia [1187], R (Statistical System) [529], Murakami and Kamakura [420], Robillard [483], vandeWiel [791] and Zimmermann [1504].

Let $x1, \ldots, x_m$ and $y1, \ldots, y_n$ be two sets of measurements, which we denote by X and Y. The test criterion U of the Mann-Whitney test is then

$$U = \sum_{i=1}^{m} \sum_{j=1}^{n} \operatorname{sgn}(x_i - y_j)$$

dist_mann_whitney_u_milton.**pmf**(x)

Returns $\operatorname{pmf}_X(x)$, the probability mass function (pmf) of a random variable X, following a Mann-Whitney U distribution under Milton alternatives.

$$\operatorname{pmf}_X(x) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pmf: ", mann_whitney_u_continuous(mu, sigma).pmf(x))
6.35635234625645256156156145613 56E-20
```

dist_mann_whitney_u_milton.**cdf**(x)

Returns $\operatorname{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Mann-Whitney U distribution under Milton alternatives.

$$\operatorname{cdf}_X(x) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", mann_whitney_u_continuous(mu, sigma).pmf(x))
6.35635234625645256156156145613 56E-20
```

dist_mann_whitney_u_milton.**sf**(x)

Returns $\operatorname{sf}_X(x)$, the survival function (sf) of a random variable X, following a Mann-Whitney U distribution under Milton alternatives:

$$\operatorname{sf}_X(x) = 1 - \operatorname{cdf}_X(x)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", mann_whitney_u_continuous(mu, sigma).pmf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_mann_whitney_u_milton.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Mann-Whitney U distribution under Milton alternatives. There is no closed form for the qtf: It is computed with Newton iterations where the starting values are from Boost.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", mann_whitney_u_continuous(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145614561356E+00
```

dist_mann_whitney_u_milton.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Mann-Whitney U distribution under Milton alternatives:

$$\text{isf}_X(q) = \text{qtf}_X(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", mann_whitney_u_continuous(mu, sigma).isf(q))
6.35635234625645256156156145614561356E+00
```

dist_mann_whitney_u_milton.**g_x**(t)

Returns $G_X(t)$, the probability generating function of a random variable X, following a Mann-Whitney U distribution under Milton alternatives:

$$G_X(t) = ??$$

dist_mann_whitney_u_milton.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Mann-Whitney U distribution under Milton alternatives:

$$C_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", mann_whitney_u_continuous(mu, sigma).c_x(t))
6.35635234625645256156156145614561356E+00
```

dist_mann_whitney_u_milton.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a Mann-Whitney U distribution under Milton alternatives:

$$M_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", mann_whitney_u_continuous(mu, sigma).c_x(t))
6.356352346256452561561561456135 6E+00
```

dist_mann_whitney_u_milton.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a Mann-Whitney U distribution under Milton alternatives:

$$K_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", mann_whitney_u_continuous(mu, sigma).k_x(t, k))
6.356352346256452561561561456135 6E+00
```

dist_mann_whitney_u_milton.**moments**(*k*)

Returns the first j moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Mann-Whitney U distribution under Milton alternatives (Wikipedia). The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mann_whitney_u_continuous(mu, sigma).moments(k))
6.356352346256452561561561456135 6E+00
```

dist_mann_whitney_u_milton.**cumulants**(*k*)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a Mann-Whitney U distribution under Milton alternatives.

kappa_{j} = ??

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", mann_whitney_u_continuous(mu, sigma).cumulants(k))
6.356352346256452561561561456135 6E+00
```

4.14.6 Kendall's tau distribution, continuous data

class ctx.**dist_kendall_tau**(*N*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of $K_N = \frac{1}{4}N(N-1)(1-\tau)$ is a discrete (lattice) probability distribution with sample size $N \geq 2$ and the support interval $(0, N(N-1)/2)$. See also Wikipedia [1184], Noether [425], vandeWiel [791], Robillard [483].

Let $(X_1, Y_1), ..., (X_N, Y_N)$ be a sample of N pairs of observations. The Kendall rank correlation coefficient τ is defined as

$$\tau = 1 - \frac{2K_N}{N(N-1)/2}$$

where K_N is the number of inversions: the number of pairs $\{(X_i, Y_i), (X_j, Y_j)\}$ such that $X_i < X_j$ and $Y_i > Y_j$ for $i < j$, where $i = 1, \ldots n-1$ and $j = 2, \ldots, n$. K_N can assume values between 0 and $N(N-1)/2$, whereas τ can assume values between -1 and $+1$.

dist_kendall_tau.**pmf**(*x*)

Returns $\text{pmf}_X(x)$, the probability mass function (pmf) of a random variable X, following the distribution of Kendall's K_N.

$$\text{pmf}_X(x) = \sum_{j=x}^{N(N-1)/2} (-1)^{x+j} \binom{j}{x} \frac{\mu'_{[j]}}{j!},$$

where $\mu'_{[j]}$ is the j^{th} factorial moment.

The factorial moments are calculated from the cumulants (see *factorial_moments_from_cumulants()*).

The pmf can also be calculated from the characteristic function $C_X(t)$:

$$\text{pmf}(x) = \frac{1}{\pi} \int_0^{\pi} \Re\left(e^{-itx} C_X(t)\right) \mathrm{d}t,$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pmf: ", kendall_tau_continuous(mu, sigma).pmf(x))
6.3563523462564525615615615614561356E-20
```

dist_kendall_tau.**cdf**(*x*)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following the distribution of Kendall's K_N:

$$\text{cdf}_X(x) = \sum_{j=x}^{N(N-1)/2} (-1)^{x+j} \binom{j-1}{x-1} \frac{\mu'_{[j]}}{j!},$$

where $\mu'_{[j]}$ is the j^{th} factorial moment.

The cdf can also be calculated from the characteristic function $C_X(t)$:

$$\text{cdf}(x) = \frac{1}{\pi} \int_0^{\pi} \Re\left(C_X(t) \sum_{z=0}^{x} e^{-itz}\right) \mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", kendall_tau_continuous(mu, sigma).pmf(x))
6.35635234625645256156156145613 56E-20
```

dist_kendall_tau.**sf**(x)

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following the distribution of Kendall's K_N:

$$\mathrm{sf}_X(x) = 1 - \sum_{j=x}^{N(N-1)/2} (-1)^{x+j} \binom{j-1}{x-1} \frac{\mu'_{[j]}}{j!},$$

where $\mu'_{[j]}$ is the j^{th} factorial moment.

The cdf can also be calculated from the characteristic function $C_X(t)$:

$$\mathrm{sf}(x) = 1 - \mathrm{cdf}(x) = \frac{1}{\pi} \int_0^{\pi} \Re \left(C_X(t) \sum_{z=x+1}^{N(N-1)/2} e^{-itz} \right) \mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", kendall_tau_continuous(mu, sigma).pmf(x))
sf: 6.35635234625645256156156145613 56E-20
```

dist_kendall_tau.**qtf**(q)

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following the distribution of Kendall's K_N. There is no closed form for the qtf: It is computed using the Brent algorithm with starting values from a Cornish-Fisher or Jensen approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", kendall_tau_continuous(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_kendall_tau.**isf**(q)

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following the distribution of Kendall's K_N. There is no closed form for the isf: It is computed using the Brent algorithm with starting values from a Cornish-Fisher or Jensen approximation

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", kendall_tau_continuous(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_kendall_tau.**g_x**(*t*)

Returns $G_X(t)$, the probability generating function of a random variable X, following the distribution of Kendall's K_N:

$$G_X(t) = \frac{1}{N!} \prod_{k=1}^{N} \frac{(t^k - 1)}{(t - 1)}.$$

See also: v.d.Wiel, p. 16, equ. 2.1

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", kendall_tau_continuous(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_kendall_tau.**c_x**(*t*)

Returns $C_X(t)$, the characteristic function of a random variable X, following the distribution of Kendall's K_N:

$$C_X(t) = \frac{1}{N!} \prod_{k=1}^{N} \frac{\exp(it \cdot k) - 1}{\exp(it) - 1}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", kendall_tau_continuous(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_kendall_tau.**m_x**(*t*)

Returns $M_X(t)$, the moment generating function of a random variable X, following the distribution of Kendall's K_N:

$$M_X(t) = \frac{1}{N!} \prod_{k=1}^{N} \frac{\exp(t \cdot k) - 1}{\exp(t) - 1}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", kendall_tau_continuous(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_kendall_tau.**k_x**(*t*, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following the distribution of Kendall's K_N:

$$K_X(t) = -\log(N!) + \sum_{k=1}^{N} \log\left(\frac{\exp(t \cdot k) - 1}{\exp(t) - 1}\right).$$

$K_X(t)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(t), j = 1 \ldots k$, of a random variable X, following a Kendall tau distribution, are defined as

$$K_X(t) = \sum_{j=2}^{k} \log\left(\frac{1}{N_j + 1} \frac{1 - \exp((N_j + 1)t)}{1 - \exp(t)}\right).$$

$$K_X^{(1)}(s) = \sum_{r=1}^{m} \left(\frac{n+r}{1-\exp((n+r)s)} - \frac{n(\exp(r\cdot s)+n+r)}{1-\exp(r\cdot s)} \right),$$

$$K_X^{(j)}(s) = (-1)^j \sum_{r=1}^{m} \sum_{i=0}^{1} (-1)^i \cdot t_i^j \cdot \sum_{k=1}^{j} c(j-2,k) \cdot z_i^j, \quad j \geq 2, \quad \text{where}$$

$$z_i = \frac{1}{1-\exp(t_i \cdot s)}, \quad t_i = \begin{cases} n+r, & i=0, \\ r & i=1, \end{cases}$$

and the coefficients $c(i,j)$ are calculated recursively, with $c(0,1) = c(0,2) = c(i,1) = 1$, and

$$c(i,j) = (j-1)\cdot c(i-1,j-1) + j \cdot c(i-1,j), \quad j \geq 2.$$

The saddlepoint s is determined numerically using Newton iterations, with a starting value of $s = 0.1$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", kendall_tau_continuous(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

`dist_kendall_tau.`**`moments`**`(`*`k`*`)`

Returns the first j moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following the distribution of Kendall's K_N (Wikipedia). The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", kendall_tau_continuous(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

`dist_kendall_tau.`**`cumulants`**`(`*`k`*`)`

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following the distribution of Kendall's K_N. The cumulants of T_N are given by

$$\kappa_{2j}(T_N) = \frac{B_{2j}}{2j} \sum_{s=1}^{N} s^{2j} = \frac{B_{2j}}{2j} \left[\frac{B_{2j+1}(N+1) - B_{2j+1}}{2j+1} - N \right], \quad \text{and}$$

$$\kappa_{2j+1}(W_N) = 0, \quad \text{for } j \geq 1.$$

In particular, $\kappa_1(T_N) = N(N-1)/4$, and $\kappa_2(T_N) = N(N-1)(2N+5)/72$, and B_{2j} and $B_{2j}(x)$ are the Bernoulli numbers and polynomials, respectively, of degree $2j$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", kendall_tau_continuous(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

Approximations

`ctx.`**`kendall_ft`**`(`*`x`*`, `*`n`*`, `*`results='cdf'`*`)`

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the pdf, cdf and sf from the characteristic function (see *pmf_from_cf_lattice()* and *cdf_from_cf_lattice()*).

ctx.**kendall_tau_ecf**(*x*, *f*, *rho*, *omega*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Edgeworth approximation to the pdf.

ctx.**kendall_tau_ecf_inv**(*q*, *f*, *rho*, *omega*)

where ctx is ipm, dec, mpm, or gmp.

Calculates the Cornish-Fisher approximation to the qtf and isf.

ctx.**kendall_tau_spa**(*x*, *n*, *results='c'*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

Calculates the Lugannini-Rice saddlepoint approximation of the pdf, cdf and sf.

The saddlepoint s is determined numerically using Newton iterations, with a starting value of $s = 0.1$.

ctx.**kendall_tau_spa_inv**(*x*, *n*, *results='qtf'*)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

4.14.7 Jonckheere-Terpsta T distribution, continuous data

class ctx.**dist_jterpsta_s**(k, n)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of Jonckheere-Terpsta's T is a discrete (lattice) probability distribution with k samples of size $n_1 \geq 1, \ldots, n_k \geq 1$ and the support interval $[0, M]$). See also Wikipedia [1183], Murakami and Kamakura [420], vandeWiel [791], Robillard [483]. and Skillings [502].

Consider k independent groups X_i of sizes $n_i, i = 1 \ldots k$, and define $N_i = \sum_{j=1}^{i-1} n_j$ and $M = \sum_{i=2}^{k} n_i N_i$. The Jonckheere-Terpsta statistic is defined as

$$J_T = \sum_{i<j}^{c} U_{ij} = \sum_{i=1}^{c-1} \sum_{j=i+1}^{c} U_{ij}$$

where U_{ij} is Mann-Whitney's U calculated for groups X_i and X_j.

Let S_i denote the combined samples $X_1, ..., X_i$, and let T_i be the Mann-Whitney T statistic calculated for groups S_{i-1} and X_i, $i = 2...k$. Then $T = \sum_{i=2}^{k} T_i$ is related to J_T by $J_T = 2T - M$.

dist_jterpsta_s.**pmf**(x)

Returns $\text{pmf}_X(x)$, the probability mass function (pmf) of a random variable X, following a Jonckheere-Terpsta S distribution.

$$\text{pmf}_X(x) = \sum_{j=x}^{M} (-1)^{x+j} \binom{j}{x} \frac{\mu'_{[j]}}{j!},$$

where $\mu'_{[j]}$ is the j^{th} factorial moment.

The factorial moments are calculated from the cumulants (see *factorial_moments_from_cumulants()*).

The pmf can also be calculated from the characteristic function $C_X(t)$:

$$\text{pmf}(x) = \frac{1}{\pi} \int_0^{\pi} \Re \left(e^{-itx} C_X(t) \right) \mathrm{d}t,$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pmf: ", jonckheere_terpsta_s_continuous(mu, sigma).pmf(x))
6.3563523462564525615615615614561356E-20
```

dist_jterpsta_s.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Jonckheere-Terpsta S distribution.

$$\text{cdf}_X(x) = \sum_{j=x}^{M} (-1)^{x+j} \binom{j-1}{x-1} \frac{\mu'_{[j]}}{j!},$$

where $\mu'_{[j]}$ is the j^{th} factorial moment.

The cdf can also be calculated from the characteristic function $C_X(t)$:

$$\text{cdf}(x) = \frac{1}{\pi} \int_0^{\pi} \Re \left(C_X(t) \sum_{z=0}^{x} e^{-itz} \right) \mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", jonckheere_terpsta_s_continuous(mu, sigma).pmf(x))
6.3563523462564525615615615614561356E-20
```

`dist_jterpsta_s.sf(`x`)`

Returns $\mathrm{sf}_X(x)$, the survival function (sf) of a random variable X, following a Jonckheere-Terpsta S distribution:

$$\mathrm{sf}_X(x) = 1 - \sum_{j=x}^{M} (-1)^{x+j} \binom{j-1}{x-1} \frac{\mu'_{[j]}}{j!},$$

where $\mu'_{[j]}$ is the j^{th} factorial moment.

The cdf can also be calculated from the characteristic function $C_X(t)$:

$$\mathrm{sf}(x) = 1 - \mathrm{cdf}(x) = \frac{1}{\pi} \int_0^{\pi} \Re \left(C_X(t) \sum_{z=x+1}^{M} e^{-itz} \right) \mathrm{d}t.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", jonckheere_terpsta_s_continuous(mu, sigma).pmf(x))
sf: 6.3563523462564525615615615614561356E-20
```

`dist_jterpsta_s.qtf(`q`)`

Returns $\mathrm{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Jonckheere-Terpsta S distribution. There is no closed form for the qtf: It is computed using the Brent algorithm with starting values from a Cornish-Fisher or Jensen approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", jonckheere_terpsta_s_continuous(mu, sigma).qtf(q))
qtf: 6.3563523462564525615615615614561356E+00
```

`dist_jterpsta_s.isf(`q`)`

Returns $\mathrm{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Jonckheere-Terpsta S distribution. There is no closed form for the isf: It is computed using the Brent algorithm with starting values from a Cornish-Fisher or Jensen approximation.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", jonckheere_terpsta_s_continuous(mu, sigma).isf(q))
6.3563523462564525615615615614561356E+00
```

`dist_jterpsta_s.g_x(`t`)`

Returns $G_X(t)$, the characteristic function of a random variable X, following a Jonckheere-Terpsta S distribution:

$$G_X(t) = \prod_{i=2}^{k} \frac{1}{\binom{n_i+N_i}{n_i}} \frac{\prod_{l=N_i+1}^{n_i+N_i}(1-x^l)}{\prod_{l=1}^{n_i}(1-x^l)}.$$

See also: v.d.Wiel, p. 15, equ. 2.9

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", jonckheere_terpsta_s_continuous(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

`dist_jterpsta_s.c_x(t)`

Returns $C_X(t)$, the characteristic function of a random variable X, following a Jonckheere-Terpsta S distribution:

$$C_X(t) = \prod_{j=2}^{k} \prod_{r=1}^{n_j} \frac{r}{N_j + r} \frac{1 - \exp((N_j + r)it)}{1 - \exp(itr)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", jonckheere_terpsta_s_continuous(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

`dist_jterpsta_s.m_x(t)`

Returns $M_X(t)$, the moment generating function of a random variable X, following a Jonckheere-Terpsta S distribution:

$$M_X(t) = \prod_{j=2}^{k} \prod_{r=1}^{n_j} \frac{r}{N_j + r} \frac{1 - \exp((N_j + r)t)}{1 - \exp(tr)}.$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", jonckheere_terpsta_s_continuous(mu, sigma).c_x(t))
6.356352346256452561561561561456135 6E+00
```

`dist_jterpsta_s.k_x(t, k=0)`

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a Jonckheere-Terpsta S distribution:

$$K_X(t) = \sum_{j=2}^{k} \sum_{r=1}^{n_j} \log\left(\frac{r}{N_j + r} \frac{1 - \exp((N_j + r)t)}{1 - \exp(tr)} \right).$$

$K_X(t)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(t), j = 1 \ldots k$, of a random variable X, following a Jonckheere-Terpsta S distribution, are defined as

$$K_X(t) = \sum_{j=2}^{k} \sum_{r=1}^{n_j} \log\left(\frac{r}{N_j + r} \frac{1 - \exp((N_j + r)t)}{1 - \exp(tr)} \right).$$

$$K_X^{(1)}(s) = \sum_{r=1}^{m} \left(\frac{n + r}{1 - \exp((n + r)s)} - \frac{n(\exp(r \cdot s) + n + r)}{1 - \exp(r \cdot s)} \right),$$

$$K_X^{(j)}(s) = (-1)^j \sum_{r=1}^{m} \sum_{i=0}^{1} (-1)^i \cdot t_i^j \cdot \sum_{k=1}^{j} c(j-2, k) \cdot z_i^j, \quad j \geq 2, \quad \text{where}$$

$$z_i = \frac{1}{1-\exp(t_i \cdot s)}, \quad t_i = \begin{cases} n+r, & i=0, \\ r & i=1, \end{cases}$$

and the coefficients $c(i,j)$ are calculated recursively, with $c(0,1) = c(0,2) = c(i,1) = 1$, and

$$c(i,j) = (j-1) \cdot c(i-1, j-1) + j \cdot c(i-1, j), \quad j \geq 2.$$

The saddlepoint s is determined numerically using Newton iterations, with a starting value of $s = 0.1$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", jonckheere_terpsta_s_continuous(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

`dist_jterpsta_s.`**`moments`**`(`*k*`)`

Returns the first j moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Jonckheere-Terpsta S distribution (Wikipedia). The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", jonckheere_terpsta_s_continuous(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

`dist_jterpsta_s.`**`cumulants`**`(`*k*`)`

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a Jonckheere-Terpsta S distribution. The cumulants of J_N are given by (Robillard1972):

$$\begin{aligned} \kappa_{2j} &= \frac{B_{2j}}{2j}\left[\sum_{s=1}^{N} s^{2j} - \sum_{i=1}^{k}\sum_{s=1}^{n_i} s^{2j}\right] \\ &= \frac{B_{2j}}{2j(2j+1)}\left[B_{2j+1}(N+1) + (k-1)B_{2j+1} - \sum_{i=1}^{k} B_{2j+1}(n_i+1)\right] \end{aligned}$$

and $\kappa_{2j+1} = 0$, $j \geq 1$, and B_{2j} and $B_{2j}(x)$ are the Bernoulli numbers and polynomials, respectively, of degree $2j$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", jonckheere_terpsta_s_continuous(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

Approximations

`ctx.`**`jterpsta_ft`**`(`*x*, *n*, *results='cdf'*`)`

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the pdf, cdf and sf from the characteristic function (see *pmf_from_cf_lattice()* and *cdf_from_cf_lattice()*).

`ctx.`**`jterpsta_ecf`**`(`*x*, *f*, *rho*, *omega*`)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Edgeworth approximation to the pdf, cdf and sf.

`ctx.jterpsta_ecf_inv`(*q*, *f* , *rho*, *omega*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Cornish-Fisher approximation to the qtf and isf.

`ctx.jterpsta_spa`(*x*, *n*, *results='c'*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the Luggannini-Rice saddlepoint approximation of the pdf, cdf and sf.

The saddlepoint s is determined numerically using Newton iterations, with a starting value of $s = 0.1$.

`ctx.jterpsta_spa_inv`(*x*, *n*, *results='qtf'*)

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

4.14.8 Generalized Page L distribution, continuous data

class ctx.**dist_page_l**(k, n)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of Page's L is a discrete (lattice) probability distribution with k samples of size $n_1 \geq 1, \ldots, n_k \geq 1$ and the support interval $(0, nm))$. See also Wikipedia [1183], Noether [425], vandeWiel [791] .

Consider k independent groups X_i of sizes $n_i, i = 1 \ldots k$. The Page L statistic is defined as

$$L = ??$$

dist_page_l.**pmf**(x)

Returns $\text{pmf}_X(x)$, the probability mass function (pmf) of a random variable X, following a generalized Page L distribution.

$$\text{pmf}_X(x) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pmf: ", page_l_continuous(mu, sigma).pmf(x))
6.3563523462564525615615615614561356E-20
```

dist_page_l.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a generalized Page L distribution.

$$\text{cdf}_X(x) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", page_l_continuous(mu, sigma).pmf(x))
6.3563523462564525615615615614561356E-20
```

dist_page_l.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following a generalized Page L distribution:

$$\text{sf}_X(x) = 1 - \text{cdf}_X(x)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", page_l_continuous(mu, sigma).pmf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_page_l.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a generalized Page L distribution. There is no closed form for the qtf: It is computed with Newton iterations where the starting values are from Boost.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", page_l_continuous(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145614356E+00
```

dist_page_l.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a generalized Page L distribution:

$$\text{isf}_X(q) = \text{qtf}_X(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", page_l_continuous(mu, sigma).isf(q))
6.35635234625645256156156145614356E+00
```

dist_page_l.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a generalized Page L distribution:

$$C_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", page_l_continuous(mu, sigma).c_x(t))
6.35635234625645256156156145614356E+00
```

dist_page_l.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a generalized Page L distribution:

$$M_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", page_l_continuous(mu, sigma).c_x(t))
6.35635234625645256156156145614356E+00
```

dist_page_l.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a generalized Page L distribution:

$$K_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", page_l_continuous(mu, sigma).k_x(t, k))
6.35635234625645256156156145614356E+00
```

`dist_page_l.moments(k)`

Returns the first j moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a generalized Page L distribution (Wikipedia). The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", page_l_continuous(mu, sigma).moments(k))
6.356352346256452561561561456135 6E+00
```

`dist_page_l.cumulants(k)`

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a generalized Page L distribution. The cumulants of J_N are given by :

$$\kappa_{2j} = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", page_l_continuous(mu, sigma).cumulants(k))
6.356352346256452561561561456135 6E+00
```

Approximations

`ctx.page_ecf(x, f, rho, omega)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Edgeworth approximation to the pdf, cdf and sf.

For the Page L distribution, the cumulants are calculated from the pmf

`ctx.page_ecf_inv(q, f, rho, omega)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Cornish-Fisher approximation to the qtf and isf.

For the Page L distribution, the cumulants are calculated from the pmf

`ctx.page_spa(x, n, results='c')`

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the Luggannini-Rice saddlepoint approximation of the pdf, cdf and sf.

$K_X(t)$, the cumulant generating function, and its j^{th} derivatives, $K_X^{(j)}(t), j = 1 \ldots k$, of a random variable X, following a Jonckheere-Terpsta S distribution, are calculated from the pgf. The saddlepoint s is determined numerically using Newton iterations, with a starting value of $s = 0.1$.

`ctx.page_spa_inv(x, n, results='qtf')`

where `ctx` is `fpm`, `mpm`, `ipm`, `dec`, `gmp` or `apm`.

Calculates the inverse Jensen saddlepoint approximation of the qtf and isf.

4.14.9 Noncentral generalized Page L distribution, Milton alternatives

class ctx.**dist_page_l_nc_milton**(k, n)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of Page's L is a discrete (lattice) probability distribution with k samples of size $n_1 \geq 1, \ldots, n_k \geq 1$ and the support interval $(0, nm)$). See also Wikipedia [1183], Noether [425], vandeWiel [791] .

Consider k independent groups X_i of sizes $n_i, i = 1 \ldots k$. The Page L statistic is defined as

$$L = ??$$

dist_page_l_nc_milton.**pmf**(x)

Returns $\text{pmf}_X(x)$, the probability mass function (pmf) of a random variable X, following a Page L distribution under Milton alternatives.

$$\text{pmf}_X(x) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pmf: ", page_l_nc_milton_continuous(mu, sigma).pmf(x))
6.3563523462564525615615615614561356E-20
```

dist_page_l_nc_milton.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Page L distribution under Milton alternatives.

$$\text{cdf}_X(x) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", page_l_nc_milton_continuous(mu, sigma).pmf(x))
6.3563523462564525615615615614561356E-20
```

dist_page_l_nc_milton.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following a Page L distribution under Milton alternatives:

$$\text{sf}_X(x) = 1 - \text{cdf}_X(x)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", page_l_nc_milton_continuous(mu, sigma).pmf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_page_l_nc_milton.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Page L distribution under Milton alternatives. There is no closed form for the qtf: It is computed with Newton iterations where the starting values are from Boost.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", page_l_nc_milton_continuous(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_page_l_nc_milton.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Page L distribution under Milton alternatives:

$$\text{isf}_X(q) = \text{qtf}_X(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", page_l_nc_milton_continuous(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_page_l_nc_milton.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Page L distribution under Milton alternatives:

$$C_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", page_l_nc_milton_continuous(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_page_l_nc_milton.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a Page L distribution under Milton alternatives:

$$M_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", page_l_nc_milton_continuous(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_page_l_nc_milton.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a Page L distribution under Milton alternatives:

$$K_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", page_l_nc_milton_continuous(mu, sigma).k_x(t, k))
6.35635234625645256156156145613356E+00
```

dist_page_l_nc_milton.**moments**(k)

Returns the first j moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Page L distribution under Milton alternatives (Wikipedia). The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", page_l_nc_milton_continuous(mu, sigma).moments(k))
6.35635234625645256156156145613356E+00
```

dist_page_l_nc_milton.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a Page L distribution under Milton alternatives. The cumulants of J_N are given by :

$$\kappa_{2j} = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", page_l_nc_milton_continuous(mu, sigma).cumulants(k))
6.35635234625645256156156145613356E+00
```

4.15 Discrete (non-lattice) distributions related to rank tests

4.15.1 Cochran-Friedman-Quade distribution

class ctx.**dist_friedman**(k, n)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of the Cochran-Friedman-Quade tests is a discrete (non-lattice) probability distribution with k samples of size $n_1 \geq 1, \ldots, n_k \geq 1$ and the support interval $(0, nm))$. See also Wikipedia [1183], Noether [425], vandeWiel [791] .

Consider k independent groups X_i of sizes $n_i, i = 1 \ldots k$. The Page L statistic is defined as

$$L = ??$$

dist_friedman.**pmf**(x)

Returns $\text{pmf}_X(x)$, the probability mass function (pmf) of a random variable X, following a Page L distribution. Let $p(n_1, \ldots, n_k; t) = \Pr[J_N = t]$. If J_N is based on k independent samples of sizes $n_1, \ldots, n_k$, then (Skillings 1980):

$$p(n_1, \ldots, n_k; t) = ??$$

where the sum is over all x with positive $p(\cdot)$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pmf: ", friedman_continuous(mu, sigma).pmf(x))
6.3563523462564525615615615614561356E-20
```

dist_friedman.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Page L distribution. Let $p(n_1, \ldots, n_k; t) = \Pr[J_N = t]$. If J_N is based on k independent samples of sizes $n_1, \ldots, n_k$, then (Skillings 1980):

$$p(n_1, \ldots, n_k; t) = ??$$

where the sum is over all x with positive $p(\cdot)$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", friedman_continuous(mu, sigma).pmf(x))
6.3563523462564525615615615614561356E-20
```

dist_friedman.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following a Page L distribution:

$$\text{sf}_X(x) = 1 - \text{cdf}_X(x)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", friedman_continuous(mu, sigma).pmf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_friedman.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Page L distribution. There is no closed form for the qtf: It is computed with Newton iterations where the starting values are from Boost.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", friedman_continuous(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_friedman.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Page L distribution:

$$\text{isf}_X(q) = \text{qtf}_X(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", friedman_continuous(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_friedman.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Page L distribution:

$$C_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", friedman_continuous(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_friedman.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a Page L distribution:

$$M_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", friedman_continuous(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_friedman.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a Page L distribution:

$$K_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", friedman_continuous(mu, sigma).k_x(t, k))
6.356352346256452561561561456l356E+00
```

dist_friedman.**moments**(k)

Returns the first j moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Page L distribution (Wikipedia). The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", friedman_continuous(mu, sigma).moments(k))
6.356352346256452561561561456l356E+00
```

dist_friedman.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a Page L distribution. The cumulants of J_N are given by :

$$\kappa_{2j} = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", friedman_continuous(mu, sigma).cumulants(k))
6.356352346256452561561561456l356E+00
```

4.15.2 Kruskal-Wallis distribution

class ctx.**dist_kruskal_wallis**(k, n)

where ctx is fpm, mpm, ipm, dec, gmp or apm.

The distribution of the Kruskal-Wallis test is a discrete (non-lattice) probability distribution with k samples of size $n_1 \geq 1, \ldots, n_k \geq 1$ and the support interval $(0, nm))$. See also Wikipedia [1183], Noether [425], vandeWiel [791] .

Consider k independent groups X_i of sizes $n_i, i = 1 \ldots k$. The Kruskal_Wallis statistic is defined as

$$L = ??$$

dist_kruskal_wallis.**pmf**(x)

Returns $\text{pmf}_X(x)$, the probability mass function (pmf) of a random variable X, following a Kruskal-Wallis distribution. Let $p(n_1, \ldots, n_k; t) = \Pr[J_N = t]$. If J_N is based on k independent samples of sizes $n_1, \ldots, n_k$, then (Skillings 1980):

$$p(n_1, \ldots, n_k; t) = ??$$

where the sum is over all x with positive $p(\cdot)$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("pmf: ", kruskal_wallis_continuous(mu, sigma).pmf(x))
6.3563523462564525615615615614561356E-20
```

dist_kruskal_wallis.**cdf**(x)

Returns $\text{cdf}_X(x)$, the cumulative distribution function (cdf) of a random variable X, following a Kruskal-Wallis distribution. Let $p(n_1, \ldots, n_k; t) = \Pr[J_N = t]$. If J_N is based on k independent samples of sizes $n_1, \ldots, n_k$, then (Skillings 1980):

$$p(n_1, \ldots, n_k; t) = ??$$

where the sum is over all x with positive $p(\cdot)$.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print ("cdf: ", kruskal_wallis_continuous(mu, sigma).pmf(x))
6.3563523462564525615615615614561356E-20
```

dist_kruskal_wallis.**sf**(x)

Returns $\text{sf}_X(x)$, the survival function (sf) of a random variable X, following a Kruskal-Wallis distribution:

$$\text{sf}_X(x) = 1 - \text{cdf}_X(x)$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; x = 3;
>>> print (" sf: ", kruskal_wallis_continuous(mu, sigma).pmf(x))
sf: 6.3563523462564525615615615614561356E-20
```

dist_kruskal_wallis.**qtf**(q)

Returns $\text{qtf}_X(x)$, the quantile function (qtf) of a random variable X, following a Kruskal-Wallis distribution. There is no closed form for the qtf: It is computed with Newton iterations where the starting values are from Boost.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("qtf: ", kruskal_wallis_continuous(mu, sigma).qtf(q))
qtf: 6.35635234625645256156156145613 56E+00
```

dist_kruskal_wallis.**isf**(q)

Returns $\text{isf}_X(q)$, the inverse survival function (isf) of a random variable X, following a Kruskal-Wallis distribution:

$$\text{isf}_X(q) = \text{qtf}_X(1-q).$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; q = 0.3;
>>> print ("isf: ", kruskal_wallis_continuous(mu, sigma).isf(q))
6.35635234625645256156156145613 56E+00
```

dist_kruskal_wallis.**c_x**(t)

Returns $C_X(t)$, the characteristic function of a random variable X, following a Kruskal-Wallis distribution:

$$C_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("c_x: ", kruskal_wallis_continuous(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_kruskal_wallis.**m_x**(t)

Returns $M_X(t)$, the moment generating function of a random variable X, following a Kruskal-Wallis distribution:

$$M_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3;
>>> print ("m_x: ", kruskal_wallis_continuous(mu, sigma).c_x(t))
6.35635234625645256156156145613 56E+00
```

dist_kruskal_wallis.**k_x**(t, *k=0*)

Returns $K_X(t)$, the cumulant generating function of a random variable X, following a Kruskal-Wallis distribution:

$$K_X(t) = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; t = 0.3; k = 6;
>>> print ("c_x: ", kruskal_wallis_continuous(mu, sigma).k_x(t, k))
6.35635234625645256156156145613 56E+00
```

dist_kruskal_wallis.**moments**(k)

Returns the first j moments, $\mu_j, j = 1 \ldots k$, of a random variable X, following a Kruskal-Wallis distribution (Wikipedia). The moments are calculated from the cumulants.

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", kruskal_wallis_continuous(mu, sigma).moments(k))
6.35635234625645256156156145613 56E+00
```

dist_kruskal_wallis.**cumulants**(k)

Returns the first j cumulants, $\kappa_j, j = 1 \ldots k$, of a random variable X, following a Kruskal-Wallis distribution. The cumulants of J_N are given by :

$$\kappa_{2j} = ??$$

```
>>> from xlcalcnet import *
>>> mp.dps = 30
>>> mu = 0; sigma = 1; k = 6;
>>> print ("saddlepoint: ", kruskal_wallis_continuous(mu, sigma).cumulants(k))
6.35635234625645256156156145613 56E+00
```

CHAPTER

FIVE

NUMERICAL CALCULUS

The source code for the C# tests in Visual Studio is divided by in 2 parts:

Part 1 contains procedures from DAMath, Boost Math, Boost Odeint and Eigen. The source code for the C# tests in Visual Studio can be found online in the `XlCalcNet` repository or in the corresponding local `XlCalcNet` folder in the file B05a_NumericalCalculus.cs.

Part 2 is devoted to numerical integration in ball arithmetic. The source code for the C# tests in Visual Studio can be found online in the `XlCalcNet` repository or in the corresponding local `XlCalcNet` folder in the file B05b_FlintNumericalCalculus.cs.

5.1 Introduction

5.1.1 Delegates, lambda expressions, callback functions: an example

Returns a local minimum of the function f in the interval (a, b), implementing Brent's algorithm.

See also: Wikipedia [1088], Zhang [1502], Brent [36]

x is the approximate minimum abscissa, fx=f(x). eps and t define a tolerance tol =eps*|x|+t. f is never evaluated for 2 points closer together than tol. eps shall not be less than 2*eps_x, preferably not smaller than sqrt(eps_x). ic is the iteration count, -1 if a=b, 0 if max. count = 5000 exceeded. The algorithm combines golden section search and successive parabolic interpolation using only function (not derivative) evaluations.

Parameters:

f
: the function for which a local minimum is to be found.

a
: left border of the interval (a, b).

b
: right border of the interval (a, b).

eps
: defines a tolerance tol = $\epsilon|x|+$ t.

tol
: defines a tolerance tol = $\epsilon|x|+$ t.

Results:

x
: the approximate minimum abscissae.

fx
: fx = f(x).

ic
: the iteration count, -1 if a=b, 0 if max. count = 5000 exceeded.

5.1.2 Usage in Python

The routine in Python, using a local function definition. This form allows monitoring of the calls into the function (by un-commenting the `print` statement), but variables and functions local to the calling function cannot be accessed:

```
>>> from xlcalcnet import ereal
>>> a = -10.0; b = 20.0; eps = 1E-8; tol = 1E-8
>>> f = lambda x: -ereal.Exp(-x * x)
>>> res = ereal.LocalMin(f, a, b, eps, tol)
>>> print('res: (x0, fx0, ic1):', res)
```

The same routine in Python, using a local function definition. This form allows monitoring of the calls into the function (by un-commenting the `print` statement). Variables and functions local to the calling function can be accessed:

```
a = -10.0; b = 20.0; eps = 1E-8; tol = 1E-8
f = lambda x: -ereal.Exp(-x * x)
print('ereal.LocalMin')
res3 = ereal.LocalMin(f, a, b, eps, tol)
print('res3: (x0, fx0, ic1):', res3)
print()
print()
```

The same routine in Python, using a lambda expression. Variables and functions local to the calling function can be accessed:

```
a = -10.0; b = 20.0; eps = 1E-8; tol = 1E-8
f = lambda x: -ereal.Exp(-x * x)
print('ereal.LocalMin')
res3 = ereal.LocalMin(f, a, b, eps, tol)
print('res3: (x0, fx0, ic1):', res3)
print()
print()
```

The same routine in Python, inserting the lambda expression into `ereal.LocalMin`. Variables and functions local to the calling function can be accessed from within the lambda expression:

```
a = -10.0; b = 20.0; eps = 1E-8; tol = 1E-8
f = lambda x: -ereal.Exp(-x * x)
print('ereal.LocalMin')
res3 = ereal.LocalMin(lambda x: -ereal.Exp(-x * x), a, b, eps, tol)
print('res3: (x0, fx0, ic1):', res3)
print()
print()
```

5.1.3 Usage in CSharp

The same routine in CSharp, using a callback function definition outside of the scope of the calling function. This form allows the callback function to be called from other functions as well, and it supports monitoring of the calls into the function (by un-commenting the `Console.WriteLine` statement), but variables, functions and subroutines local to the calling function cannot be accessed:

```
public static ereal XF1(ereal x)
{
    var y = -ereal.Exp(-x * x);
    //Console.WriteLine("x: {0},   y: {1}", x, y)
    return y;
}

public static void DemoLocalMin()
{
    var a = -10; var b = 20; var eps = 1E-10; var tol = 1E-10;
    var Res1 = ereal.LocalMin(XF1, a, b, eps, tol);
    Console.WriteLine("Res1:(x, fx, ic) {0}", Res1);
}
```

The same routine in CSharp, using a multi-line lambda expression to define the callback function. Note that in contrast to Python, in CSharp a lambda expression can contain not only expressions but also statements, including a `return` statement. This is functionally equivalent to defining a local function without the need to create a new class. Variables, functions and subroutines local to the calling function can be accessed from within the lambda expression. The function which is defined by the lambda expression can be called locally. In this form the lambda expression allows monitoring of the calls into the callback function (by un-commenting the `Console.WriteLine` statement):

```
public static void DemoLocalMin2()
{
    var a = -10; var b = 20; var eps = 1E-10; var tol = 1E-10;
    var F2 = ereal (ereal x) =>
    {
        var y = -ereal.Exp(-x * x);
        //Console.WriteLine("x: {0},   y: {1}", x, y)
        return y;
    };
    var Res1 = ereal.LocalMin(F2, a, b, eps, tol);
    Console.WriteLine("Res1:(x, fx, ic) {0}", Res1);
}
```

The same routine in CSharp, using a single-line lambda expression to define the callback function. Note that there is no `return` statement, and the return type of the function is not specified but inferred from the function expression. Variables, functions and subroutines local to the calling function can be accessed from within the lambda expression. The function which is defined by the lambda expression can be called locally. Monitoring of calls into the callback function is not supported:

```
public static void DemoLocalMin3()
{
    var a = -10; var b = 20; var eps = 1E-10; var tol = 1E-10;
    var F3 = (ereal x) => -ereal.Exp(-x * x);
    var Res1 = ereal.LocalMin(F3, a, b, eps, tol);
    Console.WriteLine("Res1:(x, fx, ic) {0}", Res1);
}
```

The same routine in CSharp, using an anonymous lambda expression, which is like a single line lambda expression inserted directly into `ereal.LocalMin`. Variables and functions local to the calling function can be accessed from within the lambda expression. Since an anonymous lambda expression does not have a name, it cannot be called locally. Monitoring of calls into the callback function is not supported:

```
public static void DemoLocalMin4()
{
    var a = -10; var b = 20; var eps = 1E-10; var tol = 1E-10;
    var Res1 = ereal.LocalMin((ereal x) => -ereal.Exp(-x * x), a, b, eps, tol);
    Console.WriteLine("Res1:(x, fx, ic) {0}", Res1);
}
```

All of the above CSharp routines produce the following output:

```
Res1:(x, fx, ic) (-1.000175554142801716 0E-10, -1.0000000000000000000, 14)
```

5.2 DAMath: Numerical Rootfinding and Minimization

5.2.1 Quadratic Equation, Real Coefficients

`ctx.squadx`(a, b, c)

where `ctx` is `math53`. Solves the quadratic equation $ax^2 + bx + c = 0$.

Parameters

- **a** – real coeffient in the quadratic equation.
- **b** – real coeffient in the quadratic equation.
- **c** – real coeffient in the quadratic equation.

Returns

a tuple (*z1, z2*), where *z1* is the first complex root.and *z2* is the second complex root.

See also: Wikipedia [1099], MathWorld [813].

```
>>> from xlcalcnet import math53
>>> a = -13;  b = 4;  c = 5
>>> ic, x1, y1, x2, y2 = ctx.squadx(a,b,c)
>>> print("ic: ", ic,"x1: ", x1,"y1: ", y1,"x2: ", x2,"y2: ", y2)
```

```
Quadratic
Return Code:  2
x1:  -0.4851249125321596 y1:  0.0
x2:  0.7928172202244673 y2:  0.0
```

5.2.2 Cubic Equation, Real Coefficients

`ctx.cubsolve`(a, b, c, d)

where `ctx` is `math53`. Solves the cubic equation $ax^3 + bx^2 + cx + d = 0$.

Parameters

- **a** – real coeffient in the cubic equation.
- **b** – real coeffient in the cubic equation.
- **c** – real coeffient in the cubic equation.
- **d** – real coeffient in the cubic equation.

Returns

a tuple (*x, z1, z2*), where *x* is the real root, *z1* is the first complex root and *z2* is the second complex root.

See also: Wikipedia [1090], MathWorld [800].

```
>>> from xlcalcnet import math53
>>> a = -13; b = 4; c = 5; d = 1
>>> x0, x1, y1, x2, y2 = ctx.cubsolve(a,b,c,d)
>>> print("x0: ", x0,"x1: ", x1,"y1: ", y1,"x2: ", x2,"y2: ", y2)
```

```
Cubic
x:  0.8593905490844492
x1:  -0.27584912069607076 y1:  -0.11582803026356575
x2:  -0.27584912069607076 y2:  0.11582803026356575
```

5.2.3 Brent's algorithm for finding a local minimum

`ctx.localmin`(*f*, *a*, *b*, *eps*, *t*)

where `ctx` is `math53`. Returns a local minimum of the function *f* in the interval (a, b), implementing Brent's algorithm.

Parameters

- **f** – the function for which a local minimum is to be found.
- **a** – the left border of the search interval.
- **b** – the right border of the search interval.
- **eps** – defines a tolerance eps*|x| + tol; eps should not be less than 2*eps_x, preferably not smaller than sqrt(eps_x).
- **tol** – defines a tolerance eps*|x| + tol.

Returns

a tuple (*localmin, fx, ic*), where *localmin* is an approximation to a local minimum; *fx* = f(localmin); and *ic* is the iteration count, -1 if a=b, 0 if max.=5000 exceeded.

See also: Wikipedia [1088], Zhang [1502], Brent [36]

x is the approximate minimum abscissa, fx=f(x). eps and t define a tolerance tol =eps*|x|+t. f is never evaluated for 2 points closer together than tol. eps shall not be less than 2*eps_x, preferably not smaller than sqrt(eps_x). ic is the iteration count, -1 if a=b, 0 if max. count = 5000 exceeded. The algorithm combines golden section search and successive parabolic interpolation using only function (not derivative) evaluations.

Examples in Python

The routine in Python, using a local function definition. This form allows monitoring of the calls into the function (by un-commenting the `print` statement), but variables and functions local to the calling function cannot be accessed:

```
>>> from xlcalcnet import ereal
>>> a = -10.0; b = 20.0; eps = 1E-8; tol = 1E-8
>>> f = lambda x: -ereal.Exp(-x * x)
>>> res = ereal.LocalMin(f, a, b, eps, tol)
>>> print('res: (x0, fx0, ic1):', res)
```

The same routine in Python, using a local function definition. This form allows monitoring of the calls into the function (by un-commenting the `print` statement). Variables and functions local to the calling function can be accessed:

```
a = -10.0; b = 20.0; eps = 1E-8; tol = 1E-8
f = lambda x: -ereal.Exp(-x * x)
print('ereal.LocalMin')
res3 = ereal.LocalMin(f, a, b, eps, tol)
print('res3: (x0, fx0, ic1):', res3)
print()
print()
```

The same routine in Python, using a lambda expression. Variables and functions local to the calling function can be accessed:

```
a = -10.0; b = 20.0; eps = 1E-8; tol = 1E-8
f = lambda x: -ereal.Exp(-x * x)
print('ereal.LocalMin')
res3 = ereal.LocalMin(f, a, b, eps, tol)
print('res3: (x0, fx0, ic1):', res3)
print()
print()
```

The same routine in Python, inserting the lambda expression into `ereal.LocalMin`. Variables and functions local to the calling function can be accessed from within the lambda expression:

```
a = -10.0; b = 20.0; eps = 1E-8; tol = 1E-8
f = lambda x: -ereal.Exp(-x * x)
print('ereal.LocalMin')
res3 = ereal.LocalMin(lambda x: -ereal.Exp(-x * x), a, b, eps, tol)
print('res3: (x0, fx0, ic1):', res3)
print()
print()
```

Examples in CSharp

The same routine in CSharp, using a callback function definition outside of the scope of the calling function. This form allows the callback function to be called from other functions as well, and it supports monitoring of the calls into the function (by un-commenting the `Console.WriteLine` statement), but variables, functions and subroutines local to the calling function cannot be accessed:

```
public static ereal XF1(ereal x)
{
    var y = -ereal.Exp(-x * x);
    //Console.WriteLine("x: {0},   y: {1}", x, y)
    return y;
}

public static void DemoLocalMin()
{
    var a = -10; var b = 20; var eps = 1E-10; var tol = 1E-10;
    var Res1 = ereal.LocalMin(XF1, a, b, eps, tol);
    Console.WriteLine("Res1:(x, fx, ic) {0}", Res1);
}
```

The same routine in CSharp, using a multi-line lambda expression to define the callback function. Note that in contrast to Python, in CSharp a lambda expression can contain not only expressions but also statements, including a `return` statement. This is functionally equivalent to defining a local function without the need to create a new class. Variables, functions and subroutines local to the calling function can be accessed from within the lambda expression. The function which is defined by the lambda expression can be called locally. In this form the lambda expression allows monitoring of the calls into the callback function (by un-commenting the `Console.WriteLine` statement):

```
public static void DemoLocalMin2()
{
    var a = -10; var b = 20; var eps = 1E-10; var tol = 1E-10;
    var F2 = ereal (ereal x) =>
    {
        var y = -ereal.Exp(-x * x);
        //Console.WriteLine("x: {0},   y: {1}", x, y)
        return y;
    };
    var Res1 = ereal.LocalMin(F2, a, b, eps, tol);
    Console.WriteLine("Res1:(x, fx, ic) {0}", Res1);
}
```

The same routine in CSharp, using a single-line lambda expression to define the callback function. Note that there is no `return` statement, and the return type of the function is not specified but inferred from the function expression. Variables, functions and subroutines local to the calling function can be accessed from within the lambda expression. The function which is defined by the lambda expression can be called locally. Monitoring of calls into the callback function is not supported:

```
public static void DemoLocalMin3()
{
    var a = -10; var b = 20; var eps = 1E-10; var tol = 1E-10;
    var F3 = (ereal x) => -ereal.Exp(-x * x);
    var Res1 = ereal.LocalMin(F3, a, b, eps, tol);
    Console.WriteLine("Res1:(x, fx, ic) {0}", Res1);
}
```

The same routine in CSharp, using an anonymous lambda expression, which is like a single line lambda expression inserted

directly into `ereal.LocalMin`. Variables and functions local to the calling function can be accessed from within the lambda expression. Since an anonymous lambda expression does not have a name, it cannot be called locally. Monitoring of calls into the callback function is not supported:

```
public static void DemoLocalMin4()
{
    var a = -10; var b = 20; var eps = 1E-10; var tol = 1E-10;
    var Res1 = ereal.LocalMin((ereal x) => -ereal.Exp(-x * x), a, b, eps, tol);
    Console.WriteLine("Res1:(x, fx, ic) {0}", Res1);
}
```

All of the above CSharp routines produce the following output:

```
Res1:(x, fx, ic) (-1.000175554142801716 0E-10, -1.000000000000000000 0, 14)
```

5.2.4 Modified Brent's algorithm for finding a local minimum

`ctx.mbrent`(*f*, *a*, *b*, *t*)

where `ctx` is `math53`. Returns a local minimum of the function *f* in the interval (a, b), implementing a modified (simplified) version of Brent's algorithm as in procedure localmin with fixed eps=0.5*sqrt(eps_x).

Parameters

- **f** – the function for which a local minimum is to be found.
- **a** – the left border of the search interval.
- **b** – the right border of the search interval.
- **tol** – defines a tolerance eps*|x| + tol.

Returns

a tuple (*localmin, fx, ic*), where *localmin* is an approximation to a local minimum; *fx* = f(localmin); and *ic* is the iteration count, -1 if a=b, 0 if max.=5000 exceeded.

See also: Wikipedia [1088], Zhang [1502], Brent [36], BoostMath [47].

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> a = -10.0; b = 20.0; tol = 1E-8
>>> f = lambda x: -ereal.Exp(-x * x)
>>> res = ereal.MBrent(f, a, b, tol)
>>> print('res4: (x0, fx0, ic1):', res4)
```

5.2.5 Rootfinding: Brent/Dekker algorithm

`ctx.zbrent`(f, a, b, t)

where `ctx` is `math53`. Performs the Brent/Dekker algorithm with guaranteed convergence for finding a zero of a function,; assumes that f(a) and f(b) have different signs.

Parameters

- **f** – the function for which a zero is sought.
- **a** – the left border of the search interval.
- **b** – the right border of the search interval.
- **tol** – defines a tolerance 6 * eps_x * $|x|$ +2*tol.

Returns

a tuple (*root, ic, err*), where *root* is an approximation to a zero (root) of the function; *ic* is the iteration count, -1 if a=b, 0 if max.=5000 exceeded; and *err* is the error code (0: no error, -1: if f(a) and f(b) have the same sign, -2: max. iteration count exceeded).

Brent/Dekker algorithm with guaranteed convergence for finding a zero of a function: Return a zero x of the function f in the interval [a,b] to within a tolerance 6*eps_x*|x|+2*t, where t is a positive tolerance; assumes that f(a) and f(b) have different signs. ic is the iteration count; err is an error code (0: no error, -1: if f(a) and f(b) have the same sign, -2: max. iteration count exceeded). The algorithm is based on a combination of successive interpolations and bisection.

See also: Wikipedia [1088], Zhang [1502], Brent [37], BoostMath [47].

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> a = -20.0; b = 20.0; tol = 1E-8
>>> f = lambda x: ereal.Exp(x) - 10
>>> res = ereal.ZBrent(f, a, b, tol)
>>> print('res5: (x0, ic1, err):', res5)
```

5.2.6 Rootfinding: Simplified Brent/Dekker algorithm

`ctx.zeroin`(f, a, b, t)

where `ctx` is `math53`. Performs a simplified version of the Brent/Dekker algorithm for finding a zero of a function; assumes that f(a) and f(b) have different signs.

Parameters

- **f** – the function for which a zero is sought.
- **a** – the left border of the search interval.
- **b** – the right border of the search interval.
- **tol** – defines a tolerance 6 * eps_x * $|x|$ +2*tol.

Returns

an approximation to a zero (root) of the function.

See also: Wikipedia [1088], Zhang [1502], Brent [37], BoostMath [47].

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> a = -20.0; b = 20.0; tol = 1E-8
>>> f = lambda x: ereal.Exp(x) - 10
>>> x0 = ereal.ZeroIn(f, a, b, tol)
>>> print('x0: ', x0)
```

5.3 Boost/Math: Root Finding and Minimization Algorithms

5.3.1 Root Finding Without Derivatives (TOM 748 algorithm)

`ctxboost.`**`BracketRoot`**(*f*, *guess*, *factor*, *is_rising*, *get_digits*, *maxit*)

where `ctx` is `ctxboost`.

Parameters

- **`f`** – the function for which a root is determined.
- **`guess`** – an intial guess.
- **`factor`** – a multiplication factor used when searching for the bracket.
- **`is_rising`** – an indicator whether the function is rising.
- **`get_digits`** – the targeted number of accurate digits.
- **`maxit`** – the maximal number of iterations.

Returns

a tuple (*root, error, iter*), where *root* is an approximation to a root of the function *f*, using the TOM 748 algorithm for finding a zero; *error* is an estimate of the modulus of the error of the approximation; and *iter* is the actual number of iterations.

See also: BoostMath [38], Alefeld *et al.* [8].

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> f = lambda x: x * x * x - 28
>>> guess = 2.33;  factor = 2.0; is_rising = True; get_digits = 64;  maxit = 20
>>> res = ereal.BracketRoot(f, guess, factor, is_rising, get_digits, maxit)
>>> print("res (x0, error, iter): ", res)
```

```
boost.bracket_root(f, guess, factor, is_rising, get_digits, maxit
result:  3.036588971875662
```

5.3.2 Root Finding With Derivatives: Newton-Raphson

`ctxboost.`**`NewtonRaphson`**(*f*, *df*, *guess*, *xmin*, *xmax*, *get_digits*, *maxit*)

where `ctx` is `ctxboost`.

Parameters

- **`f`** – the function for which a root is determined.
- **`df`** – the first derivative of the function *f*.
- **`guess`** – an intial guess.
- **`xmin`** – the left border of the search interval.
- **`xmax`** – the right border of the search interval.
- **`get_digits`** – the targeted number of accurate digits.
- **`maxit`** – the maximal number of iterations.

Returns

a tuple (*root, iter*), where *root* is an approximation to a root of the function *f* in the interval (*xmin, xmax*), using the Newton algorithm for finding a zero; and *iter* is the actual number of iterations.

See also: Wikipedia [1096], BoostMath [48], MathWorld [809].

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> f = lambda x: x * x * x - 28
>>> df1 = lambda x: 3 * x * x
>>> guess = 2.33; xmin = 1.0; xmax = 4.0; get_digits = 64;  maxit = 20
>>> result3 = ereal.NewtonRaphson(f, df1, guess, xmin, xmax, get_digits, maxit)
>>> print("res2 (x0, iter): ", result3)
```

```
boost.newton_raphson(f, df, guess, xmin, xmax, get_digits, maxit)
result:  3.0365889718756627
```

5.3.3 Root Finding With Derivatives: Halley

`ctxboost.`**`Halley`**(*f*, *df*, *d2f*, *guess*, *xmin*, *xmax*, *get_digits*, *maxit*)

where `ctx` is `ctxboost`.

Parameters

- **`f`** – the function for which a root is determined.
- **`df`** – the first derivative of the function *f*.
- **`df2`** – the second derivative of the function *f*.
- **`guess`** – an intial guess.
- **`xmin`** – the left border of the search interval.
- **`xmax`** – the right border of the search interval.
- **`get_digits`** – the targeted number of accurate digits.
- **`maxit`** – the maximal number of iterations.

Returns

a tuple (*root, iter*), where *root* is an approximation to a root of the function *f* in the interval (*xmin, xmax*), using the Halley algorithm for finding a zero; and *iter* is the actual number of iterations.

See also: Wikipedia [1093], BoostMath [48], MathWorld [804].

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> f = lambda x: x * x * x - 28
>>> df1 = lambda x: 3 * x * x
>>> df2 = lambda x: 6 * x
>>> guess = 2.33; xmin = 1.0; xmax = 4.0; get_digits = 64;  maxit = 20
>>> res = ereal.Halley(f, df1, df2, guess, xmin, xmax, get_digits, maxit)
>>> print("res (x0, iter): ", res)
```

```
boost.halley(f, df, df2, guess, xmin, xmax, get_digits, maxit)
result:  3.0365889718756627
```

5.3.4 Root Finding With Derivatives: Schröder

`ctxboost.`**`Schroeder`**(*f*, *df*, *d2f*, *guess*, *xmin*, *xmax*, *get_digits*, *maxit*)

where `ctx` is `ctxboost`.

Parameters

- **`f`** – the function for which a root is determined.
- **`df`** – the first derivative of the function *f*.
- **`df2`** – the second derivative of the function *f*.
- **`guess`** – an intial guess.
- **`xmin`** – the left border of the search interval.
- **`xmax`** – the right border of the search interval.
- **`get_digits`** – the targeted number of accurate digits.
- **`maxit`** – the maximal number of iterations.

Returns

a tuple (*root, iter*), where *root* is an approximation to a root of the function *f* in the interval (*xmin, xmax*), using the Schröder algorithm for finding a zero; and *iter* is the actual number of iterations.

See also: BoostMath [48], MathWorld [814], Schröder [496].

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> f = lambda x: x * x * x - 28
>>> df1 = lambda x: 3 * x * x
>>> df2 = lambda x: 6 * x
>>> guess = 2.33; xmin = 1.0; xmax = 4.0; get_digits = 64;  maxit = 20
>>> res = ereal.Schroeder(f, df1, df2, guess, xmin, xmax, get_digits, maxit)
>>> print("res (x0, iter): ", res)
```

```
boost.schroder(f, df, df2, guess, xmin, xmax, get_digits, maxit)
result:  3.0365889718756627
```

5.3.5 Locating Function Minima using Brent's algorithm

`ctx.BrentMinimum`(*f*, *a*, *b*, *get_digits*, *maxit*)

where `ctx` is `ctxboost`.

Parameters

- **f** – the function for which a local minimum is determined.
- **a** – the left border of the search interval.
- **b** – the right border of the search interval.
- **get_digits** – the targeted number of accurate digits.
- **maxit** – the maximal number of iterations.

Returns

a tuple (*localmin, fx0, iter*), where *localmin* is an approximation to a local minimum of the function f in the interval (*a,b*), using Brent's algorithm; *fx0* is the value of *f(localmin)*; and *iter* is the number of iterations.

See also: Wikipedia [1088], Zhang [1502], Brent [36], BoostMath [47].

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> f = lambda x: (x + 3) * (x - 1) * (x - 1)
>>> bracket_min = 0.5; bracket_max = 1.5;  bits = 125;  maxit = 20
>>> res = ereal.Brent_Minimum(f, bracket_min, bracket_max, bits, maxit)
>>> print("res5 (x0, fx0, iter): ", result3)
```

```
boost.brent_minimum(f3, a, b, get_digits, maxit)
x0:  2.9086877250246185e-09
```

5.4 Mpmath: Rootfinding and optimization

5.4.1 General root-finding interface

`ctx.findroot`(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Find a solution to $f(x) = 0$, using *x0* as starting point or interval for *x*.

Multidimensional overdetermined systems are supported. You can specify them using a function or a list of functions.

If the found root does not satisfy $|f(x)|^2 \leq \mathrm{tol}$, an exception is raised (this can be disabled with *verify=False*).

Arguments

f
one dimensional function

x0
starting point, several starting points or interval (depends on solver)

tol
the returned solution has an error smaller than this

verbose
print additional information for each iteration if true

verify
verify the solution and raise a ValueError if $|f(x)|^2 > \mathrm{tol}$

solver
a generator for f and *x0* returning approximative solution and error

maxsteps
after how many steps the solver will cancel

df
first derivative of f (used by some solvers)

d2f
second derivative of f (used by some solvers)

multidimensional
force multidimensional solving

J
Jacobian matrix of f (used by multidimensional solvers)

norm
used vector norm (used by multidimensional solvers)

solver has to be callable with `(f, x0, **kwargs)` and return an generator yielding pairs of approximative solution and estimated error (which is expected to be positive). You can use the following string aliases: 'secant', 'mnewton', 'halley', 'muller', 'illinois', 'pegasus', 'anderson', 'ridder', 'anewton', 'bisect'

5.4.2 Bisection algorithm

`ctx.bisection`(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Find a solution to $f(x) = 0$, using *x0* as starting point or interval for *x*.

1d-solver generating pairs of approximative root and error. See also: Wikipedia [1087].

Uses bisection method to find a root of f in [a, b]. Might fail for multiple roots (needs sign change).

Pro:

- robust and reliable

Contra:

- converges slowly
- needs sign change

5.4.3 Secant algorithm

`ctx.secant`(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Find a solution to $f(x) = 0$, using *x0* as starting point or interval for *x*.

1d-solver generating pairs of approximative root and error. See also: Wikipedia [1102].

Needs starting points x0 and x1 close to the root. x1 defaults to x0 + 0.25.

Pro:

- converges fast

Contra:

- converges slowly for multiple roots

The function `findroot()` locates a root of a given function using the secant method by default. A simple example use of the secant method is to compute π as the root of $\sin x$ closest to $x_0 = 3$:

```
>>> from xlcalcnet import *
>>> mp.dps = 30; mp.pretty = True
>>> findroot(sin, 3)
3.14159265358979323846264338328
```

The secant method can be used to find complex roots of analytic functions, although it must in that case generally be given a nonreal starting value (or else it will never leave the real line):

```
>>> mp.dps = 15
>>> findroot(lambda x: x**3 + 2*x + 1, j)
(0.226698825758202 + 1.46771150871022j)
```

A nice application is to compute nontrivial roots of the Riemann zeta function with many digits (good initial values are needed for convergence):

```
>>> mp.dps = 30
>>> findroot(zeta, 0.5+14j)
(0.5 + 14.1347251417346937904572519836j)
```

The secant method can also be used as an optimization algorithm, by passing it a derivative of a function. The following example locates the positive minimum of the gamma function:

```
>>> mp.dps = 20
>>> findroot(lambda x: diff(gamma, x), 1)
1.4616321449683623413
```

5.4.4 Illinois, Pegasus, Anderson algorithms

`ctx.illinois`(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Find a solution to $f(x) = 0$, using *x0* as starting point or interval for x.

1d-solver generating pairs of approximative root and error. See also: Wikipedia [1094], Dowell and Jarratt [288], Wikipedia [1085].

Uses Illinois method or similar to find a root of f in [a, b]. Might fail for multiple roots (needs sign change). Combines bisect with secant (improved regula falsi).

The only difference between the methods is the scaling factor m, which is used to ensure convergence (you can choose one using the 'method' keyword):

Illinois method ('illinois'):
m = 0.5

Pegasus method ('pegasus'):
m = fb/(fb + fz)

Anderson-Bjoerk method ('anderson'):
m = 1 - fz/fb if positive else 0.5

Pro:

- converges very fast

Contra:

- has problems with multiple roots
- needs sign change

Intersection methods

When you need to find a root in a known interval, it's highly recommended to use an intersection-based solver like `'anderson'` or `'ridder'`. Usually they converge faster and more reliable. They have however problems with multiple roots and usually need a sign change to find a root:

```
>>> findroot(lambda x: x**3, (-1, 1), solver='anderson')
0.0
```

Be careful with symmetric functions:

```
>>> findroot(lambda x: x**2, (-1, 1), solver='anderson')
Traceback (most recent call last):
    ...
ZeroDivisionError
```

It fails even for better starting points, because there is no sign change:

```
>>> findroot(lambda x: x**2, (-1, .5), solver='anderson')
Traceback (most recent call last):
    ...
ValueError: Could not find root within given tolerance. (1.0 > 2.1684043449710088680 1e-19)
Try another starting point or tweak arguments.
```

5.4.5 Muller algorithm

`ctx.muller`(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Find a solution to $f(x) = 0$, using *x0* as starting point or interval for *x*.

1d-solver generating pairs of approximative root and error. See also: Wikipedia [1095].

Needs starting points x0, x1 and x2 close to the root. x1 defaults to x0 + 0.25; x2 to x1 + 0.25. Uses Muller's method that converges towards complex roots.

Pro:

- converges fast (somewhat faster than secant)
- can find complex roots

Contra:

- converges slowly for multiple roots
- may have complex values for real starting points and real roots

Complex roots

For complex roots it's recommended to use Muller's method as it converges even for real starting points very fast:

```
>>> findroot(lambda x: x**4 + x + 1, (0, 1, 2), solver='muller')
(0.727136084491197 + 0.934099289460529j)
```

5.4.6 Ridder algorithm

`ctx.ridder`(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Find a solution to $f(x) = 0$, using *x0* as starting point or interval for *x*.

1d-solver generating pairs of approximative root and error. See also: Wikipedia [1101].

Ridders' method to find a root of f in [a, b]. Is told to perform as well as Brent's method (see Wikipedia [1088]) while being simpler.

Pro:

- very fast
- simpler than Brent's method

Contra:

- two function evaluations per step
- has problems with multiple roots
- needs sign change

Finally, a useful application is to compute inverse functions, such as the Lambert W function which is the inverse of we^w, given the first term of the solution's asymptotic expansion as the initial value. In basic cases, this gives identical results to mpmath's built-in `lambertw` function:

```
>>> def lambert(x):
...     return findroot(lambda w: w*exp(w) - x, log(1+x))
...
>>> mp.dps = 15
```

(continues on next page)

(continued from previous page)

```
>>> lambert(1); lambertw(1)
0.567143290409784
0.567143290409784
>>> lambert(1000); lambert(1000)
5.2496028524016
5.2496028524016
```

5.4.7 Brent algorithm (to be implemented from Scipy brent)

`ctx.brent`(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Find a solution to $f(x) = 0$, using *x0* as starting point or interval for x.

5.4.8 Newton algorithm

`ctx.newton_c`(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

1d-solver generating pairs of approximative root and error. See also Wikipedia [1096], MathWorld [809].

Needs starting points x0 close to the root.

Pro:

- converges fast
- sometimes more robust than secant with bad second starting point

Contra:

- converges slowly for multiple roots
- needs first derivative
- 2 function evaluations per iteration

Multiple roots

For multiple roots all methods of the Newtonian family (including secant) converge slowly. Consider this example:

```
>>> f = lambda x: (x - 1)**99
>>> findroot(f, 0.9, verify=False)
0.918073542444929
```

Even for a very close starting point the secant method converges very slowly. Use `verbose=True` to illustrate this.

5.4.9 Newton-Steffenson algorithm (ANewton)

`ctx.newton_steffenson_c`(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

EXPERIMENTAL 1d-solver generating pairs of approximative root and error.

Uses Newton's method modified to use Steffensens method when convergence is slow. (I.e. for multiple roots.)

Steffensen's method for quadratic convergence of a linear converging sequence. See also Wikipedia [1103]. Don not use it for higher rates of convergence. It may even work for divergent sequences.

Definition: F(x) = (x*f(f(x)) - f(x)**2) / (f(f(x)) - 2*f(x) + x)

Multiple roots

For multiple roots all methods of the Newtonian family (including secant) converge slowly. Consider this example:

```
>>> f = lambda x: (x - 1)**99
>>> findroot(f, 0.9, verify=False)
0.918073542444929
```

Even for a very close starting point the secant method converges very slowly. Use `verbose=True` to illustrate this.

Alternatively you can use an experimental Newtonian solver that keeps track of the speed of convergence and accelerates it using Steffensen's method if necessary:

```
>>> findroot(f, -10, solver='anewton', verbose=True)
x:     -9.8888888888888888889
error: 0.11111111111111111111
converging slowly
x:     -9.77890011223344556678
error: 0.10998877665544332211
converging slowly
x:     -9.67002233332199662166
error: 0.10887778911448945119
converging slowly
accelerating convergence
x:     -9.562244329955107669
error: 0.107778003366888854764
converging slowly
x:     0.99999999999999999214
error: 10.562244329955107759
x:     1.0
error: 7.8598304758094664213e-18
ZeroDivisionError: canceled with x = 1.0
1.0
```

5.4.10 Modified Newton algorithm (MNewton)

`ctx.mnewton_c`(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

1d-solver generating pairs of approximative root and error. See also: Wikipedia [1096].

Needs starting point x0 close to the root. Uses modified Newton's method that converges fast regardless of the multiplicity of the root.

Pro:

- converges fast for multiple roots

Contra:

- needs first and second derivative of f
- 3 function evaluations per iteration

Multiple roots

For multiple roots all methods of the Newtonian family (including secant) converge slowly. Consider this example:

```
>>> f = lambda x: (x - 1)**99
>>> findroot(f, 0.9, verify=False)
0.918073542444929
```

Even for a very close starting point the secant method converges very slowly. Use `verbose=True` to illustrate this.

It is possible to modify Newton's method to make it converge regardless of the root's multiplicity:

```
>>> findroot(f, -10, solver='mnewton')
1.0
```

5.4.11 Halley algorithm

ctx.**halley_c**(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where ctx is dec, mpm, or gmp.

1d-solver generating pairs of approximative root and error. See also: Wikipedia [1093], MathWorld [804].

Needs a starting point x0 close to the root. Uses Halley's method with cubic convergence rate.

Pro:

- converges even faster the Newton's method
- useful when computing with *many* digits

Contra:

- needs first and second derivative of f
- 3 function evaluations per iteration
- converges slowly for multiple roots

5.4.12 Roots of a vector function (MDNewton, to be implemented)

ctx.**md_newton_c**(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where ctx is dec, mpm, or gmp.

Find the root of a vector function numerically using Newton's method.

f is a vector function representing a nonlinear equation system.

x0 is the starting point close to the root.

J is a function returning the Jacobian matrix for a point.

Supports overdetermined systems.

Use the 'norm' keyword to specify which norm to use. Defaults to max-norm. The function to calculate the Jacobian matrix can be given using the keyword 'J'. Otherwise it will be calculated numerically.

Please note that this method converges only locally. Especially for high- dimensional systems it is not trivial to find a good starting point being close enough to the root.

Multidimensional functions are also supported:

```
>>> f = [lambda x1, x2: x1**2 + x2,
...      lambda x1, x2: 5*x1**2 - 3*x1 + 2*x2 - 3]
>>> findroot(f, (0, 0))
[-0.618033988749895]
[-0.381966011250105]
>>> findroot(f, (10, 10))
[ 1.61803398874989]
[-2.61803398874989]
```

You can verify this by solving the system manually.

Please note that the following (more general) syntax also works:

```
>>> def f(x1, x2):
...     return x1**2 + x2, 5*x1**2 - 3*x1 + 2*x2 - 3
...
>>> findroot(f, (0, 0))
[-0.618033988749895]
[-0.381966011250105]
```

5.4.13 Levenberg-Marquardt algorithm

`ctx.levenberg_marquardt_c`(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

See also: https://lmfit.github.io/lmfit-py/

See also: https://github.com/lmfit/lmfit-py/tree/master

5.4.14 BFGS algorithm.

`ctx.bfgs_c`(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

See also: https://medium.com/@tru11631/bfgs-and-l-bfgs-with-code-2fcaeee7b225

5.4.15 L-BFGS algorithm.

`ctx.lbfgs_c`(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

See also: https://medium.com/@tru11631/bfgs-and-l-bfgs-with-code-2fcaeee7b225

5.4.16 Conjugate gradient.

`ctx.conj_grad_c`(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

5.5 DAMath: Numerical Quadrature

For a general overview, see: Wikipedia [1097], Wikipedia [1104], MathWorld [803], Wikipedia [1084].

5.5.1 General error codes for Amath integration functions, type 1

Amath integration functions which are NOT using the double exponential transformation return an error code `ier`, which has the following meaning:

`ier = 0`: Normal and reliable termination of the routine. It is assumed that the requested accuracy has been achieved.

`ier > 0`: Abnormal termination of the routine the estimates for integral and error are less reliable. It is assumed that the requested accuracy has not been achieved.

`ier = 1`: Maximum number of subdivisions allowed has been achieved. One can allow more subdivisions by increasing the value of limit (and taking the according dimension adjustments into account). However, if this yields no improvement it is advised to analyze the integrand in order to determine the integration difficulties. If the position of a local difficulty can be determined (e.g. singularity, discontinuity within the interval) one will probably gain from splitting up the interval at this point and calling the integrator on the subranges. If possible, an appropriate special-purpose integrator should be used, which is designed for handling the type of difficulty involved.

`ier = 2`: The occurrence of roundoff error is detected, which prevents the requested tolerance from being achieved. The error may be under-estimated.

`ier = 3`: Extremely bad integrand behaviour occurs at some points of the integration interval.

`ier = 4`: The algorithm does not converge. Roundoff error is detected in the extrapolation table. It is presumed that the requested tolerance cannot be achieved, and that the returned result is the best which can be obtained.

`ier = 5`: The integral is probably divergent, or slowly convergent. It must be noted that divergence can occur with any other value of ier.

`ier = 6`: The input is invalid, because epsabs <= 0 and epsrel < 50*eps_d. result, abserr, last are set to zero.

`ier = 7`: The input is invalid, limit < 0 or limit > QMAXLIM. result, abserr, last are set to zero.

`ier = 8`: Dynamic list vectors cannot be allocated. result, abserr, last are set to zero.

`ier = 9`: At least one limit a or b is NaN, or infinite a=b. result, abserr, last are set to NaN_d.

5.5.2 General error codes for Amath integration functions, type 2

Amath integration functions which are using the double exponential transformation return an error code `ier`, which has the following meaning:

`ier = 0`: Normal and reliable termination of the routine. It is assumed that the requested accuracy has been achieved.

`ier > 0`: Abnormal termination of the routine the estimates for integral and error are less reliable. It is assumed that the requested accuracy has not been achieved.

`ier = 1`: eps < 8*eps_x.

`ier = 2`: roundoff problems.

`ier = 3`: max. iterations, result/abserr have values.

5.5.3 Global adaptive quadrature by Forsythe, Malcolm, Moler (quanc8)

`ctx.quanc8`(*f*, *a*, *b*, *epsabs*, *epsrel*, *limit*)

where `ctx` is `math53`. Performs a global adaptive quadrature of f over (a,b) based on a Fortran subroutine by Forsythe, Malcolm, Moler.

Parameters

- **f** – the function for which the integral is determined.
- **a** – the left border of the integration interval.
- **b** – the right border of the integration interval.
- **abserr** – the absolute accuracy requested.
- **relerr** – the relative accuracy requested.

Returns

a tuple (*integral, err, flag, neval*), where *integral* is an approximation to the integral; *abserr* is an estimate of of the modulus of the absolute error; *neval* is the number of integrand evaluations; and *ier* is the error code (success=0, error > 0: see *General error codes for Amath integration functions, type 1*).

Include reference to Forsythe, Malcolm, Moler.

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> a = 0.0; b = 2.0; epsabs = 1E-8; epsrel = 0.0; limit = 0
>>> f = lambda x: ereal.Exp(-x * x / 2)
>>> result, abserr, neval, ier = ereal.Qags(f, a, b, epsabs, epsrel, limit)
>>> print("result: ", result, "abserr: ", abserr)
>>> print("neval: ", neval, "ier: ", ier)
```

5.5.4 21-point Gauss-Kronrod rule, finite interval (qags)

`ctx.qags`(*f*, *a*, *b*, *epsabs*, *epsrel*, *limit*)

where `ctx` is `math53`. Performs a global adaptive quadrature of f over (a,b) based on 21-point Gauss-Kronrod rule for the subintervals, with acceleration by Wynn's epsilon algorithm.

Parameters

- **f** – the function for which the integral is determined.
- **a** – the left border of the integration interval.
- **b** – the right border of the integration interval.
- **epsabs** – the absolute accuracy requested.
- **epsrel** – the relative accuracy requested.
- **limit** – upperbound on the no. of subintervals, 0: use DefLimit.

Returns

a tuple (*integral, abserr, neval, ier*), where *integral* is an approximation to the integral; *abserr* is an estimate of of the modulus of the absolute error; *neval* is the number of integrand evaluations; and *ier* is the error code (success=0, error > 0: see *General error codes for Amath integration functions, type 1*).

See also: Piessens *et al.* [471], Wikipedia [1098], Wikipedia [1112].

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> a = 0.0; b = 2.0; epsabs = 1E-8; epsrel = 0.0; limit = 0
>>> f = lambda x: ereal.Exp(-x * x / 2)
>>> result, abserr, neval, ier = ereal.Qags(f, a, b, epsabs, epsrel, limit)
>>> print("result: ", result, "abserr: ", abserr)
>>> print("neval: ", neval, "ier: ", ier)
```

5.5.5 15-point Gauss-Kronrod rule, infinite interval (qagi)

`ctx.qagi`(*f*, *bound*, *inf*, *epsabs*, *epsrel*, *limit*)

where `ctx` is `math53`. Performs a global adaptive quadrature of f over an infinite interval based on a transformed 15-point Gauss-Kronrod for the subintervals, with acceleration by Wynn's epsilon algorithm.

Parameters

- **f** – the function for which the integral is determined.
- **bound** – finite bound of integration range (if any).
- **inf** – indicating the kind of integration range involved: 1 corresponds to (bound, +infinity), -1 to (-infinity, bound), 2 to (-infinity, +infinity).
- **epsabs** – the absolute accuracy requested.
- **epsrel** – the relative accuracy requested.
- **limit** – upperbound on the no. of subintervals, 0: use DefLimit.

Returns

a tuple (*integral, abserr, neval, ier*), where *integral* is an approximation to the integral; *abserr* is an estimate of of the modulus of the absolute error; *neval* is the number of integrand evaluations; and *ier* is the error code (success=0, error > 0: see *General error codes for Amath integration functions, type 1*).

See also: Piessens *et al.* [471], Wikipedia [1098].

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> bound = 0.0; infcode = 2; epsabs = 1E-8; epsrel = 0.0; limit = 0
>>> f = lambda x: ereal.Exp(-x * x / 2)
>>> result, abserr, neval, ier = ereal.Qagi(f, bound, infcode, epsabs, epsrel, limit)
>>> print("result: ", result, "abserr: ", abserr)
>>> print("neval: ", neval, "ier: ", ier)
```

5.5.6 Cauchy principal value, finite interval (qawc)

`ctx.qawc`(*f*, *a*, *b*, *c*, *epsabs*, *epsrel*, *limit*)

where `ctx` is `math53`. Performs an adaptive quadrature of $f(x)/(x-c)$ over the finite interval (a, b) with the singularity at c and c not equal a or b. The routine calculates an approximation result to the Cauchy principal value.

Parameters

- **f** – the function for which the integral is determined.
- **a** – the left border of the integration interval.
- **b** – the right border of the integration interval.
- **c** – singularity, ier=6 if $c = a$ or $c = b$.
- **epsabs** – the absolute accuracy requested.
- **epsrel** – the relative accuracy requested.
- **limit** – upperbound on the no. of subintervals, 0: use DefLimit.

Returns

a tuple (*integral, abserr, neval, ier*), where *integral* is an approximation to the integral; *abserr* is an estimate of of the modulus of the absolute error; *neval* is the number of integrand evaluations; and *ier* is the error code (success=0, error > 0: see *General error codes for Amath integration functions, type 1*).

See also: https://maxima.sourceforge.io/docs/manual/maxima_100.html

See also: Piessens *et al.* [471], Wikipedia [1098], Wikipedia [1107].

The routine in Python:

```
# Qawc Example is missing
bound = 0.0; infcode = 2; epsabs = 1E-8; epsrel = 0.0; limit = 0
f = lambda x: ereal.Exp(-x * x / 2)
result, abserr, neval, ier = ereal.Qagi(f, bound, infcode, epsabs, epsrel, limit)
print("ereal.Qagi")
print("result: ", result, "abserr: ", abserr)
print("neval: ", neval, "ier: ", ier)
print()
```

5.5.7 Double Exponential (DE) transformation, finite interval (intde)

`ctx.intde`(*f*, *a*, *b*, *eps*)

where `ctx` is `math53`. Performs an automatic quadrature of f(x) over the finite interval (a,b)} using Double Exponential (DE) transformation.

Parameters

- **f** – the function for which the integral is determined.
- **a** – the left border of the integration interval.
- **b** – the right border of the integration interval.
- **eps** – the relative accuracy requested.

Returns

a tuple (*integral, abserr, neval, ier*), where *integral* is an approximation to the integral, if ier=0 or 3; *abserr* is an estimate of of the modulus of the absolute error, if ier=0 or 3; *neval* is the number of integrand evaluations; and *ier* is the error code (success=0, error > 0: see *General error codes for Amath integration functions, type 2*).

See also: Wikipedia [1121], Takahasi and Mori [512], Ooura and M. [450], Mori [416].

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> a = 0.0; b = 2.0; eps = 1E-8
>>> f = lambda x: ereal.Exp(-x * x / 2)
>>> result, abserr, neval, ier = ereal.Intde(f, a, b, eps)
>>> print("result: ", result, "abserr: ", abserr)
>>> print("neval: ", neval, "ier: ", ier)
```

5.5.8 DE transformation, infinite interval, no oscillatory factor (intdei)

`ctx.intdei`(*f*, *a*, *eps*)

where `ctx` is `math53`. Performs an automatic quadrature of f(x) over (a,INF) using Double Exponential transformation when f(x) has no oscillatory factor.

Parameters

- **f** – the function for which the integral is determined.
- **a** – the left border of the integration interval.
- **eps** – the relative accuracy requested.

Returns

a tuple (*integral, abserr, neval, ier*), where *integral* is an approximation to the integral, if ier=0 or 3; *abserr* is an estimate of of the modulus of the absolute error, if ier=0 or 3; *neval* is the number of integrand evaluations; and *ier* is the error code (success=0, error > 0: see *General error codes for Amath integration functions, type 2*).

See also: Wikipedia [1121], Takahasi and Mori [512], Ooura and M. [450], Mori [416].

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> a = 0.0; eps = 1E-8
>>> f = lambda x: ereal.Exp(-x * x / 2)
>>> result, abserr, neval, ier = ereal.Intdei(f, a, eps)
>>> print("result: ", result, "abserr: ", abserr)
>>> print("neval: ", neval, "ier: ", ier)
```

5.5.9 DE transformation, infinite interval, oscillatory factor (intdeo)

`ctx.intdeo`(*f*, *a*, *omega*, *eps*)

where `ctx` is `math53`. Performs an automatic quadrature of f(x) over (a,INF) using Double Exponential transformation when f(x) has an oscillatory factor.

Parameters

- **f** – the function for which the integral is determined.
- **a** – the left border of the integration interval.
- **omega** – oscillatory factor.
- **eps** – the relative accuracy requested.

Returns

a tuple (*integral, abserr, neval, ier*), where *integral* is an approximation to the integral, if ier=0 or 3; *abserr* is an estimate of of the modulus of the absolute error, if ier=0 or 3; *neval* is the number of integrand evaluations; and *ier* is the error code (success=0, error > 0: see *General error codes for Amath integration functions, type 2*).

See also: Wikipedia [1121], Takahasi and Mori [512], Ooura and M. [450], Mori [416].

The routine in Python:

```
# Intdeo example is missing
a = 0.0; eps = 1E-8
f = lambda x: ereal.Exp(-x * x / 2)
result, abserr, neval, ier = ereal.Intdei(f, a, eps)
print("ereal.Intdei")
print("result: ", result, "abserr: ", abserr)
print("neval: ", neval, "ier: ", ier)
return "0"
```

5.6 Boost/Math: Numerical integration

For a general overview, see: Wikipedia [1097], Wikipedia [1104].

5.6.1 Trapezoidal Quadrature

`ctxboost.Trapezoidal`(*f*, *a*, *b*, *tol*, *max_refinements*)

where `ctx` is `ctxboost`.

Parameters

- **`f`** – the function for which the integral is determined.
- **`a`** – the left border of the integration interval.
- **`b`** – the right border of the integration interval.
- **`tol`** – the requested tolerance.
- **`max_refinements`** – the maximal number of refinements. The default is 12.

Returns

a tuple (*integral, error, L1*), where *integral* is an approximation to the integral, using a trapezoidal quadrature; *error* is an estimate of the error; and *L1* is an estimate of the L1 value.

See also: BoostMath [49], Wikipedia [1122].

If we assume only that the integrand is twice continuously differentiable, we can prove that the error of the composite trapezoidal rule is O(h2). Hence halving the interval only cuts the error by about a fourth, which in turn implies that we must evaluate the function many times before an acceptable accuracy can be achieved.

However, the trapezoidal rule has an astonishing property: If the integrand is periodic, and we integrate it over a period, then the trapezoidal rule converges faster than any power of the step size h. This can be seen by examination of the Euler-Maclaurin summation formula, which relates a definite integral to its trapezoidal sum and error terms proportional to the derivatives of the function at the endpoints and the Bernoulli numbers. If the derivatives at the endpoints are the same or vanish, then the error very nearly vanishes. Hence the trapezoidal rule is essentially optimal for periodic integrands.

Other classes of integrands which are integrated efficiently by this method are the bump functions and bell-shaped integrals over the infinite interval. For details, see Trefethen's SIAM review.

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> f = lambda x: 1 / (5 - 4 * ereal.Cos(x))
>>> result2 = ereal.Trapezoidal(f, a, b)
>>> print("res: ", res)
```

```
boost.trapezoidal(f6, a, b, tol)
result:  1.3639170485190606
```

5.6.2 Gauss-Legendre quadrature

`ctxboost.GaussLegendre`(f, a, b)

where `ctx` is `ctxboost`.

Parameters

- **f** – the function for which the integral is determined.
- **a** – the left border of the integration interval.
- **b** – the right border of the integration interval.

Returns

a tuple (*integral, L1*), where *integral* is an approximation to the integral, using a non-adaptive Gauss-Legendre quadrature; and *L1* is an estimate of the L1 value.

See also: Wikipedia [1114], BoostMath [45].

This is intentionally a very simple quadrature routine, it obtains no estimate of the error, and is not adaptive, but is very efficient in simple cases that involve integrating smooth "bell like" functions and functions with rapidly convergent power series.

The Gaussian quadrature routine support both real and complex-valued quadrature.

Internally class gauss has pre-computed tables of abscissa and weights for 7, 15, 20, 25 and 30 points at up to 100-decimal digit precision. That means that using for example, gauss<double, 30>::integrate incurs absolutely zero set-up overhead from computing the abscissa/weight pairs. When using multiprecision types with less than 100 digits of precision, then there is a small initial one time cost, while the abscissa/weight pairs are constructed from strings.

However, for types with higher precision, or numbers of points other than those given above, the abscissa/weight pairs are computed when first needed and then cached for future use, which does incur a noticeable overhead.

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> a = 0.0; b = 1.0; tol = 1.0E-9
>>> f = lambda x: x * x * ereal.Atan(x)
>>> res = ereal.GaussLegendre(f, a, b)
>>> print("res: ", res)
```

```
boost.gauss_legendre(f6, a, b, tol)
result:  14.0
```

5.6.3 Gauss-Kronrod Quadrature

ctxboost.**GaussKronrod**(*f*, *a*, *b*, *max_depth*, *tol*)

where ctx is ctxboost.

Parameters

- **f** – the function for which the integral is determined.
- **a** – the left border of the integration interval.
- **b** – the right border of the integration interval.
- **max_depth** – the maximal number of levels.
- **tol** – the requested tolerance.

Returns

a tuple (*integral, error, L1*), where *integral* is an approximation to the integral, using a Gauss-Kronrod quadrature; *error* is an estimate of the error; and *L1* is an estimate of the L1 value.

See also: Wikipedia [1112], BoostMath [44].

The idea behind Gaussian quadrature is to choose n nodes and weights in such a way that polynomials of order 2n-1 are integrated exactly. However, integration of polynomials is trivial, so it is rarely done via numerical methods. Instead, transcendental and numerically defined functions are integrated via Gaussian quadrature, and the defining problem becomes how to estimate the remainder. Gaussian quadrature alone (without some form of interval splitting) cannot answer this question.

It is possible to compute a Gaussian quadrature of order n and another of order (say) 2n+1, and use the difference as an error estimate. However, this is not optimal, as the zeros of the Legendre polynomials (nodes of the Gaussian quadrature) are never the same for different orders, so 3n+1 function evaluations must be performed. Kronrod considered the problem of how to interleave nodes into a Gaussian quadrature in such a way that all previous function evaluations can be reused, while increasing the order of polynomials that can be integrated exactly. This allows an a posteriori error estimate to be provided while still preserving exponential convergence. Kronrod discovered that by adding n+1 nodes (computed from the zeros of the Legendre-Stieltjes polynomials) to a Gaussian quadrature of order n, he could integrate polynomials of order 3n+1.

The integration routines provided here will perform either adaptive or non-adaptive quadrature, they should be chosen for the integration of smooth functions with no end point singularities.

The number of points specified in the Points template parameter must be an odd number: giving a (N-1)/2 Gauss quadrature as the comparison for error estimation.

Internally class gauss_kronrod has pre-computed tables of abscissa and weights for 15, 31, 41, 51 and 61 Gauss-Kronrod points at up to 100-decimal digit precision. That means that using for example, gauss_kronrod<double, 31>::integrate incurs absolutely zero set-up overhead from computing the abscissa/weight pairs. When using multiprecision types with less than 100 digits of precision, then there is a small initial one time cost, while the abscissa/weight pairs are constructed from strings.

The Gauss-Kronrod quadrature support integrands defined on the real line and returning complex values. In this case, the template argument is the real type, and the complex type is deduced via the return type of the function.

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> a = 0.0; b = float('+inf')
>>> f = lambda x: ereal.Exp(-x * x / 2)
>>> result3 = ereal.GaussKronrod(f, a, b)
>>> print("result3: ", result3)
```

```
boost.gauss_kronrod(f6, a, b, max_depth, tol)
result:  14.000000000000002
```

5.6.4 Double-exponential quadrature: tanh_sinh

ctxboost.**TanhSinh**(*f*, *a*, *b*, *tol*, *max_refinements*)

where ctx is ctxboost.

Parameters

- **f** – the function for which the integral is determined.
- **a** – the left border of the integration interval.
- **b** – the right border of the integration interval.
- **tol** – the requested tolerance.
- **max_refinements** – the maximal number of refinements. The default is 12.

Returns

a tuple (*integral, error, L1, levels*), where *integral* is an approximation to the integral, using a tanh-sinh quadrature; *error* is an estimate of the error; *L1* is an estimate of the L1 value; and *levels* is the number of levels used.

See also: Wikipedia [1121], BoostMath [42], Okayama *et al.* [431], Okayama [432].

The tanh-sinh quadrature routine provided by boost is a rapidly convergent numerical integration scheme for holomorphic integrands. By this we mean that the integrand is the restriction to the real line of a complex-differentiable function which is bounded on the interior of the unit disk $|z| < 1$, so that it lies within the so-called Hardy space. If your integrand obeys these conditions, it can be shown that tanh-sinh integration is optimal, in the sense that it requires the fewest function evaluations for a given accuracy of any quadrature algorithm for a random element from the Hardy space.

Complex integrands are supported.

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> a = -1.0; b = 1.0
>>> f = lambda x: 5 * x + 7
>>> res = ereal.TanhSinh(f, a, b)
>>> print("res: ", res)
```

```
boost.tanh_sinh(f6, a, b)
result:  14.0
```

5.6.5 Double-exponential quadrature: sinh_sinh

`ctxboost.SinhSinh`(*f*, *tol*, *max_refinements*)

where `ctx` is `ctxboost`.

Parameters

- **f** – the function for which the integral is determined.
- **tol** – the requested tolerance.
- **max_refinements** – the maximal number of refinements. The default is 9.

Returns

a tuple (*integral, error, L1, levels*), where *integral* is an approximation to the integral, using a sinh-sinh quadrature over the limits of integration $(-\infty, \infty)$; *error* is an estimate of the error; *L1* is an estimate of the L1 value; and *levels* is the number of levels used.

See also: BoostMath [41], Okayama *et al.* [431], Okayama [432].

Returns the value of the integral of f over the limits of integration $(-\infty, \infty)$. Complex integrands are supported.

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> f = lambda x: math.exp(-x * x)
>>> res = ereal.SinhSinh(f)
>>> print("res: ", res)
```

```
boost.sinh_sinh(f7)
result:  1.7724538509055168
```

5.6.6 Double-exponential quadrature: exp_sinh

ctxboost.**ExpSinh**(*f*, *tol*, *max_refinements*, *a*, *b*)

where ctx is ctxboost.

Parameters

- **f** – the function for which the integral is determined.
- **tol** – the requested tolerance.
- **max_refinements** – the maximal number of refinements. The default is 12.
- **a** – the left border of the integration interval. The default is 0.
- **b** – the right border of the integration interval. The default is $+\infty$. Note that a and b cannot both be finite.

Returns

a tuple (*integral, error, L1, levels*), where *integral* is an approximation to the integral, using a tanh-sinh quadrature; *error* is an estimate of the error; *L1* is an estimate of the L1 value; and *levels* is the number of levels used.

Returns the value of the integral of f over the limits of integration $(0, \infty)$. Complex integrands are supported.

See also: BoostMath [40], Okayama *et al.* [431], Okayama [432].

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> f = lambda x: math.exp(-3 * x)
>>> result3 = ereal.ExpSinh(f)
>>> print("result3: ", result3)
```

```
boost.exp_sinh(f8)
result:  0.33333333333333337
```

5.6.7 Fourier Integral, Cosine

`ctxboost.OouraCos(`*f*`)`

where `ctx` is `ctxboost`.

Parameters
f – the function for which the integral is determined.

Returns
a tuple (*integral, error*), where *integral* is an approximation to the integral, using a Ooura Cos quadrature of the function f in the interval (0, +inf); *error* is an estimate of the error.

See also: BoostMath [43], Ooura and M. [451], Ooura [452].

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> f = lambda x: 1 / (x * x + 1)
>>> result3 = ereal.Ooura_Cos(f)
>>> print("result3: ", result3)
```

```
boost.OouraCos(f3, a, b, get_digits, maxit)
x0:  2.9086877250246185e-09
```

5.6.8 Fourier Integral, Sine

`ctxboost.OouraSin(`*f*`)`

where `ctx` is `ctxboost`.

Parameters
f – the function for which the integral is determined.

Returns
a tuple (*integral, error*), where *integral* is an approximation to the integral, using a Ooura Sin quadrature of the function f in the interval (0, +inf); *error* is an estimate of the error.

See also: BoostMath [43], Ooura and M. [451], Ooura [452].

The routine in Python:

```
>>> from xlcalcnet import ereal
>>> f = lambda x: 1 / x
>>> result3 = ereal.Ooura_Sin(f)
>>> print("result3: ", result3)
```

```
boost.OouraCos(f3, a, b, get_digits, maxit)
x0:  2.9086877250246185e-09
```

5.6.9 Calculating the pdf from the characteristic function

`ctx.pdf_from_cf_boost(`*x*, *cf*`)`

where `ctx` is `dec`, `mpm`, or `gmp`.

Calculates the pdf as the inverse Fourier transform of its characteristic function.

The PDF of Y is the inverse Fourier transform of its characteristic function,

$$\mathrm{pdf}_X(x) = \frac{1}{2\pi}\int_{-\infty}^{\infty} e^{ity} C_X(t)\mathrm{d}y = \frac{1}{\pi}\int_0^{\infty} \Re\left(e^{-itx} C_X(t)\right)\mathrm{d}t.$$

where $\Re(z)$ denotes the real part of z. We also have

$$\int_0^{\infty} \Re\left(e^{-itx} C_X(t)\right)\mathrm{d}t = \int_0^{\infty} \Re\left(C_X(t)\right)\cos(tx)\mathrm{d}t + \int_0^{\infty} \Im\left(C_X(t)\right)\sin(tx)\mathrm{d}t.$$

Using the right-hand side of this equation allows for efficient use of the quadrature formula of Fillon, with the half-period $\omega = \pi/x$.

5.6.10 Calculating the cdf from the characteristic function

`ctx.cdf_from_cf_continuous_boost(`*x*, *cf*`)`

where `ctx` is `dec`, `mpm`, or `gmp`.

Calculates the cdf from the characteristic function using the procedure of Gil-Pelaez.

Assuming that the characteristic function is absolutely integrable over $(-\infty, \infty)$, Gil-Pelaez derived the following inversion formula which requires integration of a real-valued function only. In particular,

$$\mathrm{cdf}_X(x) = \frac{1}{2} - \frac{1}{2\pi}\int_{-\infty}^{\infty} \frac{e^{-itx}C_X(t) - e^{itx}C_X(t)}{it}\mathrm{d}t = \frac{1}{2} - \frac{1}{\pi}\int_0^{\infty} \Im\left(\frac{e^{-itx}C_X(t)}{t}\right)\mathrm{d}t.$$

where $\Im(z)$ denotes the imaginary part of z. We also have

$$\int_0^{\infty} \Im\left(\frac{e^{-itx}C_X(t)}{t}\right)\mathrm{d}t = \int_0^{\infty} \Im\left(\frac{C_X(t)}{t}\right)\cos(tx)\mathrm{d}t - \int_0^{\infty} \Re\left(\frac{C_X(t)}{t}\right)\sin(tx)\mathrm{d}t.$$

Using the right-hand side of this equation allows for efficient use of the quadrature formula of Fillon, with the half-period $\omega = \pi/x$.

The python code is currently in Charfun.py

The following code provides a test-suite for the numerical inversion of the characteristic function:

```
class tests_charfunc(rv_cont):

    def __init__(self, rv2, x = 5, a = 0, b = 2):

        cdf_value = rv2.cdf(x)
        print ("rv2.cdf(x): ", cdf_value)

        rv2.set_x(x)
        plot(rv2.gil_pelaez_imag, [a, b], points=200)
        print

        rv2.set_x(x)
        plot(rv2.gil_pelaez_cos, [a, b], points=200)
        print

        rv2.set_x(x)
        plot(rv2.gil_pelaez_sin, [a, b], points=200)
        print

        rv2.set_x(x)
        I0 = quad(rv2.gil_pelaez_imag, [0, +inf])
        print("Integral: ", I0)
        result0 = 0.5 - I0/pi
        print("result0:", result0 )
        print("diff0:", result0 - cdf_value)

        rv2.set_x(x)
        I1 =quadosc(rv2.gil_pelaez_cos, [0, inf], period=1*pi/x) # half period
        print("I1:", I1 )

        rv2.set_x(x)
        I2 =quadosc(rv2.gil_pelaez_sin, [0, inf], period=1*pi/x) # half period
        print("I2:", I2 )

        I3 = I1 + I2
        print("I3:", I3 )
        print("Int diff:", I3 - I0)
        result3 = 0.5 - I3/pi
        print("result3:", result3 )
        print("diff3:", result3 - cdf_value)
```

Example: non-central chi-squared distribution

The following code shows the difference between using the generic integration (error: diff0: -6.1218939724378892896e-6) and quadrature for oscillatory functions (error: diff3: 8.4703294725430033907e-22).

```
mp.dps = 20
print()
print ("Hello mpDistributions local ! ")
print()

a = 0.0
b = 2

n = mpf("5")
x = mpf("10")
rv2 = mpr().chisquare(n)
```

(continues on next page)

(continued from previous page)

```
tests_charfunc(rv2, x, a, b)
```

This produces the following output (plots are to be added):

```
Hello mpDistributions local !

rv2.cdf(x):  0.92476475385348782128

Integral:  -1.334418597712864291
result0: 0.92475863195951538339
diff0: -6.1218939724378892896e-6
I1: 0.11817924829245123086
I2: -1.4526170785024453884
I3: -1.3344378302099941575
Int diff: -0.00001923249712986651l475
result3: 0.92476475385348782128
diff3: 8.4703294725430033907e-22
```

5.7 Mpmath: Numerical integration

5.7.1 General quadrature interface

`ctx.quad`(*f*, **points*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

See also: Wikipedia [1121]

See also: MathWorld [803].

Computes a single, double or triple integral over a given 1D interval, 2D rectangle, or 3D cuboid. A basic example:

```
>>> from xlcalcnet import *
>>> mp.dps = 15; mp.pretty = True
>>> quad(sin, [0, pi])
2.0
```

A basic 2D integral:

```
>>> f = lambda x, y: cos(x+y/2)
>>> quad(f, [-pi/2, pi/2], [0, pi])
4.0
```

Interval format

The integration range for each dimension may be specified using a list or tuple. Arguments are interpreted as follows:

`quad(f, [x1, x2])` – calculates $\int_{x_1}^{x_2} f(x)\,\mathrm{d}x$

`quad(f, [x1, x2], [y1, y2])` – calculates $\int_{x_1}^{x_2} \int_{y_1}^{y_2} f(x,y)\,\mathrm{d}y\,\mathrm{d}x$

`quad(f, [x1, x2], [y1, y2], [z1, z2])` – calculates $\int_{x_1}^{x_2} \int_{y_1}^{y_2} \int_{z_1}^{z_2} f(x,y,z)\,dz\,\mathrm{d}y\,\mathrm{d}x$

Endpoints may be finite or infinite. An interval descriptor may also contain more than two points. In this case, the integration is split into subintervals, between each pair of consecutive points. This is useful for dealing with mid-interval discontinuities, or integrating over large intervals where the function is irregular or oscillates.

Options

`quad()` recognizes the following keyword arguments:

method
Chooses integration algorithm (described below).

error
If set to true, `quad()` returns (v, e) where v is the integral and e is the estimated error.

maxdegree
Maximum degree of the quadrature rule to try before quitting.

verbose
Print details about progress.

Algorithms

Mpmath presently implements two integration algorithms: tanh-sinh quadrature and Gauss-Legendre quadrature. These can be selected using *method='tanh-sinh'* or *method='gauss-legendre'* or by passing the classes *method=TanhSinh*, *method=GaussLegendre*. The functions `quadts()` and `quadgl()` are also available as shortcuts.

Both algorithms have the property that doubling the number of evaluation points roughly doubles the accuracy, so both are ideal for high precision quadrature (hundreds or thousands of digits).

At high precision, computing the nodes and weights for the integration can be expensive (more expensive than computing the function values). To make repeated integrations fast, nodes are automatically cached.

The advantages of the tanh-sinh algorithm are that it tends to handle endpoint singularities well, and that the nodes are cheap to compute on the first run. For these reasons, it is used by `quad()` as the default algorithm.

Gauss-Legendre quadrature often requires fewer function evaluations, and is therefore often faster for repeated use, but the algorithm does not handle endpoint singularities as well and the nodes are more expensive to compute. Gauss-Legendre quadrature can be a better choice if the integrand is smooth and repeated integrations are required (e.g. for multiple integrals).

See the documentation for `TanhSinh` and `GaussLegendre` for additional details.

Examples of 1D integrals

Intervals may be infinite or half-infinite. The following two examples evaluate the limits of the inverse tangent function ($\int 1/(1+x^2) = \tan^{-1} x$), and the Gaussian integral $\int_{\infty}^{\infty} \exp(-x^2)\,dx = \sqrt{\pi}$:

```
>>> mp.dps = 15
>>> quad(lambda x: 2/(x**2+1), [0, inf])
3.14159265358979
>>> quad(lambda x: exp(-x**2), [-inf, inf])**2
3.14159265358979
```

Integrals can typically be resolved to high precision. The following computes 50 digits of π by integrating the area of the half-circle defined by $x^2 + y^2 \le 1$, $-1 \le x \le 1$, $y \ge 0$:

```
>>> mp.dps = 50
>>> 2*quad(lambda x: sqrt(1-x**2), [-1, 1])
3.1415926535897932384626433832795028841971693993751
```

One can just as well compute 1000 digits (output truncated):

```
>>> mp.dps = 1000
>>> 2*quad(lambda x: sqrt(1-x**2), [-1, 1])
3.14159265358979323846264338327950288419716939937...216420199
```

Complex integrals are supported. The following computes a residue at $z = 0$ by integrating counterclockwise along the diamond-shaped path from 1 to $+i$ to -1 to $-i$ to 1:

```
>>> mp.dps = 15
>>> chop(quad(lambda z: 1/z, [1,j,-1,-j,1]))
(0.0 + 6.28318530717959j)
```

Examples of 2D and 3D integrals

Here are several nice examples of analytically solvable 2D integrals (taken from MathWorld [1]) that can be evaluated to high precision fairly rapidly by `quad()`:

```
>>> mp.dps = 30
>>> f = lambda x, y: (x-1)/((1-x*y)*log(x*y))
>>> quad(f, [0, 1], [0, 1])
0.577215664901532860606512090082
>>> +euler
0.577215664901532860606512090082

>>> f = lambda x, y: 1/sqrt(1+x**2+y**2)
>>> quad(f, [-1, 1], [-1, 1])
3.17343648530607134219175646705
>>> 4*log(2+sqrt(3))-2*pi/3
3.17343648530607134219175646705

>>> f = lambda x, y: 1/(1-x**2 * y**2)
>>> quad(f, [0, 1], [0, 1])
```

(continues on next page)

(continued from previous page)

```
1.2337005501361698273543113749 8
>>> pi**2 / 8
1.2337005501361698273543113749 8

>>> quad(lambda x, y: 1/(1-x*y), [0, 1], [0, 1])
1.6449340668482264364724151666 5
>>> pi**2 / 6
1.6449340668482264364724151666 5
```

Multiple integrals may be done over infinite ranges:

```
>>> mp.dps = 15
>>> print(quad(lambda x,y: exp(-x-y), [0, inf], [1, inf]))
0.367879441171442
>>> print(1/e)
0.367879441171442
```

For nonrectangular areas, one can call `quad()` recursively. For example, we can replicate the earlier example of calculating π by integrating over the unit-circle, and actually use double quadrature to actually measure the area circle:

```
>>> f = lambda x: quad(lambda y: 1, [-sqrt(1-x**2), sqrt(1-x**2)])
>>> quad(f, [-1, 1])
3.14159265358979
```

Here is a simple triple integral:

```
>>> mp.dps = 15
>>> f = lambda x,y,z: x*y/(1+z)
>>> quad(f, [0,1], [0,1], [1,2], method='gauss-legendre')
0.101366277027041
>>> (log(3)-log(2))/4
0.101366277027041
```

Singularities

Both tanh-sinh and Gauss-Legendre quadrature are designed to integrate smooth (infinitely differentiable) functions. Neither algorithm copes well with mid-interval singularities (such as mid-interval discontinuities in $f(x)$ or $f'(x)$). The best solution is to split the integral into parts:

```
>>> mp.dps = 15
>>> quad(lambda x: abs(sin(x)), [0, 2*pi])   # Bad
3.99900894176779
>>> quad(lambda x: abs(sin(x)), [0, pi, 2*pi])  # Good
4.0
```

The tanh-sinh rule often works well for integrands having a singularity at one or both endpoints:

```
>>> mp.dps = 15
>>> quad(log, [0, 1], method='tanh-sinh')  # Good
-1.0
>>> quad(log, [0, 1], method='gauss-legendre')  # Bad
-0.999932197413801
```

However, the result may still be inaccurate for some functions:

```
>>> quad(lambda x: 1/sqrt(x), [0, 1], method='tanh-sinh')
1.99999999946942
```

This problem is not due to the quadrature rule per se, but to numerical amplification of errors in the nodes. The problem can be circumvented by temporarily increasing the precision:

```
>>> mp.dps = 30
>>> a = quad(lambda x: 1/sqrt(x), [0, 1], method='tanh-sinh')
>>> mp.dps = 15
>>> +a
2.0
```

Highly variable functions

For functions that are smooth (in the sense of being infinitely differentiable) but contain sharp mid-interval peaks or many "bumps", `quad()` may fail to provide full accuracy. For example, with default settings, `quad()` is able to integrate $\sin(x)$ accurately over an interval of length 100 but not over length 1000:

```
>>> quad(sin, [0, 100]); 1-cos(100)   # Good
0.137681127712316
0.137681127712316
>>> quad(sin, [0, 1000]); 1-cos(1000)   # Bad
-37.8587612408485
0.437620923709297
```

One solution is to break the integration into 10 intervals of length 100:

```
>>> quad(sin, linspace(0, 1000, 10))   # Good
0.437620923709297
```

Another is to increase the degree of the quadrature:

```
>>> quad(sin, [0, 1000], maxdegree=10)   # Also good
0.437620923709297
```

Whether splitting the interval or increasing the degree is more efficient differs from case to case. Another example is the function $1/(1+x^2)$, which has a sharp peak centered around $x = 0$:

```
>>> f = lambda x: 1/(1+x**2)
>>> quad(f, [-100, 100])   # Bad
3.64804647105268
>>> quad(f, [-100, 100], maxdegree=10)   # Good
3.12159332021646
>>> quad(f, [-100, 0, 100])   # Also good
3.12159332021646
```

5.7.2 Quadrature with subdivision

`ctx.quadsubdiv`(*f*, *interval*, *tol=None*, *maxintervals=None*, ***kwargs*)

where `ctx` is `mpm` or `dec`.

Computes the integral of f over the interval or path specified by interval, using quad() together with adaptive subdivision of the interval.

This function gives an accurate answer for some integrals where quad() fails:

```
>>> ctx.dps = 15; ctx.pretty = True
>>> ctx.quad(lambda x: abs(ctx.sin(x)), [0, 2*ctx.pi])
3.99900894176779
>>> ctx.quadsubdiv(lambda x: abs(ctx.sin(x)), [0, 2*ctx.pi])
4.0
>>> ctx.quadsubdiv(ctx.sin, [0, 1000])
0.437620923709297
>>> ctx.quadsubdiv(lambda x: 1/(1+x**2), [-100, 100])
3.12159332021646
>>> ctx.quadsubdiv(lambda x: ctx.ceil(x), [0, 100])
5050.0
```

(continues on next page)

(continued from previous page)

```
>>> ctx.quadsubdiv(lambda x: ctx.sin(x+ctx.exp(x)), [0,8])
0.347400172657248
```

The argument *maxintervals* can be set to limit the permissible subdivision:

```
>>> ctx.quadsubdiv(lambda x: ctx.sin(x**2), [0,100], maxintervals=5, error=True)
(-5.40487904307774, 5.011)
>>> ctx.quadsubdiv(lambda x: ctx.sin(x**2), [0,100], maxintervals=100, error=True)
(0.631417921866934, 1.10101120134116e-17)
```

Subdivision does not guarantee a correct answer, since the error estimate on subintervals may be inaccurate:

```
>>> ctx.quadsubdiv(lambda x: ctx.sech(10*x-2)**2 + ctx.sech(100*x-40)**4 \
... + ctx.sech(1000*x-600)**6, [0,1], error=True)
(0.210802735500549, 1.0001111101e-17)
>>> ctx.dps = 20
>>> ctx.quadsubdiv(lambda x: ctx.sech(10*x-2)**2 + ctx.sech(100*x-40)**4 \
... + ctx.sech(1000*x-600)**6, [0,1], error=True)
(0.21080273550054927738, 2.200000001e-24)
```

The second answer is correct. We can get an accurate result at lower precision by forcing a finer initial subdivision:

```
>>> ctx.dps = 15
>>> ctx.quadsubdiv(lambda x: ctx.sech(10*x-2)**2 + ctx.sech(100*x-40)**4 \
... + ctx.sech(1000*x-600)**6, ctx.linspace(0,1,5))
0.210802735500549
```

The following integral is too oscillatory for convergence, but we can get a reasonable estimate:

```
>>> v, err = ctx.quadsubdiv(lambda x: ctx.sin(1/x), [0,1], error=True)
>>> round(v, 6), round(err, 6)
(0.504067, 1e-06)
>>> ctx.sin(1) - ctx.ci(1)
0.504067061906928
```

5.7.3 Quadrature of oscillatory functions (Filon)

`ctx.quadosc`(*f*, *interval*, *omega=None*, *period=None*, *zeros=None*)

where `ctx` is `dec`, `mpm`, or `gmp`.

See also Filon's rule: MathWorld [802]

Calculates

$$I = \int_a^b f(x)\mathrm{d}x$$

where at least one of a and b is infinite and where $f(x) = g(x)\cos(\omega x + \phi)$ for some slowly decreasing function $g(x)$. With proper input, `quadosc()` can also handle oscillatory integrals where the oscillation rate is different from a pure sine or cosine wave.

In the standard case when $|a| < \infty, b = \infty$, `quadosc()` works by evaluating the infinite series

$$I = \int_a^{x_1} f(x)\mathrm{d}x + \sum_{k=1}^{\infty} \int_{x_k}^{x_{k+1}} f(x)\mathrm{d}x$$

where x_k are consecutive zeros (alternatively some other periodic reference point) of $f(x)$. Accordingly, `quadosc()` requires information about the zeros of $f(x)$. For a periodic function, you can specify the zeros by either providing the angular frequency ω (*omega*) or the *period* $2\pi/\omega$. In general, you can specify the n-th zero by providing the *zeros* arguments. Below is an example of each:

```
>>> from xlcalcnet import *
>>> mp.dps = 15; mp.pretty = True
>>> f = lambda x: sin(3*x)/(x**2+1)
>>> quadosc(f, [0,inf], omega=3)
0.37833007080198
>>> quadosc(f, [0,inf], period=2*pi/3)
0.37833007080198
>>> quadosc(f, [0,inf], zeros=lambda n: pi*n/3)
0.37833007080198
>>> (ei(3)*exp(-3)-exp(3)*ei(-3))/2  # Computed by Mathematica
0.37833007080198
```

Note that *zeros* was specified to multiply n by the *half-period*, not the full period. In theory, it does not matter whether each partial integral is done over a half period or a full period. However, if done over half-periods, the infinite series passed to `nsum()` becomes an *alternating series* and this typically makes the extrapolation much more efficient.

Here is an example of an integration over the entire real line, and a half-infinite integration starting at $-\infty$:

```
>>> quadosc(lambda x: cos(x)/(1+x**2), [-inf, inf], omega=1)
1.15572734979092
>>> pi/e
1.15572734979092
>>> quadosc(lambda x: cos(x)/x**2, [-inf, -1], period=2*pi)
-0.0844109505595739
>>> cos(1)+si(1)-pi/2
-0.0844109505595738
```

Of course, the integrand may contain a complex exponential just as well as a real sine or cosine:

```
>>> quadosc(lambda x: exp(3*j*x)/(1+x**2), [-inf,inf], omega=3)
(0.156410688228254 + 0.0j)
>>> pi/e**3
0.156410688228254
>>> quadosc(lambda x: exp(3*j*x)/(2+x+x**2), [-inf,inf], omega=3)
(0.00317486988463794 - 0.0447701735209082j)
>>> 2*pi/sqrt(7)/exp(3*(j+sqrt(7))/2)
(0.00317486988463794 - 0.0447701735209082j)
```

Non-periodic functions

If $f(x) = g(x)h(x)$ for some function $h(x)$ that is not strictly periodic, *omega* or *period* might not work, and it might be necessary to use *zeros*.

A notable exception can be made for Bessel functions which, though not periodic, are "asymptotically periodic" in a sufficiently strong sense that the sum extrapolation will work out:

```
>>> quadosc(j0, [0, inf], period=2*pi)
1.0
>>> quadosc(j1, [0, inf], period=2*pi)
1.0
```

More properly, one should provide the exact Bessel function zeros:

```
>>> j0zero = lambda n: findroot(j0, pi*(n-0.25))
>>> quadosc(j0, [0, inf], zeros=j0zero)
1.0
```

For an example where *zeros* becomes necessary, consider the complete Fresnel integrals

$$\int_0^\infty \cos x^2 \, dx = \int_0^\infty \sin x^2 \, dx = \sqrt{\frac{\pi}{8}}.$$

Although the integrands do not decrease in magnitude as $x \to \infty$, the integrals are convergent since the oscillation rate increases (causing consecutive periods to asymptotically cancel out). These integrals are virtually impossible to calculate to any kind of

accuracy using standard quadrature rules. However, if one provides the correct asymptotic distribution of zeros ($x_n \sim \sqrt{n}$), `quadosc()` works:

```
>>> mp.dps = 30
>>> f = lambda x: cos(x**2)
>>> quadosc(f, [0,inf], zeros=lambda n:sqrt(pi*n))
0.626657068657750125603941321203
>>> f = lambda x: sin(x**2)
>>> quadosc(f, [0,inf], zeros=lambda n:sqrt(pi*n))
0.626657068657750125603941321203
>>> sqrt(pi/8)
0.626657068657750125603941321203
```

(Interestingly, these integrals can still be evaluated if one places some other constant than π in the square root sign.)

In general, if $f(x) \sim g(x)\cos(h(x))$, the zeros follow the inverse-function distribution $h^{-1}(x)$:

```
>>> mp.dps = 15
>>> f = lambda x: sin(exp(x))
>>> quadosc(f, [1,inf], zeros=lambda n: log(n))
-0.25024394235267
>>> pi/2-si(e)
-0.250243942352671
```

Non-alternating functions

If the integrand oscillates around a positive value, without alternating signs, the extrapolation might fail. A simple trick that sometimes works is to multiply or divide the frequency by 2:

```
>>> f = lambda x: 1/x**2+sin(x)/x**4
>>> quadosc(f, [1,inf], omega=1)  # Bad
1.28642190869861
>>> quadosc(f, [1,inf], omega=0.5)  # Perfect
1.28652953559617
>>> 1+(cos(1)+ci(1)+sin(1))/6
1.28652953559617
```

Fast decay

`quadosc()` is primarily useful for slowly decaying integrands. If the integrand decreases exponentially or faster, `quad()` will likely handle it without trouble (and generally be much faster than `quadosc()`):

```
>>> quadosc(lambda x: cos(x)/exp(x), [0, inf], omega=1)
0.5
>>> quad(lambda x: cos(x)/exp(x), [0, inf])
0.5
```

5.7.4 Verified numerical integration (Okayama)

quad_verified(*f*, **points*, ***kwargs*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Computes a single integral over a given 1D interval, providing a guaranteed error bound.

This function implements an efficient algorithm for 1-dimensional numerical real integration with rigorous error bounds. See Petras [468], Petras [469] for an overview. The algorithms used in this section have been described in detail in a series of papers by Okayama *et al.* [431], Okayama [430] and Okayama [432], where explicit error bounds for the double exponential formulas proposed by Takahasi and Mori [512] are provided.

See also https://github.com/fredrik-johansson/arb/issues/196 (DH comment on integration, contains better description).

The type of integrals considered is as follows:

$$I = \int_a^b f(x)\mathrm{d}x = \int_a^b \frac{g(x)}{(x-a)^{1-\alpha}(b-x)^{1-\beta}}\mathrm{d}x, \quad \text{where}$$

$$g(x) = f(x)(x-a)^{\alpha-1}(b-x)^{\beta-1}$$

and α and β are positive constants. We assume that the integrand $f(x)$ is a function on an open interval (a, b) and may have an integrable algebraic singularity of the type shown above at the end-points $x = a$ and/or $x = b$. The function f (or the function g) needs to be analytic on the following complex domain $\mathcal{D}$:

$$\mathcal{D} = \left\{ z \in \mathbb{C} : \left| \arg\left[\frac{1}{\pi}\log\left(\frac{z-a}{b-z}\right) + \sqrt{1 + \left(\frac{1}{\pi}\log\left(\frac{z-a}{b-z}\right)\right)^2} \right] \right| < d \right\}$$

where $0 < d < \pi/2$, and satisfy, for some positive constant K, for all $z \in \mathcal{D}$ the condition

$$|f(z)| \leq\ K|z-a|^{\alpha-1}|b-z|^{\beta-1}, \quad \text{or, equivalently,}$$

$$|g(z)| \leq\ K$$

A rigorous upper bound for K, given d (which can be freely chosen observing the condition $0 < d < \pi/2$) can be computed using complex interval arithmetic; details will be discussed below.

For a given choice of d and a positive constant ϵ_{abs}, we have the following key result, which establishes an explicit rigorous bound for the absolute error of the approximation to the integral, provided that all calculations are carried out in real interval arithmetic:

$$\frac{1}{C_1}\left| \int_a^b f(x)\mathrm{d}x - h\sum_{k=-M}^{N} g(\phi(kh))P(kh) \right| \leq \epsilon_{abs}, \quad \text{where}$$

$$\phi(t) = \tanh\left(\frac{\pi}{2}\sinh(t)\right), \quad \text{and}$$

$$P(u) = \frac{\pi}{2}\left(\frac{b-a}{2}\right)^{\alpha+\beta-1}\cosh(u)(1+\phi(u))^{\alpha}(1-\phi(u))^{\beta}$$

Note that in formula ref{eq:KeyIntegrationformula} and in the subsequent formulas C_1, C_2, h, M, N only depend on d and ϵ_{abs} and the function parameters α and β. The number of intervals and the interval width h are automatically chosen in a way which balances the discretization error and the truncation error, resulting in a "nearly optimal" number of function evaluations. C_1, C_2, h, M, N are calculated as follows:

$$C_1 = \frac{2K(b-a)^{\alpha+\beta-1}}{\min(\alpha,\beta)}$$

$$C_2 = \frac{2}{\cos^{\alpha+\beta}\left(\frac{\pi}{2}\sin(d)\right)\cos(d)}$$

$$h = \frac{2\pi d}{\log\left(1+\frac{2C_2}{\epsilon_{abs}}\right)}$$

$$n = \left\lceil \frac{1}{h}\log\left(\frac{2}{\pi\min(\alpha,\beta)}\log\left(\frac{2e^{\max(\alpha,\beta)\pi/2}}{\epsilon_{abs}}\right)\right)\right\rceil$$

$$\begin{cases} M = n, & N = n - \lfloor \log(\beta/\alpha)/h \rfloor, \quad \text{for } \alpha \leq \beta \\ N = n, & M = n - \lfloor \log(\alpha/\beta)/h \rfloor, \quad \text{for } \alpha > \beta \end{cases}$$

The main challenge in implementing the algorithm is to determine a rigorous upper bound for K. We are going to achieve this by using the complex interval arithmetic which is implemented in mpmath. Since the domain $\mathcal{D}$ is not of rectangular shape, we need to compute a rectangular domain, say $\mathcal{D}_{\text{Rect}}$, which includes $\mathcal{D}$: $\mathcal{D} \subset \mathcal{D}_{\text{Rect}}$.

The rectangular domain $\mathcal{D}_{\text{Rect}}$ corresponds to a complex interval, say z_1. The function g is then evaluated in complex interval arithmetic with z_1 as argument: $z_2 = g(z_1)$. The absolute value of z_2 is a real interval, say x_1. The supremum of x_1 is a rigorous upper bound of K (see equation ref{eq:BoundFor_K_G}).

The choice of d has a great impact on $M + N + 1$, the total number of function evaluations, which are required to achieve the desired absolute error. To be able to select a near-optimal value of d resulting in the lowest number of function evaluations, we calculate n for a number of values for d, ranging from $d = 1.5$ to $d = 0.1$, using pre-computed values for the matching rectangular domains $\mathcal{D}_{\text{Rect}}$, and choose the value for d which results in the smallest n.

If equation ref{eq:gFormula} does not give a useful alternative representation of f, we set $\alpha = \beta = 1$, so that $f(x) = g(x)$. However, taking a, b, $\alpha = \frac{1}{2}$ and $\beta = 1$ let us consider the integral

$$I = \int_0^1 \frac{\sin(\exp(x))}{\sqrt{x}}\mathrm{d}x = \int_0^1 f(x)\mathrm{d}x = \int_0^1 \frac{g(x)}{\sqrt{x}}\mathrm{d}x, \text{ i.e}$$

$$f = \frac{\sin(\exp(x))}{\sqrt{x}} \text{ and } g = \sin(\exp(x))$$

In this situation, equation ref{eq:BoundFor_K_F} cannot be used to determine K because $f(z)$ has a singularity at $z = 0$; on the other hand, equation ref{eq:BoundFor_K_G} can still be used because $g(z)$ has no singularities in the interval $(0, 1)$.

It is possible to generalize this methodology to integrals for which $a = -\infty$ and/or $b = +\infty$; details can be found in Okayama (2014). Unfortunately, the resulting domains are of a shape which makes it impossible to include them in a rectangular domain, unless this domain spans the entire complex plane. Therefore, except for very few, extremely well behaved functions, the constant K cannot be determined using complex interval arithmetic (but can possibly be determined by analytical methods). The usual transformation formulas, which are widely used when performing non-verified numerical integration, are not applicable, because they will (almost always) produce a singularity at one of the endpoints, which will prevent the determination of the constant K .

5.7.5 Specialized Gauss quadrature rules

`ctx.gauss_quad_rules`(*ctx*, *n*, *qtype='legendre'*, *alpha=0*, *beta=0*)

where `ctx` is `dec`, `mpm`, or `gmp`.

This routine calulates Gaussian quadrature rules for different families of orthogonal polynomials. Let (a, b) be an interval, W(x) a positive weight function and n a positive integer.

Then the purpose of this routine is to calculate pairs (x_k, w_k) for $k = 0, 1, 2, ...(n - 1)$ which give

$$\int_a^b W(x) * F(x)\mathrm{d}x = \sum_0^{n-1} w_k * F(x_k)$$

exact for all polynomials F(x) of degree (strictly) less than 2*n. For all integrable functions F(x) the sum is (more or less) good approximation to the integral. The x_k are called nodes (which are the zeros of the related orthogonal polynomials) and the w_k are called the weights.

```
parameters
    n        (input) The degree of the quadrature rule, i.e. its number of
             nodes.

    qtype    (input) The family of orthogonal polynmomials for which to
             compute the quadrature rule. See the list below.

    alpha    (input) real number, used as parameter for some orthogonal
             polynomials
```

(continues on next page)

(continued from previous page)

```
    beta     (input) real number, used as parameter for some orthogonal
             polynomials.

return value

    (X, W)    a pair of two real arrays where x_k = X[k] and w_k = W[k].

orthogonal polynomials:

    qtype           polynomial
    -----           ----------

    "legendre"      Legendre polynomials, W(x)=1 on the interval (-1, +1)
    "legendre01"    shifted Legendre polynomials, W(x)=1 on the interval (0, +1)
    "hermite"       Hermite polynomials, W(x)=exp(-x*x) on (-infinity,+infinity)
    "laguerre"      Laguerre polynomials, W(x)=exp(-x) on (0,+infinity)
    "glaguerre"     generalized Laguerre polynomials, W(x)=exp(-x)*x**alpha on (0, +infinity)
    "chebyshev1"    Chebyshev polynomials of the first kind, W(x)=1/sqrt(1-x*x) on (-1, +1)
    "chebyshev2"    Chebyshev polynomials of the second kind, W(x)=sqrt(1-x*x) on (-1, +1)
    "jacobi"        Jacobi polynomials, W(x)=(1-x)**alpha * (1+x)**beta on (-1, +1)
                    with alpha>-1 and beta>-1

Gauss-Chebyshev quadrature, first and second kind

See also: MathWorld [807], Wikipedia [1113], Gatteschi [344], Petras [468], Petras [469].

See also: https://en.wikipedia.org/wiki/Chebyshev%E2%80%93Gauss_quadrature

See also: https://mathworld.wolfram.com/Chebyshev-GaussQuadrature.html

See also: Abramowitz, p. 383

For the first kind:

$$\int_{-1}^{1} \frac{f(x)}{\sqrt{1-x^2}}\mathrm{d}x = \sum_{i=1}^{n} w_i f(x_i) + R_n, \quad \text{where}$$

$$x_i = \cos\left(\frac{2i-1}{2n}\pi\right), w_i = \frac{\pi}{n}, \quad R_n = \frac{f^{(2n)}(\xi)\pi}{(2n)!2^{2n-1}} \text{ for } -1 < \xi < 1.$$

For the second kind:

$$\int_{-1}^{1} \sqrt{1-x^2} g(x)\mathrm{d}x = \sum_{i=1}^{n} w_i g(x_i) + R_n, \quad \text{where}$$

$$x_i = \cos\left(\frac{i}{n+1}\pi\right), w_i = \frac{\pi}{n+1}\sin^2\left(\frac{i}{n+1}\pi\right), \quad R_n = \frac{g^{(2n)}(\xi)\pi}{(2n)!2^{2n+1}} \text{ for } -1 < \xi < 1.$$

```
def demo_gauss_quadrature_chebyshev(ctx):
    # orthogonality of the chebyshev polynomials:
    f = lambda x: ctx.chebyt(3, x) * ctx.chebyt(2, x) # problem with gpm.chebyt
```

(continues on next page)

(continued from previous page)

```
    X, W = gauss_quadrature(ctx, 3, "chebyshev1")
    A = ctx.fdot([(f(x), w) for x, w in zip(X, W)])
    print("A:", A)
    print(ctx.chop(A, tol = 1e-10))
```

Gauss-Legendre quadrature

See also: MathWorld [808], Wikipedia [1114], Petras [468], Petras [469].

$$\int_a^b f(x)\mathrm{d}x = \frac{b-a}{2}\sum_{i=1}^{n} w_i f\left(\tfrac{1}{2}(b-a)(x_i+1)\right) + R_n, \quad \text{where}$$

$$w_i = \frac{2}{((1-x^2)P_n'(x_i))^2}, \quad R_n = \frac{f^{(2n)}(\xi)(b-a)^{2n+1}(n!)^4}{((2n+1)(2n)!)^3} \text{ for } a < \xi < b,$$

P_n are the Legendre polynomials of degree n, and x_i is the i^{th} zero of P_n.

```
def demo_gauss_quadrature_laguerre_mp():
    from xlcalcnet.mpmath import mp
    f = lambda x: x**5 - 2 * x**4 + 3 * x**3 - 5 * x**2 + 7 * x - 11
    X, W = mp.gauss_quadrature(3, "laguerre")
    A = mp.fdot([(f(x), w) for x, w in zip(X, W)])
    B = 76
    C = mp.quad(lambda x: mp.exp(-x) * f(x), [0, +mp.inf])
    print("A:", A)
    print("B:", B)
    print("C:", C)
    print(mp.chop(A-B, tol = 1e-10), mp.chop(A-C, tol = 1e-10))
```

Gauss-Jacobi quadrature

See also: MathWorld [806], Wikipedia [1111], Petras [468], Petras [469].

$$\int_a^b f(x)(1-x)^\alpha(1+x)^\beta\mathrm{d}x = \frac{b-a}{2}\sum_{i=1}^{n} w_i f\left(\tfrac{1}{2}(b-a)(x_i+1)\right) + R_n, \quad \text{where } \alpha,\beta > -1,$$

$$w_i = -\frac{2n+\alpha+\beta+2}{n+\alpha+\beta+1}\frac{\Gamma(n+\alpha+1)\Gamma(n+\beta+1)}{\Gamma(n+\alpha+\beta+1)(n+1)!}\frac{2^{\alpha+\beta}}{P_n^{(\alpha,\beta)\prime}(x_i)P_{n+1}^{(\alpha,\beta)}(x_i)},$$

$$R_n = \frac{\Gamma(n+\alpha+1)\Gamma(n+\beta+1)\Gamma(n+\alpha+\beta+1)}{(2n+\alpha+\beta+1)[\Gamma(2n+\alpha+\beta+1)]^2}\frac{2^{2+\alpha+\beta+1}}{(2n)!}f^{(2n)}(\xi), \text{ for } a < \xi < b,$$

$P_n^{(\alpha,\beta)}$ are the Jacobi polynomials of degree n, and x_i is the i^{th} zero of $P_n^{(\alpha,\beta)}$.

Gauss-Legendre quadrature is a special case of Gauss-Jacobi quadrature with $\alpha = \beta = 0$. Similarly, the Chebyshev-Gauss quadrature of the first (second) kind arises when one takes $\alpha = \beta = -0.5(+0.5)$. The special case $\alpha = \beta$ turns Jacobi polynomials into Gegenbauer polynomials, in which case the technique is sometimes called Gauss-Gegenbauer quadrature. Gauss-Jacobi quadrature can be used to approximate integrals with singularities at the end points.

```
def demo_gauss_quadrature_laguerre_mp():
    from xlcalcnet.mpmath import mp
    f = lambda x: x**5 - 2 * x**4 + 3 * x**3 - 5 * x**2 + 7 * x - 11
    X, W = mp.gauss_quadrature(3, "laguerre")
    A = mp.fdot([(f(x), w) for x, w in zip(X, W)])
    B = 76
    C = mp.quad(lambda x: mp.exp(-x) * f(x), [0, +mp.inf])
    print("A:", A)
    print("B:", B)
    print("C:", C)
    print(mp.chop(A-B, tol = 1e-10), mp.chop(A-C, tol = 1e-10))
```

Gauss-Laguerre quadrature, classic and generalized

See also: MathWorld [807], Wikipedia [1113], Gatteschi [344], Petras [468], Petras [469].

$$\int_0^\infty e^{-ax} f(x)\mathrm{d}x = \frac{1}{a}\sum_{i=1}^{n} w_i f\left(\frac{x_i}{a}\right) + R_n, \quad \text{where}$$

$$w_i = \frac{x_i}{((n+1)L_{n+1}(x_i))^2}, \quad R_n = \frac{f^{(2n)}(\xi)(n!)^2}{(2n)!} \text{ for } 0 < \xi < \infty,$$

L_n are the Laguerre polynomials of degree n, and x_i is the i^{th} zero of L_n.

```
def demo_gauss_quadrature_laguerre_mp():

```

5.8 Mpmath: Numerical inverse Laplace transform

5.8.1 General inverse Laplace transform interface

`ctx.invertlaplace`(*f*, *t*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

See also: Cohen [181], Duffy [291], Bellman *et al.* [28], Davies and Martin [201], Duffy [290], Kuhlman [400].

Computes the numerical inverse Laplace transform for a Laplace-space function at a given time. The function being evaluated is assumed to be a real-valued function of time.

The user must supply a Laplace-space function $\bar{f}(p)$, and a desired time at which to estimate the time-domain solution $f(t)$.

Options

`invertlaplace()` recognizes the following optional keywords valid for all methods:

method
Chooses numerical inverse Laplace transform algorithm (described below).

degree
Number of terms used in the approximation

Basic examples

A few basic examples of Laplace-space functions with known inverses (see Abate and Valko [1], Talbot [513]) :

$$\mathcal{L}\left\{f(t)\right\} = \bar{f}(p)$$

$$\mathcal{L}^{-1}\left\{\bar{f}(p)\right\} = f(t)$$

$$\bar{f}(p) = \frac{1}{(p+1)^2}$$

$$f(t) = te^{-t}$$

```
>>> from xlcalcnet import *
>>> mp.dps = 15; mp.pretty = True
>>> tt = [0.001, 0.01, 0.1, 1, 10]
>>> fp = lambda p: 1/(p+1)**2
>>> ft = lambda t: t*exp(-t)
>>> ft(tt[0]),ft(tt[0])-invertlaplace(fp,tt[0],method='talbot')
(0.000999000499833375, 8.57923043561212e-20)
>>> ft(tt[1]),ft(tt[1])-invertlaplace(fp,tt[1],method='talbot')
(0.00990049833749168, 3.27007646698047e-19)
>>> ft(tt[2]),ft(tt[2])-invertlaplace(fp,tt[2],method='talbot')
(0.090483741803596, -1.75215800052168e-18)
>>> ft(tt[3]),ft(tt[3])-invertlaplace(fp,tt[3],method='talbot')
(0.367879441171442, 1.2428864009344e-17)
>>> ft(tt[4]),ft(tt[4])-invertlaplace(fp,tt[4],method='talbot')
(0.000453999297624849, 4.04513489306658e-20)
```

The methods also work for higher precision:

```
>>> mp.dps = 100; mp.pretty = True
>>> nstr(ft(tt[0]),15),nstr(ft(tt[0])-invertlaplace(fp,tt[0],method='talbot'),15)
('0.000999000499833375', '-4.96868310693356e-105')
>>> nstr(ft(tt[1]),15),nstr(ft(tt[1])-invertlaplace(fp,tt[1],method='talbot'),15)
('0.00990049833749168', '1.23032291513122e-104')
```

$$\bar{f}(p) = \frac{1}{p^2+1}$$

$$f(t) = \mathrm{J}_0(t)$$

```
>>> mp.dps = 15; mp.pretty = True
>>> fp = lambda p: 1/sqrt(p*p + 1)
>>> ft = lambda t: besselj(0,t)
>>> ft(tt[0]),ft(tt[0])-invertlaplace(fp,tt[0])
(0.999999750000016, -8.2477943034014e-18)
>>> ft(tt[1]),ft(tt[1])-invertlaplace(fp,tt[1])
(0.99997500015625, -3.69810144898872e-17)
```

$$\bar{f}(p) = \frac{\log p}{p}$$

$$f(t) = -\gamma - \log t$$

```
>>> mp.dps = 15; mp.pretty = True
>>> fp = lambda p: log(p)/p
>>> ft = lambda t: -euler-log(t)
>>> ft(tt[0]),ft(tt[0])-invertlaplace(fp,tt[0],method='stehfest')
(6.3305396140806, -1.92126634837863e-16)
>>> ft(tt[1]),ft(tt[1])-invertlaplace(fp,tt[1],method='stehfest')
(4.02795452108656, -4.81486093200704e-16)
```

Relationship to distribution functions

The concept of Laplace transforms also finds use in the context of statistical distribution functions, although here often the moment generating function $M_X(t)$ is given instead of the Laplace transform $\mathcal{L}\{f(t)\}$. They are related by $\mathcal{L}\{f(t)\} = M_X(-t)$. Note that in the case of statistical distribution functions, neither $M_X(t)$ nor $\mathcal{L}\{f(t)\}$ are guaranteed to exist. If they do, however, they can be used to calculate the pdf and cdf, particularly if the domain of X is $X > 0$.

The Laplace transform (of the pdf)of a nonnegative RV uniquely determines the distribution. Applying the inverse Laplace transform to the Laplace transform of the distribution gives the pdf.

These two transformations, $X \longrightarrow e^{-sX}$ provides the definition of a Laplace transformation:

$$\mathcal{L}[f](s) := \mathrm{E}^{\mathbb{P}}\left[e^{-sX}\right] = \int_{\mathbb{R}} e^{-sx} f_X(x)\mathrm{d}x.$$

Therefore, given a (nonnegative) random variable X and its associated probability density (PDF) $f_X(x)$, we always have the Laplace transform of that density $\mathcal{L}[f_X](s)$ defined at s . But note that this also requires a transformation of the parameter x in to $-s$.

The Laplace transform finds the CDF in the transformed variable s easily:

$$F_X(x) = \mathcal{L}^{-1}\left[\frac{1}{s}\,\mathrm{E}^{\mathbb{P}}\left[e^{-sX}\right]\right](x).$$

Singularities

All numerical inverse Laplace transform methods have problems at large time when the Laplace-space function has poles, singularities, or branch cuts to the right of the origin in the complex plane. For simple poles in $\bar{f}(p)$ at the p-plane origin, the time function is constant in time (e.g., $\mathcal{L}\{1\} = 1/p$ has a pole at $p = 0$). A pole in $\bar{f}(p)$ to the left of the origin is a decreasing function of time (e.g., $\mathcal{L}\left\{e^{-t/2}\right\} = 1/(p + 1/2)$ has a pole at $p = -1/2$), and a pole to the right of the origin leads to an increasing function in time (e.g., $\mathcal{L}\left\{te^{t/4}\right\} = 1/(p - 1/4)^2$ has a pole at $p = 1/4$). When singularities occur off the real p axis, the time-domain function is oscillatory. For example $\mathcal{L}\{\mathrm{J}_0(t)\} = 1/\sqrt{p^2 + 1}$ has a branch cut starting at $p = j = \sqrt{-1}$ and is a decaying oscillatory function, This range of behaviors is illustrated in Duffy [3] Figure 4.10.4, p. 228.

In general as $p \to \infty$ $t \to 0$ and vice-versa. All numerical inverse Laplace transform methods require their abscissa to shift closer to the origin for larger times. If the abscissa shift left of the rightmost singularity in the Laplace domain, the answer will be completely wrong (the effect of singularities to the right of the Bromwich contour are not included in the results).

For example, the following exponentially growing function has a pole at $p = 3$:

$$\bar{f}(p) = \frac{1}{p^2 - 9}$$

$$f(t) = \frac{1}{3}\sinh 3t$$

```
>>> mp.dps = 15; mp.pretty = True
>>> fp = lambda p: 1/(p*p-9)
>>> ft = lambda t: sinh(3*t)/3
>>> tt = [0.01,0.1,1.0,10.0]
>>> ft(tt[0]),invertlaplace(fp,tt[0],method='talbot')
(0.0100015000675014, 0.0100015000675014)
>>> ft(tt[1]),invertlaplace(fp,tt[1],method='talbot')
(0.101506764482381, 0.101506764482381)
>>> ft(tt[2]),invertlaplace(fp,tt[2],method='talbot')
(3.33929164246997, 3.33929164246997)
>>> ft(tt[3]),invertlaplace(fp,tt[3],method='talbot')
(1781079096920.74, -1.61331069624091e-14)
```

Algorithms

Mpmath implements three numerical inverse Laplace transform algorithms, attributed to: Talbot, Stehfest, and de Hoog, Knight and Stokes. These can be selected by using *method='talbot'*, *method='stehfest'*, *method='dehoog'*, or *method='cohen'* The functions `mpmath.invlaptalbot`, `mpmath.invlapstehfest`, and `mpmath.invlapdehoog` and `mpmath.invlapcohen` are also available as shortcuts.

All four algorithms implement a heuristic balance between the requested precision and the precision used internally for the calculations. This has been tuned for a typical exponentially decaying function and precision up to few hundred decimal digits.

The Laplace transform converts the variable time (i.e., along a line) into a parameter given by the right half of the complex p-plane. Singularities, poles, and branch cuts in the complex p-plane contain all the information regarding the time behavior of the corresponding function. Any numerical method must therefore sample p-plane "close enough" to the singularities to accurately characterize them, while not getting too close to have catastrophic cancellation, overflow, or underflow issues. Most significantly, if one or more of the singularities in the p-plane is not on the left side of the Bromwich contour, its effects will be left out of the computed solution, and the answer will be completely wrong.

5.8.2 Talbot method

`ctx.`**`invlaptalbot`**(*f*, *t*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

See also: Abate and Valko [1], Talbot [513].

The fixed Talbot method is high accuracy and fast, but the method can catastrophically fail for certain classes of time-domain behavior, including a Heaviside step function for positive time (e.g., $H(t-2)$), or some oscillatory behaviors. The Talbot method usually has adjustable parameters, but the "fixed" variety implemented here does not. This method deforms the Bromwich integral contour in the shape of a parabola towards $-\infty$, which leads to problems when the solution has a decaying exponential in it (e.g., a Heaviside step function is equivalent to multiplying by a decaying exponential in Laplace space).

`def calc_laplace_parameter(self,t,**kwargs)`

The "fixed" Talbot method deforms the Bromwich contour towards $-\infty$ in the shape of a parabola. Traditionally the Talbot algorithm has adjustable parameters, but the "fixed" version does not. The r parameter could be passed in as a parameter, if you want to override the default given by (Abate & Valko, 2004).

The Laplace parameter is sampled along a parabola opening along the negative imaginary axis, with the base of the parabola along the real axis at $p = \frac{r}{t_{\max}}$. As the number of terms used in the approximation (degree) grows, the abscissa required for function evaluation tend towards $-\infty$, requiring high precision to prevent overflow. If any poles, branch cuts or other singularities exist such that the deformed Bromwich contour lies to the left of the singularity, the method will fail.

Optional arguments

`calc_laplace_parameter` recognizes the following keywords

tmax
: maximum time associated with vector of times (typically just the time requested)

degree
integer order of approximation (M = number of terms)

r
abscissa for p_0 (otherwise computed using rule of thumb $2M/5$)

The working precision will be increased according to a rule of thumb. If 'degree' is not specified, the working precision and degree are chosen to hopefully achieve the dps of the calling context. If 'degree' is specified, the working precision is chosen to achieve maximum resulting precision for the specified degree.

$$p_0 = \frac{r}{t}$$

$$p_i = \frac{ir\pi}{Mt_{\max}}\left[\cot\left(\frac{i\pi}{M}\right) + j\right] \qquad 1 \le i < M$$

where $j = \sqrt{-1}$, $r = 2M/5$, and $t_{\max}$ is the maximum specified time.

`def calc_time_domain_solution(self,fp,t,manual_prec=False)`

The fixed Talbot time-domain solution is computed from the Laplace-space function evaluations using

$$f(t, M) = \frac{2}{5t}\sum_{k=0}^{M-1} \Re\left[\gamma_k \bar{f}(p_k)\right]$$

where

$$\gamma_0 = \frac{1}{2}e^r \bar{f}(p_0)$$

$$\gamma_k = e^{tp_k}\left\{1 + \frac{jk\pi}{M}\left[1 + \cot\left(\frac{k\pi}{M}\right)^2\right] - j\cot\left(\frac{k\pi}{M}\right)\right\} \qquad 1 \le k < M.$$

Again, $j = \sqrt{-1}$.

Before calling this function, call `calc_laplace_parameter` to set the parameters and compute the required coefficients.

5.8.3 Stehfest method

`ctx.invlapstehfest(`*f*, *t*, ***kwargs*`)`

where `ctx` is `dec`, `mpm`, or `gmp`.

See also: Stehfest [506], Widder [1082].

The Stehfest algorithm only uses abscissa along the real axis of the complex p-plane to estimate the time-domain function. Oscillatory time-domain functions have poles away from the real axis, so this method does not work well with oscillatory functions, especially high-frequency ones. This method also depends on summation of terms in a series that grows very large, and will have catastrophic cancellation during summation if the working precision is too low.

`def calc_laplace_parameter(self,t,**kwargs)`

The Gaver-Stehfest method is a discrete approximation of the Widder-Post inversion algorithm, rather than a direct approximation of the Bromwich contour integral.

The method abscissa along the real axis, and therefore has issues inverting oscillatory functions (which have poles in pairs away from the real axis).

The working precision will be increased according to a rule of thumb. If 'degree' is not specified, the working precision and degree are chosen to hopefully achieve the dps of the calling context. If 'degree' is specified, the working precision is chosen to achieve maximum resulting precision for the specified degree.

$$p_k = \frac{k\log 2}{t} \qquad 1 \le k \le M$$

`def calc_time_domain_solution(self,fp,t,manual_prec=False)`

Compute time-domain Stehfest algorithm solution.

$$f(t,M) = \frac{\log 2}{t} \sum_{k=1}^{M} V_k \bar{f}\left(p_k\right)$$

where

$$V_k = (-1)^{k+N/2} \sum_{i=\lfloor (k+1)/2 \rfloor}^{\min(k,N/2)} \frac{i^{\frac{N}{2}}(2i)!}{\left(\frac{N}{2}-i\right)!\, i!\, (i-1)!\, (k-i)!\, (2i-k)!}$$

As the degree increases, the abscissa (p_k) only increase linearly towards ∞, but the Stehfest coefficients (V_k) alternate in sign and increase rapidly in sign, requiring high precision to prevent overflow or loss of significance when evaluating the sum.

5.8.4 de Hoog, Knight, and Stokes method

`ctx.invlapdehoog`(f, t, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

See also: Davies [200], [deHoog1982`.

The de Hoog, Knight, and Stokes method is essentially a Fourier-series quadrature-type approximation to the Bromwich contour integral, with non-linear series acceleration and an analytical expression for the remainder term. This method is typically the most robust and is therefore the default method. This method also involves the greatest amount of overhead, so it is typically the slowest of the three methods at high precision.

`calc_laplace_parameter(self,t,**kwargs)`

The de Hoog, Knight & Stokes algorithm is an accelerated form of the Fourier series numerical inverse Laplace transform algorithms.

$$p_k = \gamma + \frac{jk}{T} \qquad 0 \le k < 2M+1$$

where

$$\gamma = \alpha - \frac{\log \mathrm{tol}}{2T},$$

$j = \sqrt{-1}$, $T = 2t_{\max}$ is a scaled time, $\alpha = 10^{-\mathrm{dps_goal}}$ is the real part of the rightmost pole or singularity, which is chosen based on the desired accuracy (assuming the rightmost singularity is 0), and $\mathrm{tol} = 10\alpha$ is the desired tolerance, which is chosen in relation to α.`

When increasing the degree, the abscissa increase towards $j\infty$, but more slowly than the fixed Talbot algorithm. The de Hoog et al. algorithm typically does better with oscillatory functions of time, and less well-behaved functions. The method tends to be slower than the Talbot and Stehfest algorithsm, especially so at very high precision (e.g., > 500 digits precision).

`def calc_time_domain_solution(self,fp,t,manual_prec=False)` Calculate time-domain solution for de Hoog, Knight & Stokes algorithm.

The un-accelerated Fourier series approach is:

$$f(t,2M+1) = \frac{e^{\gamma t}}{T} \sum_{k=0}^{2M}{}' \Re\left[\bar{f}\left(p_k\right) e^{i\pi t/T}\right],$$

where the prime on the summation indicates the first term is halved.

This simplistic approach requires so many function evaluations that it is not practical. Non-linear acceleration is accomplished via Pade-approximation and an analytic expression for the remainder of the continued fraction. See the original paper (reference 2 below) a detailed description of the numerical approach.

5.8.5 Cohen method

`ctx.invlapcohen`(*f*, *t*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

See also Cohen *et al.* [182], Glasserman and Ruiz-Mata [350].

The Cohen method is a trapezoidal rule approximation to the Bromwich contour integral, with linear acceleration for alternating series. This method is as robust as the de Hoog et al method and the fastest of the four methods at high precision, and is therefore the default method.

The Cohen algorithm accelerates the convergence of the nearly alternating series resulting from the application of the trapezoidal rule to the Bromwich contour inversion integral.

$$p_k = \frac{\gamma}{2t} + \frac{\pi i k}{t} \qquad 0 \le k < M$$

where

$$\gamma = \frac{2}{3}(d + \log(10) + \log(2t)),$$

$d = \mathrm{dps_goal}$, which is chosen based on the desired accuracy using the method developed in [1] to improve numerical stability. The Cohen algorithm shows robustness similar to the de Hoog et al. algorithm, but it is faster than the fixed Talbot algorithm.

Optional arguments

degree
: integer order of the approximation (M = number of terms)

alpha
: abscissa for p_0 (controls the discretization error)

The working precision will be increased according to a rule of thumb. If 'degree' is not specified, the working precision and degree are chosen to hopefully achieve the dps of the calling context. If 'degree' is specified, the working precision is chosen to achieve maximum resulting precision for the specified degree.

Calculate time-domain solution for Cohen algorithm.

The accelerated nearly alternating series is:

$$f(t, M) = \frac{e^{\gamma/2}}{t}\left[\frac{1}{2}\Re\left(\bar{f}\left(\frac{\gamma}{2t}\right)\right) - \sum_{k=0}^{M-1}\frac{c_{M,k}}{d_M}\Re\left(\bar{f}\left(\frac{\gamma + 2(k+1)\pi i}{2t}\right)\right)\right],$$

where coefficients $\frac{c_{M,k}}{d_M}$ are described in Cohen *et al.* [182].

5.9 Boost/Odeint: Ordinary differential equations

Boost Odeint is a library for solving initial value problems (IVP) of ordinary differential equations. Mathematically, these problems are formulated as follows:

$$x'(t) = f(x,t), x(0) = x0.$$

x and f can be vectors and the solution is some function x(t) fulfilling both equations above. In the following we will refer to x'(t) also dxdt which is also our notation for the derivative in the source code.

Ordinary differential equations occur nearly everywhere in natural sciences. For example, the whole Newtonian mechanics are described by second order differential equations. Be sure, you will find them in every discipline. They also occur if partial differential equations (PDEs) are discretized. Then, a system of coupled ordinary differential occurs, sometimes also referred as lattices ODEs.

odeint provides a quite large number of different steppers such that the user is left with the question of which stepper fits his needs. Our personal recommendations are:

runge_kutta_dopri5 is maybe the best default stepper. It has step size control as well as dense-output functionality. Simple create a dense-output stepper by make_dense_output(1.0e-6 , 1.0e-5 , runge_kutta_dopri5< state_type >()).

runge_kutta4 is a good stepper for constant step sizes. It is widely used and very well known. If you need to create artificial time series this stepper should be the first choice.

'runge_kutta_fehlberg78' is similar to the 'runge_kutta4' with the advantage that it has higher precision. It can also be used with step size control.

adams_bashforth_moulton is very well suited for ODEs where the r.h.s. is expensive (in terms of computation time). It will calculate the system function only once during each step.

See also: BoostMath [5], Wikipedia [1115].

5.9.1 Runge-Kutta 4 method, constant stepper

ctxboost.**RungeKutta4Const**(*F1*, *F2*, *matInput*, *StartTime*, *EndTime*, *mathrm{d}t*)

Solves Ordinary differential equations using the Runge-Kutta 4 method with a constant stepper.

See also: Wikipedia [1117], Rump [495], Kutta [403].

In numerical analysis, the Runge-Kutta methods are an important family of implicit and explicit iterative methods, which are used in temporal discretization for the approximation of solutions of ordinary differential equations. These techniques were developed around 1900 by the German mathematicians C. Runge and M. W. Kutta.

See the article on numerical methods for ordinary differential equations for more background and other methods. See also List of Runge-Kutta methods.

One member of the family of Runge-Kutta methods is often referred to as "RK4", "classical Runge-Kutta method" or simply as "the Runge-Kutta method".

Let an initial value problem be specified as follows.

Here, y is an unknown function (scalar or vector) of time t which we would like to approximate; we are told that , the rate at which y changes, is a function of t and of y itself. At the initial time the corresponding y-value is . The function f and the data , are given.

Example:

```
Public Sub matLorenz(x As dbl_mat_t, dxdt As dbl_mat_t)
    Dim sigma, R, b As Double
    sigma = 10: R = 28: b = 8 / 3
    dxdt(0) = sigma * ( x(1) - x(0) )
    dxdt(1) = R * x(0) - x(1) - x(0) * x(2)
    dxdt(2) = -b * x(2) + x(0) * x(1)
End Sub

Sub DemoLorenzOdeintLocal()
    Console.WriteLine( "DemoLorenzOdeintLocal(matX, StartTime, EndTime, \mathrm{d}t)")
    Dim matX3 As New dbl_mat_t()
    matX3.resize(3,1)
    matX3(0) = 10.0
    matX3(1) = 10.0
    matX3(2) = 10.0
    Dim StartTime = 0.0
    Dim EndTime = 10.0
    Dim \mathrm{d}t = 0.1
    matX3.print("matX at StartTime", 15)
    Dim ODE As New Odeint(AddressOf matLorenz, matX3, StartTime, EndTime, \mathrm{d}t)
    ODE.Integrate()
    matX3.print("matX at EndTime", 15)
End Sub
```

This produces the following output:

```
DemoLorenzOdeintLocal(matX, StartTime, EndTime, \mathrm{d}t)
matX at StartTime
10,
10,
10,

matX at EndTime
-2.43203453419697,
0.560815431795122,
25.4697563106702,
```

5.9.2 Cash-Karp method, constant stepper

ctxboost.**CashKarpConst**(*F1*, *F2*, *matInput*, *StartTime*, *EndTime*, \mathrm{d}t)

Solves Ordinary differential equations using the Cash-Karp method, using a constant stepper

See also: Wikipedia [1106], Cash and Karp [174].

In numerical analysis, the Cash-Karp method is a method for solving ordinary differential equations (ODEs). It was proposed by Professor Jeff R. Cash [1] from Imperial College London and Alan H. Karp from IBM Scientific Center. The method is a member of the Runge-Kutta family of ODE solvers. More specifically, it uses six function evaluations to calculate fourth- and fifth-order accurate solutions. The difference between these solutions is then taken to be the error of the (fourth order) solution. This error estimate is very convenient for adaptive stepsize integration algorithms. Other similar integration methods are Fehlberg (RKF) and Dormand-Prince (RKDP).

5.9.3 Dormand-Prince 5 method, constant stepper

ctxboost.**DormandPrince5Const**(*F1*, *F2*, *matInput*, *StartTime*, *EndTime*, \mathrm{d}t, *epsabs*, *epsrel*)

Solves Ordinary differential equations using the Dormand-Prince method, using a constant stepper

See also: Wikipedia [1108], Dormand and Prince [287].

In numerical analysis, the Dormand-Prince method, or DOPRI method, is an explicit method for solving ordinary differential equations citep{Dormand1980}. The method is a member of the Runge-Kutta family of ODE solvers. More specifically, it uses six function evaluations to calculate fourth- and fifth-order accurate solutions. The difference between these solutions is then taken to be the error of the (fourth-order) solution. This error estimate is very convenient for adaptive stepsize integration algorithms. Other similar integration methods are Fehlberg (RKF) and Cash-Karp (RKCK).

The Dormand-Prince method has seven stages, but it uses only six function evaluations per step because it has the FSAL (First Same As Last) property: the last stage is evaluated at the same point as the first stage of the next step. Dormand and Prince choose the coefficients of their method to minimize the error of the fifth-order solution. This is the main difference with the Fehlberg method, which was constructed so that the fourth-order solution has a small error. For this reason, the Dormand-Prince method is more suitable when the higher-order solution is used to continue the integration, a practice known as local extrapolation (Shampine 1986; Hairer, Nørsett & Wanner 2008, pp. 178-179).

5.9.4 Fehlberg 78 method, constant stepper

ctxboost.**Fehlberg78Const**(*F1*, *F2*, *matInput*, *StartTime*, *EndTime*, *mathrm{d}t*, *epsabs*, *epsrel*)

Solves Ordinary differential equations using the Fehlberg 78 method, using a constant stepper

See also: Wikipedia [1118], Fehlberg [299].

In mathematics, the Runge-Kutta-Fehlberg method (or Fehlberg method) is an algorithm in numerical analysis for the numerical solution of ordinary differential equations. It was developed by the German mathematician Erwin Fehlberg and is based on the large class of Runge-Kutta methods.

The novelty of Fehlberg's method is that it is an embedded method from the Runge-Kutta family, meaning that identical function evaluations are used in conjunction with each other to create methods of varying order and similar error constants. The method presented in Fehlberg's 1969 paper has been dubbed the RKF45 method, and is a method of order O(h4) with an error estimator of order O(h5).[1] By performing one extra calculation, the error in the solution can be estimated and controlled by using the higher-order embedded method that allows for an adaptive stepsize to be determined automatically.

5.9.5 Adams-Bashforth-Moulton, constant stepper

ctxboost.**AdamsBashforthMoultonConst**(*F1*, *F2*, *matInput*, *StartTime*, *EndTime*, \mathrm{d}t, *epsabs*, *epsrel*)

Solves Ordinary differential equations using the Adams-Bashforth-Moulton method, using a constant stepper

See also: Wikipedia [1109].

The methods of Euler, Heun, Taylor and Runge-Kutta are called single-step methods because they use only the information from one previous point to compute the successive point, that is, only the initial point is used to compute and in general is needed to compute . After several points have been found it is feasible to use several prior points in the calculation. The Adams-Bashforth-Moulton method uses in the calculation of . This method is not self-starting; four initial points , , , and must be given in advance in order to generate the points .

A desirable feature of a multistep method is that the local truncation error (L. T. E.) can be determined and a correction term can be included, which improves the accuracy of the answer at each step. Also, it is possible to determine if the step size is small enough to obtain an accurate value for , yet large enough so that unnecessary and time-consuming calculations are eliminated. If the code for the subroutine is fine-tuned, then the combination of a predictor and corrector requires only two function evaluations of f(t,y) per step.

5.9.6 Cash-Karp method, adaptive stepper

ctxboost.**CashKarpAdaptive**(*F1*, *F2*, *matInput*, *StartTime*, *EndTime*, \mathrm{d}t, *epsabs*, *epsrel*)

Solves Ordinary differential equations using the Cash-Karp method method with an adaptive stepper.

See also: Wikipedia [1106], Cash and Karp [174].

In numerical analysis, the Cash-Karp method is a method for solving ordinary differential equations (ODEs). It was proposed by Professor Jeff R. Cash [1] from Imperial College London and Alan H. Karp from IBM Scientific Center. The method is a member of the Runge-Kutta family of ODE solvers. More specifically, it uses six function evaluations to calculate fourth- and fifth-order accurate solutions. The difference between these solutions is then taken to be the error of the (fourth order) solution. This error estimate is very convenient for adaptive stepsize integration algorithms. Other similar integration methods are Fehlberg (RKF) and Dormand-Prince (RKDP).

5.9.7 Dormand-Prince 5 method, adaptive stepper

ctxboost.**DormandPrince5Adaptive**(*F1*, *F2*, *matInput*, *StartTime*, *EndTime*, *mathrm{d}t*, *epsabs*, *epsrel*)

Solves Ordinary differential equations using the Dormand-Prince 5 method with an adaptive stepper.

See also: Wikipedia [1108], Dormand and Prince [287].

In numerical analysis, the Dormand-Prince method, or DOPRI method, is an explicit method for solving ordinary differential equations citep{Dormand1980}. The method is a member of the Runge-Kutta family of ODE solvers. More specifically, it uses six function evaluations to calculate fourth- and fifth-order accurate solutions. The difference between these solutions is then taken to be the error of the (fourth-order) solution. This error estimate is very convenient for adaptive stepsize integration algorithms. Other similar integration methods are Fehlberg (RKF) and Cash-Karp (RKCK).

The Dormand-Prince method has seven stages, but it uses only six function evaluations per step because it has the FSAL (First Same As Last) property: the last stage is evaluated at the same point as the first stage of the next step. Dormand and Prince choose the coefficients of their method to minimize the error of the fifth-order solution. This is the main difference with the Fehlberg method, which was constructed so that the fourth-order solution has a small error. For this reason, the Dormand-Prince method is more suitable when the higher-order solution is used to continue the integration, a practice known as local extrapolation (Shampine 1986; Hairer, Nørsett & Wanner 2008, pp. 178-179).

5.9.8 Fehlberg 78 method, adaptive stepper

ctxboost.**Fehlberg78Adaptive**(*F1*, *F2*, *matInput*, *StartTime*, *EndTime*, \mathrm{d}t, *epsabs*, *epsrel*)

Solves Ordinary differential equations using the Fehlberg 78 method with an adaptive stepper.

See also: Wikipedia [1118], Fehlberg [299].

In mathematics, the Runge-Kutta-Fehlberg method (or Fehlberg method) is an algorithm in numerical analysis for the numerical solution of ordinary differential equations. It was developed by the German mathematician Erwin Fehlberg and is based on the large class of Runge-Kutta methods.

The novelty of Fehlberg's method is that it is an embedded method from the Runge-Kutta family, meaning that identical function evaluations are used in conjunction with each other to create methods of varying order and similar error constants. The method presented in Fehlberg's 1969 paper has been dubbed the RKF45 method, and is a method of order O(h4) with an error estimator of order O(h5).[1] By performing one extra calculation, the error in the solution can be estimated and controlled by using the higher-order embedded method that allows for an adaptive stepsize to be determined automatically.

5.9.9 Bulirsch-Stoer method, adaptive stepper

ctxboost.**BulirschStoerAdaptive**(*F1*, *F2*, *matInput*, *StartTime*, *EndTime*, *mathrm{d}t*, *epsabs*, *epsrel*)

Solves Ordinary differential equations using the Bulirsch-Stoer method, with an adaptive stepper

See also: Wikipedia [1105], Hairer *et al.* [362].

In numerical analysis, the Bulirsch-Stoer algorithm is a method for the numerical solution of ordinary differential equations which combines three powerful ideas: Richardson extrapolation, the use of rational function extrapolation in Richardson-type applications, and the modified midpoint method, to obtain numerical solutions to ordinary differential equations (ODEs) with high accuracy and comparatively little computational effort. It is named after Roland Bulirsch and Josef Stoer. It is sometimes called the Gragg-Bulirsch-Stoer (GBS) algorithm because of the importance of a result about the error function of the modified midpoint method, due to William B. Gragg.

5.9.10 Dormand-Prince 5 method, dense output stepper

ctxboost.**DormandPrince5DenseOutput**(*F1*, *F2*, *matInput*, *StartTime*, *EndTime*, \mathrm{d}t, *epsabs*, *epsrel*)

Solves Ordinary differential equations using the Dormand-Prince 5 method, with a dense output stepper.

See also: Wikipedia [1108], Dormand and Prince [287].

In numerical analysis, the Dormand-Prince method, or DOPRI method, is an explicit method for solving ordinary differential equations citep{Dormand1980}. The method is a member of the Runge-Kutta family of ODE solvers. More specifically, it uses six function evaluations to calculate fourth- and fifth-order accurate solutions. The difference between these solutions is then taken to be the error of the (fourth-order) solution. This error estimate is very convenient for adaptive stepsize integration algorithms. Other similar integration methods are Fehlberg (RKF) and Cash-Karp (RKCK).

The Dormand-Prince method has seven stages, but it uses only six function evaluations per step because it has the FSAL (First Same As Last) property: the last stage is evaluated at the same point as the first stage of the next step. Dormand and Prince choose the coefficients of their method to minimize the error of the fifth-order solution. This is the main difference with the Fehlberg method, which was constructed so that the fourth-order solution has a small error. For this reason, the Dormand-Prince method is more suitable when the higher-order solution is used to continue the integration, a practice known as local extrapolation (Shampine 1986; Hairer, Nørsett & Wanner 2008, pp. 178-179).

5.9.11 Bulirsch-Stoer method, dense output stepper

ctxboost.**BulirschStoerDenseOutput**(*F1*, *F2*, *matInput*, *StartTime*, *EndTime*, *mathrm{d}t*, *epsabs*, *epsrel*)

Solves Ordinary differential equations using the Bulirsch-Stoer method, with a dense output stepper.

See also: Wikipedia [1105], Hairer *et al.* [362].

In numerical analysis, the Bulirsch-Stoer algorithm is a method for the numerical solution of ordinary differential equations which combines three powerful ideas: Richardson extrapolation, the use of rational function extrapolation in Richardson-type applications, and the modified midpoint method, to obtain numerical solutions to ordinary differential equations (ODEs) with high accuracy and comparatively little computational effort. It is sometimes called the Gragg-Bulirsch-Stoer (GBS) algorithm because of the importance of a result about the error function of the modified midpoint method, due to William B. Gragg.

5.10 Mpmath: Numerical differentiation

5.10.1 First derivative, using the complex-step derivative approximation

`ctx.deriv1_c`(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

See also: https://nhigham.com/2020/10/06/what-is-the-complex-step-approximation/

See Lai and Crassidis

The complex-step derivative approximation can be derived by approximating a nonlinear function with a complex variable using a Taylor's series expansion:

$$f(x+ih) = f(x) + ihf'(x) - \frac{h^2}{2!}f''(x) - i\frac{h^3}{3!}f^{(3)}(x) + \frac{h^4}{4!}f^{(4)}(x) + \cdots$$

Taking only the imaginary parts of both sides, dividing by h and rearranging gives

$$f'(x) = \frac{\Im\left(f(x+ih)\right)}{h} + O(h^2)$$

Terms with order h^2 or higher can be ignored since the interval h can be chosen up to machine precision. Thus, to within first order the complex-step derivative approximation is given by

$$f'(x) = \frac{\Im\left(f(x+ih)\right)}{h}, E_{\text{trunc}}(h) = \frac{h^2}{6}f^{(3)}(x)$$

where $E_{\text{trunc}}(h)$ denotes the truncation error. Note that this solution is not a function of differences, which ultimately provides better roundoff characteristics than a standard finite difference.

5.10.2 Second derivative, using the complex-step derivative approximation

`ctx.deriv2_c`(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

See also: https://nhigham.com/2020/10/06/what-is-the-complex-step-approximation/

See Lai and Crassidis

5.10.3 Gradient, using the complex-step derivative approximation

`ctx.gradient_c`(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

See also: https://nhigham.com/2020/10/06/what-is-the-complex-step-approximation/

The gradient of a vector function is a simple extension of the scalar case.

5.10.4 Jacobi matrix, using the complex-step derivative approximation

`ctx.jacobi_c`(*f*, *x0*, *solver='secant'*, *tol=None*, *verbose=False*, *verify=True*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

See also: https://nhigham.com/2020/10/06/what-is-the-complex-step-approximation/

The Jacobian of a vector function is a simple extension of the scalar case. This Jacobian is defined by

$$F_x = \begin{pmatrix} \frac{\partial f_1(\boldsymbol{x})}{\partial x_1} & \frac{\partial f_1(\boldsymbol{x})}{\partial x_2} & \dots & \frac{\partial f_1(\boldsymbol{x})}{\partial x_p} & \dots & \frac{\partial f_1(\boldsymbol{x})}{\partial x_n} \\ \frac{\partial f_2(\boldsymbol{x})}{\partial x_1} & \frac{\partial f_2(\boldsymbol{x})}{\partial x_2} & \dots & \frac{\partial f_2(\boldsymbol{x})}{\partial x_p} & \dots & \frac{\partial f_2(\boldsymbol{x})}{\partial x_n} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \frac{\partial f_q(\boldsymbol{x})}{\partial x_1} & \frac{\partial f_q(\boldsymbol{x})}{\partial x_2} & \dots & \frac{\partial f_q(\boldsymbol{x})}{\partial x_p} & \dots & \frac{\partial f_q(\boldsymbol{x})}{\partial x_n} \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ \frac{\partial f_m(\boldsymbol{x})}{\partial x_1} & \frac{\partial f_m(\boldsymbol{x})}{\partial x_2} & \dots & \frac{\partial f_m(\boldsymbol{x})}{\partial x_p} & \dots & \frac{\partial f_m(\boldsymbol{x})}{\partial x_n} \end{pmatrix}$$

The complex-step approximation of the Jacobian is defined by

$$F_x = \frac{1}{h}\Im \begin{pmatrix} f_1(\boldsymbol{x}+ih\boldsymbol{e}_1) & f_1(\boldsymbol{x}+ih\boldsymbol{e}_2) & \cdots & f_1(\boldsymbol{x}+ih\boldsymbol{e}_q) & \cdots & f_1(\boldsymbol{x}+ih\boldsymbol{e}_n) \\ f_2(\boldsymbol{x}+ih\boldsymbol{e}_1) & f_2(\boldsymbol{x}+ih\boldsymbol{e}_2) & \cdots & f_2(\boldsymbol{x}+ih\boldsymbol{e}_q) & \cdots & f_2(\boldsymbol{x}+ih\boldsymbol{e}_n) \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ f_q(\boldsymbol{x}+ih\boldsymbol{e}_1) & f_q(\boldsymbol{x}+ih\boldsymbol{e}_2) & \cdots & f_q(\boldsymbol{x}+ih\boldsymbol{e}_q) & \cdots & f_q(\boldsymbol{x}+ih\boldsymbol{e}_n) \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ f_m(\boldsymbol{x}+ih\boldsymbol{e}_1) & f_m(\boldsymbol{x}+ih\boldsymbol{e}_2) & \cdots & f_m(\boldsymbol{x}+ih\boldsymbol{e}_q) & \cdots & f_m(\boldsymbol{x}+ih\boldsymbol{e}_n) \end{pmatrix}$$

where $\boldsymbol{e}_p$ is the p^{th} column of an n^{th}-order identity matrix and f_q is the q^{th} equation of $\boldsymbol{f}(\boldsymbol{x})$.

!!! CHECK CODE IN MPMATH !!!

5.10.5 Nth numerical (partial) derivative, using finite differences or numerical quadrature

`ctx.diff`(*f*, *x*, *n=1*, ***options*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Numerically computes the derivative of f, $f'(x)$, or generally for an integer $n \geq 0$, the n-th derivative $f^{(n)}(x)$. A few basic examples are:

```
>>> from xlcalcnet import *
>>> mp.dps = 15; mp.pretty = True
>>> diff(lambda x: x**2 + x, 1.0)
3.0
>>> diff(lambda x: x**2 + x, 1.0, 2)
2.0
>>> diff(lambda x: x**2 + x, 1.0, 3)
0.0
>>> nprint([diff(exp, 3, n) for n in range(5)])   # exp'(x) = exp(x)
[20.0855, 20.0855, 20.0855, 20.0855, 20.0855]
```

Even more generally, given a tuple of arguments $(x_1, \dots, x_k)$ and order $(n_1, \dots, n_k)$, the partial derivative $f^{(n_1,\dots,n_k)}(x_1, \dots, x_k)$ is evaluated. For example:

```
>>> diff(lambda x,y: 3*x*y + 2*y - x, (0.25, 0.5), (0,1))
2.75
>>> diff(lambda x,y: 3*x*y + 2*y - x, (0.25, 0.5), (1,1))
3.0
```

Options

The following optional keyword arguments are recognized:

`method`
Supported methods are `'step'` or `'quad'`: derivatives may be computed using either a finite difference with a small step size h (default), or numerical quadrature.

direction
Direction of finite difference: can be -1 for a left difference, 0 for a central difference (default), or +1 for a right difference; more generally can be any complex number.

addprec
Extra precision for h used to account for the function's sensitivity to perturbations (default = 10).

relative
Choose h relative to the magnitude of x, rather than an absolute value; useful for large or tiny x (default = False).

h
As an alternative to `addprec` and `relative`, manually select the step size h.

singular
If True, evaluation exactly at the point x is avoided; this is useful for differentiating functions with removable singularities. Default = False.

radius
Radius of integration contour (with `method = 'quad'`). Default = 0.25. A larger radius typically is faster and more accurate, but it must be chosen so that f has no singularities within the radius from the evaluation point.

A finite difference requires $n+1$ function evaluations and must be performed at $(n+1)$ times the target precision. Accordingly, f must support fast evaluation at high precision.

With integration, a larger number of function evaluations is required, but not much extra precision is required. For high order derivatives, this method may thus be faster if f is very expensive to evaluate at high precision.

Further examples

The direction option is useful for computing left- or right-sided derivatives of nonsmooth functions:

```
>>> diff(abs, 0, direction=0)
0.0
>>> diff(abs, 0, direction=1)
1.0
>>> diff(abs, 0, direction=-1)
-1.0
```

More generally, if the direction is nonzero, a right difference is computed where the step size is multiplied by sign(direction). For example, with direction=+j, the derivative from the positive imaginary direction will be computed:

```
>>> diff(abs, 0, direction=j)
(0.0 - 1.0j)
```

With integration, the result may have a small imaginary part even even if the result is purely real:

```
>>> diff(sqrt, 1, method='quad')
(0.5 - 4.59...e-26j)
>>> chop(_)
0.5
```

Adding precision to obtain an accurate value:

```
>>> diff(cos, 1e-30)
0.0
>>> diff(cos, 1e-30, h=0.0001)
-9.99999998328279e-31
>>> diff(cos, 1e-30, addprec=100)
-1.0e-30
```

5.10.6 Function object which evaluates the nth derivative of a given function

`ctx.diffun`(*f*, *n=1*, ***options*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Given a function f, returns a function $g(x)$ that evaluates the nth derivative $f^{(n)}(x)$:

```
>>> from xlcalcnet import *
>>> mp.dps = 15; mp.pretty = True
>>> cos2 = diffun(sin)
>>> sin2 = diffun(sin, 4)
>>> cos(1.3), cos2(1.3)
(0.267498828624587, 0.267498828624587)
>>> sin(1.3), sin2(1.3)
(0.963558185417193, 0.963558185417193)
```

The function f must support arbitrary precision evaluation. See `diff()` for additional details and supported keyword options.

5.10.7 Forward difference, based on a given sequence

`ctx.difference`(*s*, *n*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Given a sequence (s_k) containing at least $n+1$ items, returns the n-th forward difference,

$$\Delta^n = \sum_{k=0}^{\infty} (-1)^{k+n} \binom{n}{k} s_k.$$

EXAMPLE !!!!!

5.10.8 Generating a sequence of derivatives

`ctx.diffs`(*f*, *x*, *n=None*, ***options*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Returns a generator that yields the sequence of derivatives

$$f(x), f'(x), f''(x), \ldots, f^{(k)}(x), \ldots$$

With `method='step'`, `diffs()` uses only $O(k)$ function evaluations to generate the first k derivatives, rather than the roughly $O(k^2)$ evaluations required if one calls `diff()` k separate times.

With $n < \infty$, the generator stops as soon as the n-th derivative has been generated. If the exact number of needed derivatives is known in advance, this is further slightly more efficient.

Options are the same as for `diff()`.

Examples

```
>>> from xlcalcnet import *
>>> mp.dps = 15
>>> nprint(list(diffs(cos, 1, 5)))
[0.540302, -0.841471, -0.540302, 0.841471, 0.540302, -0.841471]
>>> for i, d in zip(range(6), diffs(cos, 1)):
...     print("%s %s" % (i, d))
...
0 0.54030230586814
1 -0.841470984807897
```

(continues on next page)

(continued from previous page)

2 -0.54030230586814
3 0.841470984807897
4 0.54030230586814
5 -0.841470984807897
```

5.10.9 Composition of derivatives

`ctx.diffs_prod`(*factors*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Given a list of N iterables or generators yielding $f_k(x), f_k'(x), f_k''(x), \ldots$ for $k = 1, \ldots, N$, generate $g(x), g'(x), g''(x), \ldots$ where $g(x) = f_1(x) f_2(x) \cdots f_N(x)$.

At high precision and for large orders, this is typically more efficient than numerical differentiation if the derivatives of each $f_k(x)$ admit direct computation.

Note: This function does not increase the working precision internally, so guard digits may have to be added externally for full accuracy.

Examples

```
>>> from xlcalcnet import *
>>> mp.dps = 15; mp.pretty = True
>>> f = lambda x: exp(x)*cos(x)*sin(x)
>>> u = diffs(f, 1)
>>> v = mp.diffs_prod([diffs(exp,1), diffs(cos,1), diffs(sin,1)])
>>> next(u); next(v)
1.23586333600241
1.23586333600241
>>> next(u); next(v)
0.104658952245596
0.104658952245596
>>> next(u); next(v)
-5.96999877552086
-5.96999877552086
>>> next(u); next(v)
-12.4632923122697
-12.4632923122697
```

5.10.10 Composition of exponential of derivatives

`ctx.diffs_exp`(*fdiffs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Given an iterable or generator yielding $f(x), f'(x), f''(x), \ldots$ generate $g(x), g'(x), g''(x), \ldots$ where $g(x) = \exp(f(x))$.

At high precision and for large orders, this is typically more efficient than numerical differentiation if the derivatives of $f(x)$ admit direct computation.

Note: This function does not increase the working precision internally, so guard digits may have to be added externally for full accuracy.

Examples

The derivatives of the gamma function can be computed using logarithmic differentiation:

```
.. code-block:: pycon
```

```
>>> from xlcalcnet import *
>>> mp.dps = 15; mp.pretty = True
>>>
>>> def diffs_loggamma(x):
...     yield loggamma(x)
...     i = 0
...     while 1:
...         yield psi(i,x)
...         i += 1
...
>>> u = diffs_exp(diffs_loggamma(3))
>>> v = diffs(gamma, 3)
>>> next(u); next(v)
2.0
2.0
>>> next(u); next(v)
1.84556867019693
1.84556867019693
>>> next(u); next(v)
2.49292999190269
2.49292999190269
>>> next(u); next(v)
3.44996501352367
3.44996501352367
```

5.10.11 Fractional derivatives / differintegration

`ctx.differint`(*f*, *x*, *n=1*, *x0=0*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Calculates the Riemann-Liouville differintegral, or fractional derivative, defined by

$$ {}_{x_0}\mathbb{D}_x^n f(x) = \frac{1}{\Gamma(m-n)} \frac{\mathrm{d}^m}{\mathrm{d}x^m} \int_{x_0}^{x} (x-t)^{m-n-1} f(t) \mathrm{d}t $$

where f is a given (presumably well-behaved) function, x is the evaluation point, n is the order, and x_0 is the reference point of integration (m is an arbitrary parameter selected automatically).

With $n = 1$, this is just the standard derivative $f'(x)$; with $n = 2$, the second derivative $f''(x)$, etc. With $n = -1$, it gives $\int_{x_0}^{x} f(t)\mathrm{d}t$, with $n = -2$ it gives $\int_{x_0}^{x} \left(\int_{x_0}^{t} f(u) du \right) \mathrm{d}t$, etc.

As n is permitted to be any number, this operator generalizes iterated differentiation and iterated integration to a single operator with a continuous order parameter.

Examples

There is an exact formula for the fractional derivative of a monomial x^p, which may be used as a reference. For example, the following gives a half-derivative (order 0.5):

```
>>> from xlcalcnet import *
>>> mp.dps = 15; mp.pretty = True
>>> x = mpf(3); p = 2; n = 0.5
>>> differint(lambda t: t**p, x, n)
7.81764019044672
>>> gamma(p+1)/gamma(p-n+1) * x**(p-n)
7.81764019044672
```

Another useful test function is the exponential function, whose integration / differentiation formula easy generalizes to arbitrary order. Here we first compute a third derivative, and then a triply nested integral. (The reference point x_0 is set to $-\infty$ to avoid nonzero endpoint terms.):

```
>>> differint(lambda x: exp(pi*x), -1.5, 3)
0.278538406900792
>>> exp(pi*-1.5) * pi**3
0.278538406900792
>>> differint(lambda x: exp(pi*x), 3.5, -3, -inf)
1922.50563031149
>>> exp(pi*3.5) / pi**3
1922.50563031149
```

However, for noninteger n, the differentiation formula for the exponential function must be modified to give the same result as the Riemann-Liouville differintegral:

```
>>> x = mpf(3.5)
>>> c = pi
>>> n = 1+2*j
>>> differint(lambda x: exp(c*x), x, n)
(-123295.005390743 + 140955.117867654j)
>>> x**(-n) * exp(c)**x * (x*c)**n * gammainc(-n, 0, x*c) / gamma(-n)
(-123295.005390743 + 140955.117867654j)
```

5.10.12 Taylor series

`ctx.`**`taylor`**(*f*, *x*, *n*, ***options*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Produces a degree-n Taylor polynomial around the point x of the given function f. The coefficients are returned as a list.

```
>>> from xlcalcnet import *
>>> mp.dps = 15; mp.pretty = True
>>> nprint(chop(taylor(sin, 0, 5)))
[0.0, 1.0, 0.0, -0.166667, 0.0, 0.00833333]
```

The coefficients are computed using high-order numerical differentiation. The function must be possible to evaluate to arbitrary precision. See `diff()` for additional details and supported keyword options.

Note that to evaluate the Taylor polynomial as an approximation of f, e.g. with `polyval()`, the coefficients must be reversed, and the point of the Taylor expansion must be subtracted from the argument:

```
>>> p = taylor(exp, 2.0, 10)
>>> polyval(p[::-1], 2.5 - 2.0)
12.1824939606092
>>> exp(2.5)
12.1824939607035
```

5.10.13 Solving an ODE using high-order Taylor series

`ctx.`**`odefun`**(*F*, *x0*, *y0*, *tol=None*, *degree=None*, *method='taylor'*, *verbose=False*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Returns a function $y(x) = [y_0(x), y_1(x), \ldots, y_n(x)]$ that is a numerical solution of the $n+1$-dimensional first-order ordinary differential equation (ODE) system

$$
\begin{aligned}
y_0'(x) &= F_0(x, [y_0(x), y_1(x), \ldots, y_n(x)]) \\
y_1'(x) &= F_1(x, [y_0(x), y_1(x), \ldots, y_n(x)]) \\
&\vdots \\
y_n'(x) &= F_n(x, [y_0(x), y_1(x), \ldots, y_n(x)])
\end{aligned}
$$

The derivatives are specified by the vector-valued function *F* that evaluates $[y_0', \ldots, y_n'] = F(x, [y_0, \ldots, y_n])$. The initial point x_0 is specified by the scalar argument *x0*, and the initial value $y(x_0) = [y_0(x_0), \ldots, y_n(x_0)]$ is specified by the vector argument *y0*.

For convenience, if the system is one-dimensional, you may optionally provide just a scalar value for *y0*. In this case, *F* should accept a scalar *y* argument and return a scalar. The solution function *y* will return scalar values instead of length-1 vectors.

Evaluation of the solution function $y(x)$ is permitted for any $x \geq x_0$.

A high-order ODE can be solved by transforming it into first-order vector form. This transformation is described in standard texts on ODEs. Examples will also be given below.

Options, speed and accuracy

By default, `odefun()` uses a high-order Taylor series method. For reasonably well-behaved problems, the solution will be fully accurate to within the working precision. Note that *F* must be possible to evaluate to very high precision for the generation of Taylor series to work.

To get a faster but less accurate solution, you can set a large value for *tol* (which defaults roughly to *eps*). If you just want to plot the solution or perform a basic simulation, *tol = 0.01* is likely sufficient.

The *degree* argument controls the degree of the solver (with *method='taylor'*, this is the degree of the Taylor series expansion). A higher degree means that a longer step can be taken before a new local solution must be generated from *F*, meaning that fewer steps are required to get from x_0 to a given x_1. On the other hand, a higher degree also means that each local solution becomes more expensive (i.e., more evaluations of *F* are required per step, and at higher precision).

The optimal setting therefore involves a tradeoff. Generally, decreasing the *degree* for Taylor series is likely to give faster solution at low precision, while increasing is likely to be better at higher precision.

The function object returned by `odefun()` caches the solutions at all step points and uses polynomial interpolation between step points. Therefore, once $y(x_1)$ has been evaluated for some x_1, $y(x)$ can be evaluated very quickly for any $x_0 \leq x \leq x_1$. and continuing the evaluation up to $x_2 > x_1$ is also fast.

Examples of first-order ODEs

We will solve the standard test problem $y'(x) = y(x), y(0) = 1$ which has explicit solution $y(x) = \exp(x)$:

```
>>> from xlcalcnet import *
>>> mp.dps = 15; mp.pretty = True
>>> f = odefun(lambda x, y: y, 0, 1)
>>> for x in [0, 1, 2.5]:
...     print((f(x), exp(x)))
...
(1.0, 1.0)
(2.71828182845905, 2.71828182845905)
(12.1824939607035, 12.1824939607035)
```

The solution with high precision:

```
>>> mp.dps = 50
>>> f = odefun(lambda x, y: y, 0, 1)
>>> f(1)
2.7182818284590452353602874713526624977572470937
>>> exp(1)
2.7182818284590452353602874713526624977572470937
```

Using the more general vectorized form, the test problem can be input as (note that *f* returns a 1-element vector):

```
>>> mp.dps = 15
>>> f = odefun(lambda x, y: [y[0]], 0, [1])
>>> f(1)
[2.71828182845905]
```

`odefun()` can solve nonlinear ODEs, which are generally impossible (and at best difficult) to solve analytically. As an example of a nonlinear ODE, we will solve $y'(x) = x\sin(y(x))$ for $y(0) = \pi/2$. An exact solution happens to be known for this problem, and is given by $y(x) = 2\tan^{-1}\left(\exp\left(x^2/2\right)\right)$:

```
>>> f = odefun(lambda x, y: x*sin(y), 0, pi/2)
>>> for x in [2, 5, 10]:
...     print((f(x), 2*atan(exp(mpf(x)**2/2))))
...
(2.87255666284091, 2.87255666284091)
(3.14158520028345, 3.14158520028345)
(3.14159265358979, 3.14159265358979)
```

If F is independent of y, an ODE can be solved using direct integration. We can therefore obtain a reference solution with `quad()`:

```
>>> f = lambda x: (1+x**2)/(1+x**3)
>>> g = odefun(lambda x, y: f(x), pi, 0)
>>> g(2*pi)
0.72128263801696
>>> quad(f, [pi, 2*pi])
0.72128263801696
```

Examples of second-order ODEs

We will solve the harmonic oscillator equation $y''(x)+y(x) = 0$. To do this, we introduce the helper functions $y_0 = y, y_1 = y_0'$ whereby the original equation can be written as $y_1' + y_0' = 0$. Put together, we get the first-order, two-dimensional vector ODE

$$\begin{cases} y_0' = y_1 \\ y_1' = -y_0 \end{cases}$$

To get a well-defined IVP, we need two initial values. With $y(0) = y_0(0) = 1$ and $-y'(0) = y_1(0) = 0$, the problem will of course be solved by $y(x) = y_0(x) = \cos(x)$ and $-y'(x) = y_1(x) = \sin(x)$. We check this:

```
>>> f = odefun(lambda x, y: [-y[1], y[0]], 0, [1, 0])
>>> for x in [0, 1, 2.5, 10]:
...     nprint(f(x), 15)
...     nprint([cos(x), sin(x)], 15)
...     print("---")
...
[1.0, 0.0]
[1.0, 0.0]
---
[0.54030230586814, 0.841470984807897]
[0.54030230586814, 0.841470984807897]
---
[-0.801143615546934, 0.598472144103957]
[-0.801143615546934, 0.598472144103957]
---
[-0.839071529076452, -0.54402111088937]
[-0.839071529076452, -0.54402111088937]
---
```

Note that we get both the sine and the cosine solutions simultaneously.

5.11 Mpmath: Asymptotic expansions

5.11.1 Edgeworth expansion: general approximation of the pdf, cdf and sf

`ctx.edgeworth`(*x*, *cumulants*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Edgeworth expansion approximations of the pdf, cdf and sf by using the cumulants of the distribution.

See also Wikipedia [1092], Blinnikov and Moessner [32], Wikipedia [1086], Wikipedia [1309].

Using the first 4 cumulants, we have

$$\Pr\left[\frac{u-\mu}{\sigma} \le x\right] = \Phi(x) + \phi(x)\left[\frac{\gamma_1}{6}(1-x^2) + \frac{\gamma_2}{24}(3x-x^3) + \frac{\gamma_1^2}{72}(15x-10x^3+x^5)\right] + O(N^{-3/2})$$

Withers and Nadarajah [1458] and Withers and Nadarajah [1459] have shown that the Edgeworth expansion can also be expressed in terms of standardized cumulants $\alpha_r = \kappa_r/\kappa_2^{r/2}$ (with $\alpha_1 = \alpha_2 = 0$), partial exponential Bell polynomials $B_{r,k}(\boldsymbol{\alpha})$, $\boldsymbol{\alpha} = (\alpha_1, \cdots, \alpha_r)$, and Hermite polynomials $H_r(x)$:

$$f(x) = \phi(x) + \phi(x)\sum_{j=1}^{\infty} h_{1j}(x) n^{-j/2}, \quad \text{where}$$

$$h_{1j}(x) = \sum_{k=1}^{j} B_{r,k}(\boldsymbol{\alpha}) H_r(x)/r!, \quad \text{with } r = j+2k.$$

$$F(x) = \Phi(x) - \phi(x)\sum_{j=1}^{\infty} h_{0j}(x) n^{-j/2},$$

$$1 - F(x) = \Phi(-x) + \phi(x)\sum_{j=1}^{\infty} h_{0j}(x) n^{-j/2}, \quad \text{where}$$

$$h_{0j}(x) = \sum_{k=1}^{j} B_{r,k}(\boldsymbol{\alpha}) H_{r-1}(x)/r!, \quad \text{with } r = j+2k.$$

The partial Bell polynomials can be computed efficiently by a recurrence relation:

$$B_{r,k}(\boldsymbol{\alpha}) = \sum_{i=1}^{r-k+1} \binom{r-1}{i-1} \alpha_i B_{r-i,k-1}(\boldsymbol{\alpha}), \quad \text{where}$$

$$B_{0,0} = 1; \quad B_{r,0} = 0 \text{ (for } r \ge 1); \quad B_{0,k} = 0 \text{ (for } k \ge 1); \quad B_{r,1}(\boldsymbol{\alpha}) = \alpha_r.$$

The Hermite polynomials are defined by

$$H_0(x) = 1, \quad H_1(x) = x, \quad H_{r+1}(x) = xH_r(x) - rH_{r-1}(x)$$

The following code shows how to call the Edgeworth expansion for the central cdf.

```
def EdgeworthWhithersDemo(self):
    Order = 30
    F = 100
    X = mp.mpf(110)

    kappa = mp.matrix(Order+1, 1)
    kappa[1] = F
    for i in range(2, Order+1):
        kappa[i] = kappa[i - 1] * 2 * (i - 1)

    LeftTail1, RightTail1 = self.EdgeworthWhithers(X, Order, kappa)
    print("EdgeworthWhithers LeftTail1: ", LeftTail1, " RightTail1: ",  RightTail1)
```

This gives the following results:

```

5.11.2 Cornish-Fisher expansion: general approximation of the qtf and isf

`ctx.cornish_fisher`(*x*, *cumulants*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Cornish-Fisher approximation of the quantile by using the cumulants of the distribution.

The quantiles of many distribution functions can be approximated by the classical Cornish and Fisher expansion Cornish and Fisher [186], Fisher and Cornish [337]), provided that the cumulants κ_r of the distribution are known (see also Wikipedia [1089]):

$$x = z + \sum_{k=1}^{\infty} n^{-k/2} \xi_k(z)$$

where $\xi_k(z)$ is the collection of all the terms that belong to the k-th power of $n^{-1/2}$. It seems to be easier to describe algorithm AS269 (see Lee and Lin [404]), which is used to calculate the k-th adjustment term $\xi_k(z)$, by giving a program which implements it, rather than to describe it using mathematical formulas:

```
def CornishFisherLee(self, r, x0, ac, adj):
    a = iv.matrix(r+3, 1); d = iv.matrix(r+3, 1)
    h = iv.matrix(3 * (r+3), 1)
    p = iv.matrix((3 * (r+3)) * ((r+3) + 1) // 2, 1)
    x = iv.mpf(x0); cc = -1
    for j in range(1, r+1):
        a[j] = cc * ac[j] / ((j + 1) * (j + 2))
        cc = -cc
    h[1] = -x; h[2] = x * x - 1
    for j in range(3, (3 * r)+1):
        h[j] = -(x * h[j - 1] + (j - 1) * h[j - 2])
    d[1] = -a[1] * h[2]; adj[1] = d[1]; p[1] = d[1]
    p[3] = a[1]; fac = iv.mpf(1); ja = 0
    for j in range(2, r+1):
        fac = fac * j
        bc = iv.mpf(1)
        ja = ja + 3 * (j - 1)
        jb = ja
        for k in range(1, j):
            bcd = bc * d[k]
            bca = bc * a[k]
            jb -= 3 * (j - k)
            for m in range(1, (3 * (j - k))+1):
                jbl = jb + m; jal = ja + m
                p[jal + 1] += bcd * p[jbl]
```

(continues on next page)

(continued from previous page)

```
            p[jal + k + 2] += bca * p[jbl]
        bc = (bc * (j - k)) / k
    p[ja + j + 2] += a[j]; d[j] = 0
    for m in range(2, (3 * j)+1):
        d[j] -= p[ja + m] * h[m - 1]
    p[ja + 1] = d[j]
    adj[j] = d[j] / fac
```

However, if one prefers mathematical formulas, Jaschke [379] gives the following description of the algorithm: "Lee developed a recurrence formula for the k-th adjustment term $\xi_k(z)$ in the Cornish-Fisher expansion, which is implemented in the algorithm AS269 :

$$\xi_k(H) = a_k H^{*(k+1)} - \sum_{j=1}^{k-1} \frac{j}{k} \left(\xi_{k-j}(H) - \xi_{k-j}\right) * \left(\xi_j - a_j H^{*(j+1)}\right) * H, \quad \text{where } a_k = \frac{\kappa_{k+2}}{(k+2)!}.$$

$\xi_k(H)$ is a formal polynomial expression in H with the usual algebraic relations between the summation "$+$" and the "multiplication" "$*$". Once $\xi_k(H)$ is multiplied out in $*$-powers of H, each H^{*k} is to be interpreted as the Hermite polynomial H_k and then the whole term becomes a polynomial in z with the "normal" multiplication "$\cdot$". ξ_k denotes the scalar that results when the "normal" polynomial $\xi_k(H)$ is evaluated at the fixed quantile z, while $\xi_k(H)$ denotes the expression in the $(+, *)$-algebra. In this formula the adjustment of a given order is calculated recursively, the values of lower order adjustments being used in each stage of calculation."

5.11.3 Sheppard correction, cumulants

`ctx.sheppard`(*cumulants*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Returns the Sheppard correction term for a vector of cumulants.

The Sheppard correction is typically applied to the cumulants computed from normally distributed data which have been binned. If κ_r^* is the r-th cumulant of an ungrouped distribution and κ_r the r-th cumulant of an grouped distribution with class interval c, the corrected cumulants (under rather restrictive conditions) are

$$\kappa_r^* = \begin{cases} \kappa_r & \text{for } r \text{ odd} \\ \kappa_r - \frac{B_r}{r} c^r & \text{for } r \text{ even.} \end{cases}$$

where B_r is the r-th Bernoulli number. The same correction can be applied to the cumulants of the continuity-corrected test statistic of a random variable following a lattice distribution with step c. The (continuous) Edgeworth and Cornish-Fisher expansions using these corrected cumulants will then achieve the usual $o(n^{1-r/2})$ error terms of these expansions (see Kolassa and McCullagh [396]), despite the fact that the approximated CDF is discontinuous with jumps of order $O(n^{-1/2})$.

A similar correction can be applied to the cumulant generating function (and its derivatives), as it is needed by the Lugannani-Rice saddle point approximation.

5.11.4 The Sheppard correction, cumulant generating function

`ctx.sheppard_per_cgf`(*cgf*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Returns the Sheppard correction term for cumulant generating function of a discrete ("lattice") random variable.

The Sheppard correction is typically applied to the cumulants computed from normally distributed data which have been binned. If κ_r^* is the r-th cumulant of an ungrouped distribution and κ_r the r-th cumulant of an grouped distribution with class interval c, the corrected cumulants (under rather restrictive conditions) are

$$\kappa_r^* = \begin{cases} \kappa_r & \text{for } r \text{ odd} \\ \kappa_r - \frac{B_r}{r} c^r & \text{for } r \text{ even.} \end{cases}$$

where B_r is the r-th Bernoulli number. The same correction can be applied to the cumulants of the continuity-corrected test statistic of a random variable following a lattice distribution with step c. The (continuous) Edgeworth and Cornish-Fisher expansions using these corrected cumulants will then achieve the usual $o(n^{1-r/2})$ error terms of these expansions (see Kolassa and McCullagh [396]), despite the fact that the approximated CDF is discontinuous with jumps of order $O(n^{-1/2})$.

A similar correction can be applied to the cumulant generating function (and its derivatives), as it is needed by the Lugannani-Rice saddlepoint approximation.

5.11.5 Lugannini-Rice expansion: general approximation of the pdf, cdf, and sf

`ctx.luggannini_rice`(*x*, *s*, *poly_t cgf_series*)

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Lugannini-Rice saddlepoint approximation of the pdf by using the cumulant generating function and its derivatives.

See also Butler [165], Daniels [195], Daniels [196], Lugannani and Rice [410], Wikipedia [1124], Wikipedia [1140].

Suppose the moment generating function of the random variable X is analytic and given by $M(t)$ for t in some open neighbourhood of zero. Let $K(t) = \log(M(t))$ be the cumulant generating function of X, and denote by $K^{(j)}(t)$ the j^{th} derivative of $K(t)$.

Let $F(x)$ and $f(x)$ denote the CDF and pdf of X, respectively, and $\Phi(\cdot)$ and $\phi(\cdot)$ denote the CDF and pdf of the normal distribution, respectively. Let s be the solution to the saddlepoint equation $K^{(1)}(s) = x$, which in general needs to be solved numerically. Then

$$f(x) \approx \phi(w) \sum_{k=0}^{\infty} C_k,$$

$$F(x) \approx \Phi(w) + \phi(w) \sum_{k=0}^{\infty} (A_k - B_k), \quad \text{and}$$

$$1 - F(x) \approx \Phi(-w) - \phi(w) \sum_{k=0}^{\infty} (A_k - B_k), \quad \text{where}$$

$$w = \operatorname{sgn}(s)\sqrt{2(sK^{(1)}(s) - K(s))}; \quad t = \sqrt{K^{(2)}(s)}; \quad u = st.$$

The coefficients A_k, B_k and C_k are calculated as follows:

$$A_0 = \frac{1}{u}, \quad A_j = A_0 \sum_{n=0}^{2j} \left(\frac{1}{u}\right)^{2j-n} \sum_{m=0}^{n} d_{m,n} \, (-2)^{m+j} \left(\tfrac{1}{2}\right)_{m+j},$$

where $d_{m,n}$ is computed (with $d_{0,0} = 1$ and $d_{0,n} = 0$ for $n > 0$) from

$$d_{m+1,n+1} = \frac{1}{n+1} \sum_{j=1}^{n-m+1} \frac{j}{(j+2)!} \frac{K^{(j+2)}(s)}{t^{j+2}} \, d_{m,n-j+1}, \quad 0 \le m \le n.$$

$$B_0 = \frac{1}{w}, \quad B_j = \frac{-2(j - \frac{1}{2})B_{j-1}}{w^2}.$$

$$C_0 = \frac{1}{t}, \quad C_j = \sum_{m=1}^{2j} d_{m,2j} \, (-2)^{m+j} \left(\tfrac{1}{2}\right)_{m+j}.$$

5.11.6 Jensen expansion: general approximation of the qtf and isf

`ctx.jensen_inv(q, s, x0, poly_t cgf_series)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Jensen approximation of the qtf and isf

Using the same notation as above, Jensen [380] derived the following approximation (see also Wang [794]):

$$F(x) \approx \Phi(r(s)), \quad \text{where}$$

$$w(s) = \operatorname{sgn}(s)\sqrt{2(sK'(s) - K(s))},$$

$$u(s) = s\sqrt{K''(s)},$$

$$r(s) = w(s) + \frac{v(s)}{w(s)}, \quad \text{where } v(s) = \log\frac{u(s)}{w(s)}.$$

To obtain an approximation to the α-quantile of $F(x)$, we start with a reasonable estimate, say, x_0, and convert this to the corresponding saddlepoint, say s_0, such that $K'(s_0) = x_0$.

Let z_α be the α-quantile of the standard normal distribution. We wish to solve for s in the equation

$$h(s) = w(s) + \frac{v(s)}{w(s)} - z_\alpha = 0.$$

Starting with $n = 0$, we compute successive approximations using Newton iterations as

$$s_{n+1} = s_n - \frac{h(s_n)}{h'(s_n)}, \quad \text{where}$$

$$h'(s) = w'(s) + \frac{w(s)u'(s) - u(s)w'(s)\,(v(s)+1)}{u(s)w(s)^2},$$

$$w'(s) = \operatorname{sgn}(s)\frac{sK''(s)}{\sqrt{2sK'(s) - 2K(s)}} = \operatorname{sgn}(s)\frac{sK''(s)}{w(s)},$$

$$u'(s) = \frac{sK^{(3)}(s) + 2K''(s)}{2\sqrt{K''(s)}}.$$

The final estimate x_{n+1} of the α-quantile of $F(x)$ is then obtained as $x_{n+1} = K'(s_{n+1})$.

5.11.7 Box-Davis expansion: general approximation of the pdf, cdf and sf

`ctx.box_davis_expansion(x, f, rho, omega)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

Calculates the Box-Davis approximation of the pdf, cdf and sf

The Box-Davis expansion supports a general class of random variables, say X, with absolutely continuous distribution functions, for which the logarithm of the characteristic function, say $\log[C_X(t)]$, may be validly represented by an asymptotic series

$$\log[C_X(t)] \sim -\frac{1}{2}f\log(1-2it) + \sum_{r=1}^{\infty}\omega_r(\rho)\left[(1-2it)^{-r} - 1\right],$$

corresponding to a limiting chi-squared distribution with f degrees of freedom, where ρ is chosen in such a way that $\omega_1 = 0$, whenever this is possible.

The first comprehensive review of this type of expansion for the CDF is due to Box (see Box [35]). The corresponding expansion for the inverse CDF is due to Davis (see Davis [204]), who also gave algorithms for variables with characteristic functions

different from those considered by Box. We refer therefore to this system of asymptotic expansions as the Box-Davis expansion. Distributions covered by this expansion include the beta distribution, the distribution of the product of independent beta variables, Wilks' Lambda, Mauchley's test for sphericity, Bartletts test for equality of independent covariance matrices, Hotelling's T^2 and Pillai's V. For more information, see Anderson [9] and Ginzberg [349].

Let θ be a suitably chosen constant (which will usually be proportional to sample size). We define

$$a_0 = 1; \quad a_j = \frac{1}{j}\sum_{l=1}^{j} l\omega_l a_{j-l}, \quad j > 0.$$

$$\log(K_B) = -\sum_{j=1}^{r} \omega_j + O(\theta^{-r-1}),$$

Then X follows asymptotically (with $\theta \to \infty$) a χ^2-distribution with f degrees of freedom, and the pdf, CDF of M can be developed into asymptotic expansions including terms of order $O(\theta^{-r})$, depending only on f, ρ, K_B and a_j:

$$\text{pdf}_X(x)) = \rho K_B \sum_{j=0}^{r} a_j f_{\chi^2_{f+2j}}(\rho x) + O(\theta^{-r-1})$$

$$\text{cdf}_X(x) = K_B \sum_{j=0}^{r} a_j F_{\chi^2_{f+2j}}(\rho x) + O(\theta^{-r-1})$$

$$1 - \text{cdf}_X(x) = K_B \sum_{j=0}^{r} a_j \left[1 - F_{\chi^2_{f+2j}}(\rho x)\right] + O(\theta^{-r-1})$$

Gupta and Tang (see Gupta and Tang [356]) show that the above series are convergent as $r \to \infty$ for fixed $x < 4\pi\theta$.

When calling the following functions, only f, ρ and ω_j need to be supplied by the user. K_B and a_j are calculated internally.

5.11.8 Box-Davis expansion: general approximation of the qtf and isf (for $\omega_1 = 0$)

`ctx.box_davis_expansion_inv(`x, f, *rho*, *omega*`)`

where `ctx` is `ipm`, `dec`, `mpm`, or `gmp`.

The Box-Davis expansion can be inverted efficiently in a two-step procedure. In the first step, an initial estimate is obtained, using the procedure given below. In the second step, the initial estimate is used as starting point of a Newton iteration, using the functions of the previous section.

Assuming $\omega_1 = 0$, an approximation of the quantile function of X, $\text{qtf}_X(q))$, in terms of the quantiles of a χ^2-distribution with f degrees of freedom, say $u = \chi^2_{f,\alpha}$, can be given as $\text{qtf}_X(q)) = (u + 2S)/\rho + O(\theta^{-8})$, where S is a polynomial in u, whose coefficients depend only on f and ω_j (see Davis [204]).

$$\begin{aligned} S &= \omega_2 P_2(u) \\ &+ \omega_3 P_3(u) \\ &+ \omega_4 P_4(u) + \tfrac{1}{2}\omega_2^2 P_{2,2}(u) \\ &+ \omega_5 P_5(u) + \omega_3\omega_2 P_{3,2}(u) \\ &+ \omega_6 P_6(u) + \omega_4\omega_2 P_{4,2}(u) + \tfrac{1}{2}\omega_3^2 P_{3,3}(u) + \tfrac{1}{6}\omega_2^3 P_{2,2,2}(u) \\ &+ \omega_7 P_7(u) + \omega_5\omega_2 P_{5,2}(u) + \omega_4\omega_3 P_{4,3}(u) + \tfrac{1}{2}\omega_3\omega_2^2 P_{3,2,2}(u), \end{aligned}$$

$$P_r(u) = \frac{u}{f_1} + \ldots + \frac{u^r}{f_r}, \quad f_r = f(f+2)\ldots(f+2r-2),$$

$$P_{2,2} = -\frac{8u^4(f+3)}{(f_2 f_4)} + \frac{8u^3}{(f_2 f_3)} + \frac{6u^2}{(f f_2)} + \frac{2u}{f^2}$$

$$P_{3,2} = -\frac{12u^5(f+4)}{(f_2f_5)} - \frac{2u^4(f-6)}{(f_2f_4)} + \frac{2u^3(3f+10)}{(f_2f_3)} + \frac{6u^2}{(ff_2)} + \frac{2u}{f^2}$$

$$P_{4,2}(u) = -\frac{16u^6(f+5)}{f_2f_6} - \frac{4u^5(f-4}{f_2f_5}) + \frac{2u^4(3f+14)}{f_2f_4} + \frac{2u^3(3f+10)}{f_2f_3} + \frac{6u^2}{ff_2} + \frac{2u}{f^2},$$

$$P_{3,3}(u) = -\frac{6u^6(3f^2+30f+80)}{f_3f_6} - \frac{6u^5(f_2+2f-16)}{f_3f_5} + \frac{4u^4(f+12)}{f_2f_4} + \frac{4u^3(3f+8)}{f_2f_3} + \frac{6u^2}{ff_2} + \frac{2u}{f^2},$$

$$P_{2,2,2}(u) = \frac{32u^6(7f^2+62f+120)}{f_2^2f_6} - \frac{32u^5(2f^2+37f+96)}{f_2^2f_5} - \frac{8u^4(23f^2+124f+132)}{f_2^2f_4} - \frac{8u^3(f-10)}{ff_2f_3} + \frac{28u^2}{f^2f_2} + \frac{4u}{f^3},$$

$$P_{5,2} = -\frac{20u^7(f+6)}{(f_2f_7)} - \frac{2u^6(3f-10)}{(f_2f_6)} + \frac{2u}{f^2} + 2\sum_{r=2}^{5}\frac{u^r(3f+4r-2)}{f_2f_r}$$

$$P_{4,3}(u) = -\frac{24u^7(f_2+12f+40)}{f_3f_7} - \frac{2u^6(5f_2+18f-80)}{f_3f_6} + \frac{2u^5(f_2+42f+176)}{f_3f_5} + \frac{4u^4(3f+16)}{f_2f_4} + \frac{4u^3(3f+8)}{f_2f_3} + \frac{6u^2}{ff_2} + \frac{2u}{f^2},$$

$$P_{3,2,2}(u) = \frac{192u^7(2f^3+31f^2+154f+240)}{f_2f_3f_7} - \frac{16u^6(4f^3+153f^2+1106f+2160)}{f_2f_3f_6} - \frac{8u^5(35f^3420f^2+1540f+1632)}{f_2f_3f_5} - \frac{4u^4(25f^2+80f+12)}{f_2^2f_4} + \frac{4u^3(7f+38)}{ff_2f_3} + \frac{28u^2}{f^2f_3} + \frac{4u}{f^3}.$$

When calling the following functions, only f, ρ and ω_j need to be supplied by the user. K_B and a_j are calculated internally.

5.12 Mpmath: Function approximation

5.12.1 Pade approximation

`ctx.pade`(a, L, M)

where `ctx` is `dec`, `mpm`, or `gmp`.

Computes a Pade approximation of degree (L, M) to a function. Given at least $L + M + 1$ Taylor coefficients a approximating a function $A(x)$, `pade()` returns coefficients of polynomials P, Q satisfying

$$P = \sum_{k=0}^{L} p_k x^k$$
$$Q = \sum_{k=0}^{M} q_k x^k$$
$$Q_0 = 1$$
$$A(x)Q(x) = P(x) + O(x^{L+M+1})$$

$P(x)/Q(x)$ can provide a good approximation to an analytic function beyond the radius of convergence of its Taylor series (example from G.A. Baker 'Essentials of Pade Approximants' Academic Press, Ch.1A):

```
>>> from xlcalcnet import *
>>> mp.dps = 15; mp.pretty = True
>>> one = mpf(1)
>>> def f(x):
...     return sqrt((one + 2*x)/(one + x))
...
>>> a = taylor(f, 0, 6)
>>> p, q = pade(a, 3, 3)
>>> x = 10
>>> polyval(p[::-1], x)/polyval(q[::-1], x)
1.38169105566806
>>> f(x)
1.38169855941551
```

5.12.2 Chebyshev approximation

`ctx.chebyfit`(f, *interval*, N, *error=False*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Computes a polynomial of degree $N - 1$ that approximates the given function f on the interval $[a, b]$. With `error=True`, `chebyfit()` also returns an accurate estimate of the maximum absolute error; that is, the maximum value of $|f(x) - P(x)|$ for $x \in [a, b]$.

`chebyfit()` uses the Chebyshev approximation formula, which gives a nearly optimal solution: that is, the maximum error of the approximating polynomial is very close to the smallest possible for any polynomial of the same degree.

Chebyshev approximation is very useful if one needs repeated evaluation of an expensive function, such as function defined implicitly by an integral or a differential equation. (For example, it could be used to turn a slow mpmath function into a fast machine-precision version of the same.)

Examples

Here we use `chebyfit()` to generate a low-degree approximation of $f(x) = \cos(x)$, valid on the interval $[1, 2]$:

```
>>> from xlcalcnet import *
>>> mp.dps = 15; mp.pretty = True
>>> poly, err = chebyfit(cos, [1, 2], 5, error=True)
```

(continues on next page)

(continued from previous page)

```
>>> nprint(poly)
[0.00291682, 0.146166, -0.732491, 0.174141, 0.949553]
>>> nprint(err, 12)
1.61351758081e-5
```

The polynomial can be evaluated using `polyval`:

```
>>> nprint(polyval(poly, 1.6), 12)
-0.0291858904138
>>> nprint(cos(1.6), 12)
-0.0291995223013
```

Sampling the true error at 1000 points shows that the error estimate generated by `chebyfit` is remarkably good:

```
>>> error = lambda x: abs(cos(x) - polyval(poly, x))
>>> nprint(max([error(1+n/1000.) for n in range(1000)]), 12)
1.61349954245e-5
```

Choice of degree

The degree N can be set arbitrarily high, to obtain an arbitrarily good approximation. As a rule of thumb, an N-term Chebyshev approximation is good to $N/(b-a)$ decimal places on a unit interval (although this depends on how well-behaved f is). The cost grows accordingly: `chebyfit` evaluates the function $(N^2)/2$ times to compute the coefficients and an additional N times to estimate the error.

Possible issues

One should be careful to use a sufficiently high working precision both when calling `chebyfit` and when evaluating the resulting polynomial, as the polynomial is sometimes ill-conditioned. It is for example difficult to reach 15-digit accuracy when evaluating the polynomial using machine precision floats, no matter the theoretical accuracy of the polynomial. (The option to return the coefficients in Chebyshev form should be made available in the future.)

It is important to note the Chebyshev approximation works poorly if f is not smooth. A function containing singularities, rapid oscillation, etc can be approximated more effectively by multiplying it by a weight function that cancels out the nonsmooth features, or by dividing the interval into several segments.

5.12.3 Fourier series

`ctx.fourier`(*f*, *interval*, *N*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Computes the Fourier series of degree N of the given function on the interval $[a, b]$. More precisely, `fourier()` returns two lists (c, s) of coefficients (the cosine series and sine series, respectively), such that

$$f(x) \sim \sum_{k=0}^{N} c_k \cos(kmx) + s_k \sin(kmx)$$

where $m = 2\pi/(b-a)$.

Note that many texts define the first coefficient as $2c_0$ instead of c_0. The easiest way to evaluate the computed series correctly is to pass it to `fourierval()`.

Examples

The function $f(x) = x$ has a simple Fourier series on the standard interval $[-\pi, \pi]$. The cosine coefficients are all zero (because the function has odd symmetry), and the sine coefficients are rational numbers:

```
>>> from xlcalcnet import *
>>> mp.dps = 15; mp.pretty = True
>>> c, s = fourier(lambda x: x, [-pi, pi], 5)
>>> nprint(c)
[0.0, 0.0, 0.0, 0.0, 0.0, 0.0]
>>> nprint(s)
[0.0, 2.0, -1.0, 0.666667, -0.5, 0.4]
```

This computes a Fourier series of a nonsymmetric function on a nonstandard interval:

```
>>> I = [-1, 1.5]
>>> f = lambda x: x**2 - 4*x + 1
>>> cs = fourier(f, I, 4)
>>> nprint(cs[0])
[0.583333, 1.12479, -1.27552, 0.904708, -0.441296]
>>> nprint(cs[1])
[0.0, -2.6255, 0.580905, 0.219974, -0.540057]
```

It is instructive to plot a function along with its truncated Fourier series:

```
>>> plot([f, lambda x: fourierval(cs, I, x)], I)
```

Fourier series generally converge slowly (and may not converge pointwise). For example, if $f(x) = \cosh(x)$, a 10-term Fourier series gives an L^2 error corresponding to 2-digit accuracy:

```
>>> I = [-1, 1]
>>> cs = fourier(cosh, I, 9)
>>> g = lambda x: (cosh(x) - fourierval(cs, I, x))**2
>>> nprint(sqrt(quad(g, I)))
0.00467963
```

`fourier()` uses numerical quadrature. For nonsmooth functions, the accuracy (and speed) can be improved by including all singular points in the interval specification:

```
>>> nprint(fourier(abs, [-1, 1], 0), 10)
([0.5000441648], [0.0])
>>> nprint(fourier(abs, [-1, 0, 1], 0), 10)
([0.5], [0.0])
```

5.12.4 Fourier series evaluation

`ctx.fourierval`(*series*, *interval*, *x*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Evaluates a Fourier series (in the format computed by by `fourier()` for the given interval) at the point x.

The series should be a pair (c, s) where c is the cosine series and s is the sine series. The two lists need not have the same length.

5.13 Mpmath: Sums, products, limits and extrapolation

5.13.1 Summation of infinite series

`ctx.nsum`(*f*, **intervals*, ***options*)

where `ctx` is `dec`, `mpm`, or `gmp`.

See also: Wikipedia [1119].

Computes the sum

$$S = \sum_{k=a}^{b} f(k)$$

where (a, b) = *interval*, and where $a = -\infty$ and/or $b = \infty$ are allowed, or more generally

$$S = \sum_{k_1=a_1}^{b_1} \cdots \sum_{k_n=a_n}^{b_n} f(k_1, \ldots, k_n)$$

if multiple intervals are given.

Two examples of infinite series that can be summed by `nsum()`, where the first converges rapidly and the second converges slowly, are:

```
>>> from xlcalcnet import *
>>> mp.dps = 15; mp.pretty = True
>>> nsum(lambda n: 1/fac(n), [0, inf])
2.71828182845905
>>> nsum(lambda n: 1/n**2, [1, inf])
1.64493406684823
```

When appropriate, `nsum()` applies convergence acceleration to accurately estimate the sums of slowly convergent series. If the series is finite, `nsum()` currently does not attempt to perform any extrapolation, and simply calls `fsum()`.

Multidimensional infinite series are reduced to a single-dimensional series over expanding hypercubes; if both infinite and finite dimensions are present, the finite ranges are moved innermost. For more advanced control over the summation order, use nested calls to `nsum()`, or manually rewrite the sum as a single-dimensional series.

Options

tol
Desired maximum final error. Defaults roughly to the epsilon of the working precision.

method
Which summation algorithm to use (described below). Default: `'richardson+shanks'`.

maxterms
Cancel after at most this many terms. Default: 10*dps.

steps
An iterable giving the number of terms to add between each extrapolation attempt. The default sequence is [10, 20, 30, 40, ...]. For example, if you know that approximately 100 terms will be required, efficiency might be improved by setting this to [100, 10]. Then the first extrapolation will be performed after 100 terms, the second after 110, etc.

verbose
Print details about progress.

ignore
If enabled, any term that raises `ArithmeticError` or `ValueError` (e.g. through division by zero) is replaced by a zero. This is convenient for lattice sums with a singular term near the origin.

Methods

Unfortunately, an algorithm that can efficiently sum any infinite series does not exist. `nsum()` implements several different algorithms that each work well in different cases. The *method* keyword argument selects a method.

The default method is `'r+s'`, i.e. both Richardson extrapolation and Shanks transformation is attempted. A slower method that handles more cases is `'r+s+e'`. For very high precision summation, or if the summation needs to be fast (for example if multiple sums need to be evaluated), it is a good idea to investigate which one method works best and only use that.

`'richardson'` / `'r'`:
Uses Richardson extrapolation. Provides useful extrapolation when $f(k) \sim P(k)/Q(k)$ or when $f(k) \sim (-1)^k P(k)/Q(k)$ for polynomials P and Q. See `richardson()` for additional information.

`'shanks'` / `'s'`:
Uses Shanks transformation. Typically provides useful extrapolation when $f(k) \sim c^k$ or when successive terms alternate signs. Is able to sum some divergent series. See `shanks()` for additional information.

`'levin'` / `'l'`:
Uses the Levin transformation. It performs better than the Shanks transformation for logarithmic convergent or alternating divergent series. The `'levin_variant'`-keyword selects the variant. Valid choices are "u", "t", "v" and "all" whereby "all" uses all three u,t and v simultanously (This is good for performance comparison in conjunction with "verbose=True"). Instead of the Levin transform one can also use the Sidi-S transform by selecting the method `'sidi'`. See `levin()` for additional details.

`'alternating'` / `'a'`:
This is the convergence acceleration of alternating series developped by Cohen, Villegras and Zagier. See `cohen_alt()` for additional details.

`'euler-maclaurin'` / `'e'`:
Uses the Euler-Maclaurin summation formula to approximate the remainder sum by an integral. This requires high-order numerical derivatives and numerical integration. The advantage of this algorithm is that it works regardless of the decay rate of f, as long as f is sufficiently smooth. See `sumem()` for additional information.

`'direct'` / `'d'`:
Does not perform any extrapolation. This can be used (and should only be used for) rapidly convergent series. The summation automatically stops when the terms decrease below the target tolerance.

Basic examples

A finite sum:

```
>>> nsum(lambda k: 1/k, [1, 6])
2.45
```

Summation of a series going to negative infinity and a doubly infinite series:

```
>>> nsum(lambda k: 1/k**2, [-inf, -1])
1.64493406684823
>>> nsum(lambda k: 1/(1+k**2), [-inf, inf])
3.15334809493716
```

`nsum()` handles sums of complex numbers:

```
>>> nsum(lambda k: (0.5+0.25j)**k, [0, inf])
(1.6 + 0.8j)
```

The following sum converges very rapidly, so it is most efficient to sum it by disabling convergence acceleration:

```
>>> mp.dps = 1000
>>> a = nsum(lambda k: -(-1)**k * k**2 / fac(2*k), [1, inf],
...     method='direct')
```

(continues on next page)

(continued from previous page)

```
>>> b = (cos(1)+sin(1))/4
>>> abs(a-b) < mpf('1e-998')
True
```

Examples with Richardson extrapolation

Richardson extrapolation works well for sums over rational functions, as well as their alternating counterparts:

```
>>> mp.dps = 50
>>> nsum(lambda k: 1 / k**3, [1, inf],
...     method='richardson')
1.2020569031595942853997381615114499907649862923405
>>> zeta(3)
1.2020569031595942853997381615114499907649862923405

>>> nsum(lambda n: (n + 3)/(n**3 + n**2), [1, inf],
...     method='richardson')
2.9348022005446793094172454999380755676568497036204
>>> pi**2/2-2
2.9348022005446793094172454999380755676568497036204

>>> nsum(lambda k: (-1)**k / k**3, [1, inf],
...     method='richardson')
-0.90154267736969571404980362113358749307373971925537
>>> -3*zeta(3)/4
-0.90154267736969571404980362113358749307373971925538
```

Examples with Shanks transformation

The Shanks transformation works well for geometric series and typically provides excellent acceleration for Taylor series near the border of their disk of convergence. Here we apply it to a series for $\log(2)$, which can be seen as the Taylor series for $\log(1+x)$ with $x = 1$:

```
>>> nsum(lambda k: -(-1)**k/k, [1, inf],
...     method='shanks')
0.69314718055994530941723212145817656807550013436025
>>> log(2)
0.69314718055994530941723212145817656807550013436025
```

Here we apply it to a slowly convergent geometric series:

```
>>> nsum(lambda k: mpf('0.995')**k, [0, inf],
...     method='shanks')
200.0
```

Finally, Shanks' method works very well for alternating series where $f(k) = (-1)^k g(k)$, and often does so regardless of the exact decay rate of $g(k)$:

```
>>> mp.dps = 15
>>> nsum(lambda k: (-1)**(k+1) / k**1.5, [1, inf],
...     method='shanks')
0.765147024625408
>>> (2-sqrt(2))*zeta(1.5)/2
0.765147024625408
```

The following slowly convergent alternating series has no known closed-form value. Evaluating the sum a second time at higher precision indicates that the value is probably correct:

```
>>> nsum(lambda k: (-1)**k / log(k), [2, inf],
...     method='shanks')
0.924299897222939
>>> mp.dps = 30
```

(continues on next page)

(continued from previous page)

```
>>> nsum(lambda k: (-1)**k / log(k), [2, inf],
...     method='shanks')
0.92429989722293885595957018136
```

Examples with Levin transformation

The following example calculates Euler's constant as the constant term in the Laurent expansion of zeta(s) at s=1. This sum converges extremly slow because of the logarithmic convergence behaviour of the Dirichlet series for zeta.

```
>>> mp.dps = 30
>>> z = mp.mpf(10) ** (-10)
>>> a = mp.nsum(lambda n: n**(-(1+z)), [1, mp.inf], method = "levin") - 1 / z
>>> print(mp.chop(a - mp.euler, tol = 1e-10))
0.0
```

Now we sum the zeta function outside its range of convergence (attention: This does not work at the negative integers!):

```
>>> mp.dps = 15
>>> w = mp.nsum(lambda n: n ** (2 + 3j), [1, mp.inf], method = "levin", levin_variant = "v")
>>> print(mp.chop(w - mp.zeta(-2-3j)))
0.0
```

The next example resummates an asymptotic series expansion of an integral related to the exponential integral.

```
>>> mp.dps = 15
>>> z = mp.mpf(10)
>>> # exact = mp.quad(lambda x: mp.exp(-x)/(1+x/z),[0,mp.inf])
>>> exact = z * mp.exp(z) * mp.expint(1,z) # this is the symbolic expression for the integral
>>> w = mp.nsum(lambda n: (-1) ** n * mp.fac(n) * z ** (-n), [0, mp.inf], \
...   method = "sidi", levin_variant = "t")
>>> print(mp.chop(w - exact))
0.0
```

Following highly divergent asymptotic expansion needs some care. Firstly we need copious amount of working precision. Secondly the stepsize must not be chosen to large, otherwise nsum may miss the point where the Levin transform converges and reach the point where only numerical garbage is produced due to numerical cancellation.

```
>>> mp.dps = 15
>>> z = mp.mpf(2)
>>> # exact = mp.quad(lambda x: mp.exp( -x * x / 2 - z * x ** 4), [0,mp.inf]) * 2 / mp.sqrt(2 * mp.pi)
>>>  # the following is the symbolic expression for the integral
>>> exact = mp.exp(mp.one / (32 * z)) * mp.besselk(mp.one / 4, \
...   mp.one / (32 * z)) / (4 * mp.sqrt(z * mp.pi))
>>> w = mp.nsum(lambda n: (-z)**n * mp.fac(4 * n) / (mp.fac(n) * mp.fac(2 * n) * (4 ** n)),
...   [0, mp.inf], method = "levin", levin_variant = "t", workprec = 8*mp.prec,
...   steps = [2] + [1 for x in xrange(1000)])
>>> print(mp.chop(w - exact))
0.0
```

The hypergeometric function can also be summed outside its range of convergence:

```
>>> mp.dps = 15
>>> z = 2 + 1j
>>> exact = mp.hyp2f1(2 / mp.mpf(3), 4 / mp.mpf(3), 1 / mp.mpf(3), z)
>>> f = lambda n: mp.rf(2 / mp.mpf(3), n) * mp.rf(4 / mp.mpf(3), n) * z**n \
...   / (mp.rf(1 / mp.mpf(3), n) * mp.fac(n))
>>> v = mp.nsum(f, [0, mp.inf], method = "levin", steps = [10 for x in xrange(1000)])
>>> print(mp.chop(exact-v))
0.0
```

Examples with Cohen's alternating series resummation

The next example sums the alternating zeta function:

```
>>> v = mp.nsum(lambda n: (-1)**(n-1) / n, [1, mp.inf], method = "a")
>>> print(mp.chop(v - mp.log(2)))
0.0
```

The derivate of the alternating zeta function outside its range of convergence:

```
>>> v = mp.nsum(lambda n: (-1)**n * mp.log(n) * n, [1, mp.inf], method = "a")
>>> print(mp.chop(v - mp.diff(lambda s: mp.altzeta(s), -1)))
0.0
```

Examples with Euler-Maclaurin summation

The sum in the following example has the wrong rate of convergence for either Richardson or Shanks to be effective.

```
>>> f = lambda k: log(k)/k**2.5
>>> mp.dps = 15
>>> nsum(f, [1, inf], method='euler-maclaurin')
0.38734195032621
>>> -diff(zeta, 2.5)
0.38734195032621
```

Increasing `steps` improves speed at higher precision:

```
>>> mp.dps = 50
>>> nsum(f, [1, inf], method='euler-maclaurin', steps=[250])
0.38734195032620997271199237593105101319948228874688
>>> -diff(zeta, 2.5)
0.38734195032620997271199237593105101319948228874688
```

Divergent series

The Shanks transformation is able to sum some *divergent* series. In particular, it is often able to sum Taylor series beyond their radius of convergence (this is due to a relation between the Shanks transformation and Pade approximations; see `pade()` for an alternative way to evaluate divergent Taylor series). Furthermore the Levin-transform examples above contain some divergent series resummation.

Here we apply it to $\log(1+x)$ far outside the region of convergence:

```
>>> mp.dps = 50
>>> nsum(lambda k: -(-9)**k/k, [1, inf],
...     method='shanks')
2.3025850929940456840179914546843642076011014886288
>>> log(10)
2.3025850929940456840179914546843642076011014886288
```

A particular type of divergent series that can be summed using the Shanks transformation is geometric series. The result is the same as using the closed-form formula for an infinite geometric series:

```
>>> mp.dps = 15
>>> for n in range(-8, 8):
...     if n == 1:
...         continue
...     print("%s %s %s" % (mpf(n), mpf(1)/(1-n),
...         nsum(lambda k: n**k, [0, inf], method='shanks')))
...
-8.0 0.111111111111111 0.111111111111111
-7.0 0.125 0.125
-6.0 0.142857142857143 0.142857142857143
-5.0 0.166666666666667 0.166666666666667
-4.0 0.2 0.2
-3.0 0.25 0.25
-2.0 0.333333333333333 0.333333333333333
-1.0 0.5 0.5
```

(continues on next page)

(continued from previous page)

```
0.0 1.0 1.0
2.0 -1.0 -1.0
3.0 -0.5 -0.5
4.0 -0.333333333333333 -0.333333333333333
5.0 -0.25 -0.25
6.0 -0.2 -0.2
7.0 -0.166666666666667 -0.166666666666667
```

Multidimensional sums

Any combination of finite and infinite ranges is allowed for the summation indices:

```
>>> mp.dps = 15
>>> nsum(lambda x,y: x+y, [2,3], [4,5])
28.0
>>> nsum(lambda x,y: x/2**y, [1,3], [1,inf])
6.0
>>> nsum(lambda x,y: y/2**x, [1,inf], [1,3])
6.0
>>> nsum(lambda x,y,z: z/(2**x*2**y), [1,inf], [1,inf], [3,4])
7.0
>>> nsum(lambda x,y,z: y/(2**x*2**z), [1,inf], [3,4], [1,inf])
7.0
>>> nsum(lambda x,y,z: x/(2**z*2**y), [3,4], [1,inf], [1,inf])
7.0
```

Some nice examples of double series with analytic solutions or reductions to single-dimensional series (see MathWorld [1032]):

```
>>> nsum(lambda m, n: 1/2**(m*n), [1,inf], [1,inf])
1.60669515241529
>>> nsum(lambda n: 1/(2**n-1), [1,inf])
1.60669515241529

>>> nsum(lambda i,j: (-1)**(i+j)/(i**2+j**2), [1,inf], [1,inf])
0.278070510848213
>>> pi*(pi-3*ln2)/12
0.278070510848213

>>> nsum(lambda i,j: (-1)**(i+j)/(i+j)**2, [1,inf], [1,inf])
0.129319852864168
>>> altzeta(2) - altzeta(1)
0.129319852864168

>>> nsum(lambda i,j: (-1)**(i+j)/(i+j)**3, [1,inf], [1,inf])
0.0790756439455825
>>> altzeta(3) - altzeta(2)
0.0790756439455825

>>> nsum(lambda m,n: m**2*n/(3**m*(n*3**m+m*3**n)),
...     [1,inf], [1,inf])
0.28125
>>> mpf(9)/32
0.28125

>>> nsum(lambda i,j: fac(i-1)*fac(j-1)/fac(i+j),
...     [1,inf], [1,inf], workprec=400)
1.64493406684823
>>> zeta(2)
1.64493406684823
```

A hard example of a multidimensional sum is the Madelung constant in three dimensions (see MathWorld [1036]). The defining sum converges very slowly and only conditionally, so `nsum()` is lucky to obtain an accurate value through convergence acceleration. The second evaluation below uses a much more efficient, rapidly convergent 2D sum:

```
>>> nsum(lambda x,y,z: (-1)**(x+y+z)/(x*x+y*y+z*z)**0.5,
...     [-inf,inf], [-inf,inf], [-inf,inf], ignore=True)
-1.74756459463318
>>> nsum(lambda x,y: -12*pi*sech(0.5*pi * \
...     sqrt((2*x+1)**2+(2*y+1)**2))**2, [0,inf], [0,inf])
-1.74756459463318
```

Another example of a lattice sum in 2D:

```
>>> nsum(lambda x,y: (-1)**(x+y) / (x**2+y**2), [-inf,inf],
...     [-inf,inf], ignore=True)
-2.1775860903036
>>> -pi*ln2
-2.1775860903036
```

An example of an Eisenstein series:

```
>>> nsum(lambda m,n: (m+n*1j)**(-4), [-inf,inf], [-inf,inf],
...     ignore=True)
(3.1512120021539 + 0.0j)
```

5.13.2 Summation using the Euler-Maclaurin formula

ctx.sumem(*f*, *interval*, *tol=None*, *reject=10*, *integral=None*, *adiffs=None*, *bdiffs=None*, *verbose=False*, *error=False*, *_fast_abort=False*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Uses the Euler-Maclaurin formula to compute an approximation accurate to within `tol` (which defaults to the present epsilon) of the sum

$$S = \sum_{k=a}^{b} f(k)$$

where (a, b) are given by `interval` and a or b may be infinite. The approximation is

$$S \sim \int_a^b f(x)\,\mathrm{d}x + \frac{f(a)+f(b)}{2} + \sum_{k=1}^{\infty} \frac{B_{2k}}{(2k)!}\left(f^{(2k-1)}(b) - f^{(2k-1)}(a)\right).$$

The last sum in the Euler-Maclaurin formula is not generally convergent (a notable exception is if f is a polynomial, in which case Euler-Maclaurin actually gives an exact result).

The summation is stopped as soon as the quotient between two consecutive terms falls below *reject*. That is, by default (*reject* = 10), the summation is continued as long as each term adds at least one decimal.

Although not convergent, convergence to a given tolerance can often be "forced" if $b = \infty$ by summing up to $a + N$ and then applying the Euler-Maclaurin formula to the sum over the range $(a + N + 1, \ldots, \infty)$. This procedure is implemented by `nsum()`.

By default numerical quadrature and differentiation is used. If the symbolic values of the integral and endpoint derivatives are known, it is more efficient to pass the value of the integral explicitly as `integral` and the derivatives explicitly as `adiffs` and `bdiffs`. The derivatives should be given as iterables that yield $f(a), f'(a), f''(a), \ldots$ (and the equivalent for b).

Examples

Summation of an infinite series, with automatic and symbolic integral and derivative values (the second should be much faster):

```
>>> from xlcalcnet import *
>>> mp.dps = 50; mp.pretty = True
>>> sumem(lambda n: 1/n**2, [32, inf])
```

(continues on next page)

(continued from previous page)

```
0.031743366520302090126581680438741427141321886413417
>>> I = mpf(1)/32
>>> D = adiffs=((-1)**n*fac(n+1)*32**(-2-n) for n in range(999))
>>> sumem(lambda n: 1/n**2, [32, inf], integral=I, adiffs=D)
0.031743366520302090126581680438741427141321886413417
```

An exact evaluation of a finite polynomial sum:

```
>>> sumem(lambda n: n**5-12*n**2+3*n, [-100000, 200000])
10500155000624963999742499550000.0
>>> print(sum(n**5-12*n**2+3*n for n in range(-100000, 200001)))
10500155000624963999742499550000
```

5.13.3 Summation using the Abel-Plana formula

`ctx.`**`sumap`**(*f*, *interval*, *integral=None*, *error=False*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Evaluates an infinite series of an analytic summand f using the Abel-Plana formula

$$\sum_{k=0}^{\infty} f(k) = \int_0^{\infty} f(t)\mathrm{d}t + \frac{1}{2}f(0) + i\int_0^{\infty} \frac{f(it) - f(-it)}{e^{2\pi t} - 1}\mathrm{d}t.$$

Unlike the Euler-Maclaurin formula (see `sumem()`), the Abel-Plana formula does not require derivatives. However, it only works when $|f(it) - f(-it)|$ does not increase too rapidly with t.

Examples

The Abel-Plana formula is particularly useful when the summand decreases like a power of k; for example when the sum is a pure zeta function:

```
>>> from xlcalcnet import *
>>> mp.dps = 25; mp.pretty = True
>>> sumap(lambda k: 1/k**2.5, [1,inf])
1.3414872572509171797567 7
>>> zeta(2.5)
1.3414872572509171797567 7
>>> sumap(lambda k: 1/(k+1j)**(2.5+2.5j), [1,inf])
(-3.3853610685464733422860 84 - 0.7432082105196321803869551j)
>>> zeta(2.5+2.5j, 1+1j)
(-3.3853610685464733422860 84 - 0.7432082105196321803869551j)
```

If the series is alternating, numerical quadrature along the real line is likely to give poor results, so it is better to evaluate the first term symbolically whenever possible:

```
>>> n=3; z=-0.75
>>> I = expint(n,-log(z))
>>> chop(sumap(lambda k: z**k / k**n, [1,inf], integral=I))
-0.691703603690459451014144 8
>>> polylog(n,z)
-0.691703603690459451014144 8
```

5.13.4 Products

`ctx.`**`nprod`**(*f*, *interval*, *nsum=False*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Computes the product

$$P = \prod_{k=a}^{b} f(k)$$

where (a, b) = *interval*, and where $a = -\infty$ and/or $b = \infty$ are allowed.

By default, `nprod()` uses the same extrapolation methods as `nsum()`, except applied to the partial products rather than partial sums, and the same keyword options as for `nsum()` are supported. If `nsum=True`, the product is instead computed via `nsum()` as

$$P = \exp\left(\sum_{k=a}^{b} \log(f(k))\right).$$

This is slower, but can sometimes yield better results. It is also required (and used automatically) when Euler-Maclaurin summation is requested.

Examples

A simple finite product:

```
>>> from xlcalcnet import *
>>> mp.dps = 25; mp.pretty = True
>>> nprod(lambda k: k, [1, 4])
24.0
```

A large number of infinite products have known exact values, and can therefore be used as a reference. Most of the following examples are taken from MathWorld (see MathWorld [1034]).

A few infinite products with simple values are:

```
>>> 2*nprod(lambda k: (4*k**2)/(4*k**2-1), [1, inf])
3.1415926535897932384626433
>>> nprod(lambda k: (1+1/k)**2/(1+2/k), [1, inf])
2.0
>>> nprod(lambda k: (k**3-1)/(k**3+1), [2, inf])
0.66666666666666666666666667
>>> nprod(lambda k: (1-1/k**2), [2, inf])
0.5
```

Next, several more infinite products with more complicated values:

```
>>> nprod(lambda k: exp(1/k**2), [1, inf]); exp(pi**2/6)
5.1806683178971157484166260
5.1806683178971157484166260

>>> nprod(lambda k: (k**2-1)/(k**2+1), [2, inf]); pi*csch(pi)
0.27202905498213316295023660
0.27202905498213316295023660

>>> nprod(lambda k: (k**4-1)/(k**4+1), [2, inf])
0.84805404935290039212965020
>>> pi*sinh(pi)/(cosh(sqrt(2)*pi)-cos(sqrt(2)*pi))
0.84805404935290039212965020

>>> nprod(lambda k: (1+1/k+1/k**2)**2/(1+2/k+3/k**2), [1, inf])
1.8489361828582444852249270
>>> 3*sqrt(2)*cosh(pi*sqrt(3)/2)**2*csch(pi*sqrt(2))/pi
1.8489361828582444852249270

>>> nprod(lambda k: (1-1/k**4), [2, inf]); sinh(pi)/(4*pi)
0.91901947759374443017392440
0.91901947759374443017392440
```

(continues on next page)

(continued from previous page)

```
>>> nprod(lambda k: (1-1/k**6), [2, inf])
0.98268427774219251832447 59
>>> (1+cosh(pi*sqrt(3)))/(12*pi**2)
0.98268427774219251832447 59

>>> nprod(lambda k: (1+1/k**2), [2, inf]); sinh(pi)/(2*pi)
1.83803895518748886034784 9
1.83803895518748886034784 9

>>> nprod(lambda n: (1+1/n)**n * exp(1/(2*n)-1), [1, inf])
1.44725592689036529895913 8
>>> exp(1+euler/2)/sqrt(2*pi)
1.44725592689036529895913 8
```

The following two products are equivalent and can be evaluated in terms of a Jacobi theta function. Pi can be replaced by any value (as long as convergence is preserved):

```
>>> nprod(lambda k: (1-pi**-k)/(1+pi**-k), [1, inf])
0.38384512074816724047786 86
>>> nprod(lambda k: tanh(k*log(pi)/2), [1, inf])
0.38384512074816724047786 86
>>> jtheta(4,0,1/pi)
0.38384512074816724047786 86
```

This product does not have a known closed form value:

```
>>> nprod(lambda k: (1-1/2**k), [1, inf])
0.28878809508660242127889 97
```

A product taken from $-\infty$:

```
>>> nprod(lambda k: 1-k**(-3), [-inf,-2])
0.80939659736629010957868 05
>>> cosh(pi*sqrt(3)/2)/(3*pi)
0.80939659736629010957868 05
```

A doubly infinite product:

```
>>> nprod(lambda k: exp(1/(1+k**2)), [-inf, inf])
23.414326882318643374200 35
>>> exp(pi/tanh(pi))
23.414326882318643374200 35
```

A product requiring the use of Euler-Maclaurin summation to compute an accurate value:

```
>>> nprod(lambda k: (1-1/k**2.5), [2, inf], method='e')
0.69615511133623105289812 5
```

5.13.5 Limits, general

`ctx.`**`limit`**(*f*, *x*, *direction=1*, *exp=False*, ***kwargs*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Computes an estimate of the limit

$$\lim_{t \to x} f(t)$$

where x may be finite or infinite.

For finite x, `limit()` evaluates $f(x + d/n)$ for consecutive integer values of n, where the approach direction d may be specified using the *direction* keyword argument. For infinite x, `limit()` evaluates values of $f(\mathrm{sign}(x) \cdot n)$.

If the approach to the limit is not sufficiently fast to give an accurate estimate directly, `limit()` attempts to find the limit using Richardson extrapolation or the Shanks transformation. You can select between these methods using the *method* keyword (see documentation of `nsum()` for more information).

Options

The following options are available with essentially the same meaning as for `nsum()`: *tol*, *method*, *maxterms*, *steps*, *verbose*.

If the option *exp=True* is set, f will be sampled at exponentially spaced points $n = 2^1, 2^2, 2^3, \ldots$ instead of the linearly spaced points $n = 1, 2, 3, \ldots$. This can sometimes improve the rate of convergence so that `limit()` may return a more accurate answer (and faster). However, do note that this can only be used if f supports fast and accurate evaluation for arguments that are extremely close to the limit point (or if infinite, very large arguments).

Examples

A basic evaluation of a removable singularity:

```
>>> from xlcalcnet import *
>>> mp.dps = 30; mp.pretty = True
>>> limit(lambda x: (x-sin(x))/x**3, 0)
0.16666666666666666666666666667
```

Computing the exponential function using its limit definition:

```
>>> limit(lambda n: (1+3/n)**n, inf)
20.085536923187667740928529654
>>> exp(3)
20.085536923187667740928529654
```

A limit for π:

```
>>> f = lambda n: 2**(4*n+1)*fac(n)**4/(2*n+1)/fac(2*n)**2
>>> limit(f, inf)
3.1415926535897932384626433832
```

Calculating the coefficient in Stirling's formula:

```
>>> limit(lambda n: fac(n) / (sqrt(n)*(n/e)**n), inf)
2.5066282746310005024157652848
>>> sqrt(2*pi)
2.5066282746310005024157652848
```

Evaluating Euler's constant γ using the limit representation

$$\gamma = \lim_{n \to \infty} \left[\left(\sum_{k=1}^{n} \frac{1}{k} \right) - \log(n) \right]$$

(which converges notoriously slowly):

```
>>> f = lambda n: sum([mpf(1)/k for k in range(1,int(n)+1)]) - log(n)
>>> limit(f, inf)
0.57721566490153286060651209008
>>> +euler
0.57721566490153286060651209008
```

With default settings, the following limit converges too slowly to be evaluated accurately. Changing to exponential sampling however gives a perfect result:

```
>>> f = lambda x: sqrt(x**3+x**2)/(sqrt(x**3)+x)
>>> limit(f, inf)
0.99283115855833028112924968649
>>> limit(f, inf, exp=True)
1.0
```

5.13.6 Richardson extrapolation

`ctx.richardson`(*seq*)

where `ctx` is `dec`, `mpm`, or `gmp`.

See also: Wikipedia [1116] and C.M. and Orszag [169], pp. 375-376.

Given a list `seq` of the first N elements of a slowly convergent infinite sequence, `richardson()` computes the N-term Richardson extrapolate for the limit.

`richardson()` returns (v, c) where v is the estimated limit and c is the magnitude of the largest weight used during the computation. The weight provides an estimate of the precision lost to cancellation. Due to cancellation effects, the sequence must be typically be computed at a much higher precision than the target accuracy of the extrapolation.

Applicability and issues

Richardson extrapolation only works for a specific type of sequence, namely one converging like partial sums of $P(1)/Q(1) + P(2)/Q(2) + \ldots$ where P and Q are polynomials. When the sequence does not convergence at such a rate `richardson()` generally produces garbage.

Richardson extrapolation has the advantage of being fast: the N-term extrapolate requires only $O(N)$ arithmetic operations, and usually produces an estimate that is accurate to $O(N)$ digits. Contrast with the Shanks transformation (see `shanks()`), which requires $O(N^2)$ operations.

`richardson()` is unable to produce an estimate for the approximation error. One way to estimate the error is to perform two extrapolations with slightly different N and comparing the results.

Richardson extrapolation does not work for oscillating sequences. As a simple workaround, `richardson()` detects if the last three elements do not differ monotonically, and in that case applies extrapolation only to the even-index elements.

Examples

Applying Richardson extrapolation to the Leibniz series for π:

```
>>> from xlcalcnet import *
>>> mp.dps = 30; mp.pretty = True
>>> S = [4*sum(mpf(-1)**n/(2*n+1) for n in range(m))
...     for m in range(1,30)]
>>> v, c = richardson(S[:10])
>>> v
3.2126984126984126984126984127
>>> nprint([v-pi, c])
[0.0711058, 2.0]

>>> v, c = richardson(S[:30])
>>> v
3.1415926546862405282995420622 6
>>> nprint([v-pi, c])
[1.09645e-9, 20833.3]
```

5.13.7 Shanks extrapolation

`ctx.shanks`(*seq*, *table=None*, *randomized=False*)

where `ctx` is `dec`, `mpm`, or `gmp`.

See also: Wikipedia [1120], MathWorld [816].

Given a list `seq` of the first N elements of a slowly convergent infinite sequence (A_k), `shanks()` computes the iterated Shanks transformation $S(A), S(S(A)), \ldots, S^{N/2}(A)$. The Shanks transformation often provides strong convergence acceleration, especially if the sequence is oscillating.

The iterated Shanks transformation is computed using the Wynn epsilon algorithm (see [1]). `shanks()` returns the full epsilon table generated by Wynn's algorithm, which can be read off as follows:

- The table is a list of lists forming a lower triangular matrix, where higher row and column indices correspond to more accurate values.
- The columns with even index hold dummy entries (required for the computation) and the columns with odd index hold the actual extrapolates.
- The last element in the last row is typically the most accurate estimate of the limit.
- The difference to the third last element in the last row provides an estimate of the approximation error.
- The magnitude of the second last element provides an estimate of the numerical accuracy lost to cancellation.

For convenience, so the extrapolation is stopped at an odd index so that `shanks(seq)[-1][-1]` always gives an estimate of the limit.

Optionally, an existing table can be passed to `shanks()`. This can be used to efficiently extend a previous computation after new elements have been appended to the sequence. The table will then be updated in-place.

The Shanks transformation

The Shanks transformation is defined as follows (see C.M. and Orszag [169], pp. 368-375): given the input sequence $(A_0, A_1, \ldots)$, the transformed sequence is given by

$$S(A_k) = \frac{A_{k+1}A_{k-1} - A_k^2}{A_{k+1} + A_{k-1} - 2A_k}$$

The Shanks transformation gives the exact limit A_∞ in a single step if $A_k = A + aq^k$. Note in particular that it extrapolates the exact sum of a geometric series in a single step.

Applying the Shanks transformation once often improves convergence substantially for an arbitrary sequence, but the optimal effect is obtained by applying it iteratively: $S(S(A_k)), S(S(S(A_k))), \ldots$.

Wynn's epsilon algorithm provides an efficient way to generate the table of iterated Shanks transformations. It reduces the computation of each element to essentially a single division, at the cost of requiring dummy elements in the table. See Graves-Morris *et al.* [352] for details.

Precision issues

Due to cancellation effects, the sequence must be typically be computed at a much higher precision than the target accuracy of the extrapolation.

If the Shanks transformation converges to the exact limit (such as if the sequence is a geometric series), then a division by zero occurs. By default, `shanks()` handles this case by terminating the iteration and returning the table it has generated so far. With *randomized=True*, it will instead replace the zero by a pseudorandom number close to zero. (TODO: find a better solution to this problem.)

Examples

We illustrate by applying Shanks transformation to the Leibniz series for π:

```
>>> from xlcalcnet import *
>>> mp.dps = 50
>>> S = [4*sum(mpf(-1)**n/(2*n+1) for n in range(m))
...     for m in range(1,30)]
>>>
>>> T = shanks(S[:7])
>>> for row in T:
...     nprint(row)
...
[-0.75]
[1.25, 3.16667]
[-1.75, 3.13333, -28.75]
[2.25, 3.14524, 82.25, 3.14234]
[-2.75, 3.13968, -177.75, 3.14139, -969.937]
[3.25, 3.14271, 327.25, 3.14166, 3515.06, 3.14161]
```

The extrapolated accuracy is about 4 digits, and about 4 digits may have been lost due to cancellation:

```
>>> L = T[-1]
>>> nprint([abs(L[-1] - pi), abs(L[-1] - L[-3]), abs(L[-2])])
[2.22532e-5, 4.78309e-5, 3515.06]
```

Now we extend the computation:

```
>>> T = shanks(S[:25], T)
>>> L = T[-1]
>>> nprint([abs(L[-1] - pi), abs(L[-1] - L[-3]), abs(L[-2])])
[3.75527e-19, 1.48478e-19, 2.96014e+17]
```

The value for pi is now accurate to 18 digits. About 18 digits may also have been lost to cancellation.

Here is an example with a geometric series, where the convergence is immediate (the sum is exactly 1):

```
>>> mp.dps = 15
>>> for row in shanks([0.5, 0.75, 0.875, 0.9375, 0.96875]):
...     nprint(row)
[4.0]
[8.0, 1.0]
```

5.13.8 Levin extrapolation

`ctx.levin`(*seq*, *table=None*, *randomized=False*)

where `ctx` is `dec`, `mpm`, or `gmp`.

This interface implements Levin's (nonlinear) sequence transformation for convergence acceleration and summation of divergent series. It performs better than the Shanks/Wynn-epsilon algorithm for logarithmic convergent or alternating divergent series.

See also: Weniger [1080], Sidi [501], Homeier [374].

Let A be the series we want to sum:

$$A = \sum_{k=0}^{\infty} a_k$$

Attention: all a_k must be non-zero!

Let s_n be the partial sums of this series:

$$s_n = \sum_{k=0}^{n} a_k.$$

Methods

Calling `levin` returns an object with the following methods.

`update(...)` works with the list of individual terms a_k of A, and `update_step(...)` works with the list of partial sums s_k of A:

```
v, e = ...update([a_0, a_1,..., a_k])
v, e = ...update_psum([s_0, s_1,..., s_k])
```

`step(...)` works with the individual terms a_k and `step_psum(...)` works with the partial sums s_k:

```
v, e = ...step(a_k)
v, e = ...step_psum(s_k)
```

v is the current estimate for A, and e is an error estimate which is simply the difference between the current estimate and the last estimate. One should not mix `update`, `update_psum`, `step` and `step_psum`.

A word of caution

One can only hope for good results (i.e. convergence acceleration or resummation) if the s_n have some well defind asymptotic behavior for large n and are not erratic or random. Furthermore one usually needs very high working precision because of the numerical cancellation. If the working precision is insufficient, levin may produce silently numerical garbage. Furthermore even if the Levin-transformation converges, in the general case there is no proof that the result is mathematically sound. Only for very special classes of problems one can prove that the Levin-transformation converges to the expected result (for example Stieltjes-type integrals). Furthermore the Levin-transform is quite expensive (i.e. slow) in comparison to Shanks/Wynn-epsilon, Richardson & co. In summary one can say that the Levin-transformation is powerful but unreliable and that it may need a copious amount of working precision.

The Levin transform has several variants differing in the choice of weights. Some variants are better suited for the possible flavours of convergence behaviour of A than other variants:

```
convergence behaviour   levin-u   levin-t   levin-v   shanks/wynn-epsilon

logarithmic               +         -         +           -
linear                    +         +         +           +
alternating divergent     +         +         +           +

    "+" means the variant is suitable,"-" means the variant is not suitable;
    for comparison the Shanks/Wynn-epsilon transform is listed, too.
```

The variant is controlled though the variant keyword (i.e. `variant="u"`, `variant="t"` or `variant="v"`). Overall "u" is probably the best choice.

Finally it is possible to use the Sidi-S transform instead of the Levin transform by using the keyword `method='sidi'`. The Sidi-S transform works better than the Levin transformation for some divergent series (see the examples).

Parameters:

```
method      "levin" or "sidi" chooses either the Levin or the Sidi-S transformation
variant     "u","t" or "v" chooses the weight variant.
```

The Levin transform is also accessible through the nsum interface. `method="l"` or `method="levin"` select the normal Levin transform while `method="sidi"` selects the Sidi-S transform. The variant is in both cases selected through the levin_variant keyword. The stepsize in `nsum()` must not be chosen too large, otherwise it will miss the point where the Levin transform converges resulting in numerical overflow/garbage. For highly divergent series a copious amount of working precision must be chosen.

Examples

First we sum the zeta function:

```
>>> from mpmath import mp
>>> mp.prec = 53
>>> eps = mp.mpf(mp.eps)
>>> with mp.extraprec(2 * mp.prec): # levin needs a high working precision
...     L = mp.levin(method = "levin", variant = "u")
...     S, s, n = [], 0, 1
...     while 1:
...         s += mp.one / (n * n)
...         n += 1
...         S.append(s)
...         v, e = L.update_psum(S)
...         if e < eps:
...             break
...         if n > 1000: raise RuntimeError("iteration limit exceeded")
>>> print(mp.chop(v - mp.pi ** 2 / 6))
0.0
```

(continues on next page)

(continued from previous page)

```
>>> w = mp.nsum(lambda n: 1 / (n*n), [1, mp.inf], method = "levin", levin_variant = "u")
>>> print(mp.chop(v - w))
0.0
```

Now we sum the zeta function outside its range of convergence (attention: This does not work at the negative integers!):

```
>>> eps = mp.mpf(mp.eps)
>>> with mp.extraprec(2 * mp.prec): # levin needs a high working precision
...     L = mp.levin(method = "levin", variant = "v")
...     A, n = [], 1
...     while 1:
...         s = mp.mpf(n) ** (2 + 3j)
...         n += 1
...         A.append(s)
...         v, e = L.update(A)
...         if e < eps:
...             break
...         if n > 1000: raise RuntimeError("iteration limit exceeded")
>>> print(mp.chop(v - mp.zeta(-2-3j)))
0.0
>>> w = mp.nsum(lambda n: n ** (2 + 3j), [1, mp.inf], method = "levin", levin_variant = "v")
>>> print(mp.chop(v - w))
0.0
```

Now we sum the divergent asymptotic expansion of an integral related to the exponential integral (see also Sidi [501] p.373). The Sidi-S transform works best here:

```
>>> z = mp.mpf(10)
>>> exact = mp.quad(lambda x: mp.exp(-x)/(1+x/z),[0,mp.inf])
>>> # exact = z * mp.exp(z) * mp.expint(1,z) # this is the symbolic expression for the integral
>>> eps = mp.mpf(mp.eps)
>>> with mp.extraprec(2 * mp.prec): # high working precisions are mandatory for divergent resummation
...     L = mp.levin(method = "sidi", variant = "t")
...     n = 0
...     while 1:
...         s = (-1)**n * mp.fac(n) * z ** (-n)
...         v, e = L.step(s)
...         n += 1
...         if e < eps:
...             break
...         if n > 1000: raise RuntimeError("iteration limit exceeded")
>>> print(mp.chop(v - exact))
0.0
>>> w = mp.nsum(lambda n: (-1) ** n * mp.fac(n) * z ** (-n), [0, mp.inf], \
...   method = "sidi", levin_variant = "t")
>>> print(mp.chop(v - w))
0.0
```

Another highly divergent integral is also summable:

```
>>> z = mp.mpf(2)
>>> eps = mp.mpf(mp.eps)
>>> exact = mp.quad(lambda x: mp.exp( -x * x / 2 - z * x ** 4), [0,mp.inf]) * 2 / mp.sqrt(2 * mp.pi)
>>> # exact = mp.exp(mp.one / (32 * z)) * mp.besselk(mp.one / 4, mp.one / (32 * z))
>>> # / (4 * mp.sqrt(z * mp.pi)) # this is the symbolic expression for the integral
>>> with mp.extraprec(7 * mp.prec):
>>> # we need copious amount of precision to sum this highly divergent series
...     L = mp.levin(method = "levin", variant = "t")
...     n, s = 0, 0
...     while 1:
...         s += (-z)**n * mp.fac(4 * n) / (mp.fac(n) * mp.fac(2 * n) * (4 ** n))
...         n += 1
...         v, e = L.step_psum(s)
...         if e < eps:
```

(continues on next page)

(continued from previous page)

```
...             break
...         if n > 1000: raise RuntimeError("iteration limit exceeded")
>>> print(mp.chop(v - exact))
0.0
>>> w = mp.nsum(lambda n: (-z)**n * mp.fac(4 * n) / (mp.fac(n) * mp.fac(2 * n) * (4 ** n)),
...   [0, mp.inf], method = "levin", levin_variant = "t", workprec = 8*mp.prec, \
...   steps = [2] + [1 for x in xrange(1000)])
>>> print(mp.chop(v - w))
0.0
```

These examples run with 15-20 decimal digits precision. For higher precision the working precision must be raised.

Examples for nsum

Here we calculate Euler's constant as the constant term in the Laurent expansion of $\zeta(s)$ at $s = 1$. This sum converges extremly slowly because of the logarithmic convergence behaviour of the Dirichlet series for zeta:

```
>>> mp.dps = 30
>>> z = mp.mpf(10) ** (-10)
>>> a = mp.nsum(lambda n: n**(-(1+z)), [1, mp.inf], method = "l") - 1 / z
>>> print(mp.chop(a - mp.euler, tol = 1e-10))
0.0
```

The Sidi-S transform performs excellently for the alternating series of $\log(2)$:

```
>>> a = mp.nsum(lambda n: (-1)**(n-1) / n, [1, mp.inf], method = "sidi")
>>> print(mp.chop(a - mp.log(2)))
0.0
```

Hypergeometric series can also be summed outside their range of convergence. The stepsize in `nsum()` must not be chosen too large, otherwise it will miss the point where the Levin transform converges resulting in numerical overflow/garbage:

```
>>> z = 2 + 1j
>>> exact = mp.hyp2f1(2 / mp.mpf(3), 4 / mp.mpf(3), 1 / mp.mpf(3), z)
>>> f = lambda n: mp.rf(2 / mp.mpf(3), n) * mp.rf(4 / mp.mpf(3), n) * z**n \
...   / (mp.rf(1 / mp.mpf(3), n) * mp.fac(n))
>>> v = mp.nsum(f, [0, mp.inf], method = "levin", steps = [10 for x in xrange(1000)])
>>> print(mp.chop(exact-v))
0.0
```

5.13.9 Cohan alternating extrapolation

`ctx.cohen_alt`(*seq*, *table=None*, *randomized=False*)

where `ctx` is `dec`, `mpm`, or `gmp`.

This interface implements the convergence acceleration of alternating series as described in Cohen *et al.* [182].

This series transformation works only well if the individual terms of the series have an alternating sign. It belongs to the class of linear series transformations (in contrast to the Shanks/Wynn-epsilon or Levin transform). This series transformation is also able to sum some types of divergent series. See the paper under which conditions this resummation is mathematical sound.

Let A be the series we want to sum:

$$A = \sum_{k=0}^{\infty} a_k$$

Let s_n be the partial sums of this series:

$$s_n = \sum_{k=0}^{n} a_k.$$

Interface

Calling `cohen_alt` returns an object with the following methods.

Then `update(...)` works with the list of individual terms a_k and `update_psum(...)` works with the list of partial sums s_k:

```
v, e = ...update([a_0, a_1,..., a_k])
v, e = ...update_psum([s_0, s_1,..., s_k])
```

v is the current estimate for A, and e is an error estimate which is simply the difference between the current estimate and the last estimate.

Examples

Here we compute the alternating zeta function using `update_psum`:

```
>>> from mpmath import mp
>>> AC = mp.cohen_alt()
>>> S, s, n = [], 0, 1
>>> while 1:
...     s += -((-1) ** n) * mp.one / (n * n)
...     n += 1
...     S.append(s)
...     v, e = AC.update_psum(S)
...     if e < mp.eps:
...         break
...     if n > 1000: raise RuntimeError("iteration limit exceeded")
>>> print(mp.chop(v - mp.pi ** 2 / 12))
0.0
```

Here we compute the product $\prod_{n=1}^{\infty} \Gamma(1+1/(2n-1))/\Gamma(1+1/(2n))$:

```
>>> A = []
>>> AC = mp.cohen_alt()
>>> n = 1
>>> while 1:
...     A.append( mp.loggamma(1 + mp.one / (2 * n - 1)))
...     A.append(-mp.loggamma(1 + mp.one / (2 * n)))
...     n += 1
...     v, e = AC.update(A)
...     if e < mp.eps:
...         break
...     if n > 1000: raise RuntimeError("iteration limit exceeded")
>>> v = mp.exp(v)
>>> print(mp.chop(v - 1.06215090557106, tol = 1e-12))
0.0
```

`cohen_alt` is also accessible through the `nsum()` interface:

```
>>> v = mp.nsum(lambda n: (-1)**(n-1) / n, [1, mp.inf], method = "a")
>>> print(mp.chop(v - mp.log(2)))
0.0
>>> v = mp.nsum(lambda n: (-1)**n / (2 * n + 1), [0, mp.inf], method = "a")
>>> print(mp.chop(v - mp.pi / 4))
0.0
>>> v = mp.nsum(lambda n: (-1)**n * mp.log(n) * n, [1, mp.inf], method = "a")
>>> print(mp.chop(v - mp.diff(lambda s: mp.altzeta(s), -1)))
0.0
```

5.14 Mpmath: Polynomials

Python code for `gmp` and `dec` is available in `Test_Python.numpy.py`.

5.14.1 Polynomial evaluation

`ctx.polyval`(*coeffs*, *x*, *derivative=False*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Given coefficients $[c_n, \ldots, c_2, c_1, c_0]$ and a number x, `polyval()` evaluates the polynomial

$$P(x) = c_n x^n + \ldots + c_2 x^2 + c_1 x + c_0.$$

If *derivative=True* is set, `polyval()` simultaneously evaluates $P(x)$ with the derivative, $P'(x)$, and returns the tuple $(P(x), P'(x))$.

```
>>> from xlcalcnet import *
>>> mp.pretty = True
>>> polyval([3, 0, 2], 0.5)
2.75
>>> polyval([3, 0, 2], 0.5, derivative=True)
(2.75, 3.0)
```

The coefficients and the evaluation point may be any combination of real or complex numbers.

5.14.2 Polynomial roots

`ctx.polyroots`(*coeffs*, *maxsteps=50*, *cleanup=True*, *extraprec=10*, *error=False*, *roots_init=None*)

where `ctx` is `dec`, `mpm`, or `gmp`.

Computes all roots (real or complex) of a given polynomial.

The roots are returned as a sorted list, where real roots appear first followed by complex conjugate roots as adjacent elements. The polynomial should be given as a list of coefficients, in the format used by `polyval()`. The leading coefficient must be nonzero.

With *error=True*, `polyroots()` returns a tuple *(roots, err)* where *err* is an estimate of the maximum error among the computed roots.

Examples

Finding the three real roots of $x^3 - x^2 - 14x + 24$:

```
>>> from xlcalcnet import *
>>> mp.dps = 15; mp.pretty = True
>>> nprint(polyroots([1,-1,-14,24]), 4)
[-4.0, 2.0, 3.0]
```

Finding the two complex conjugate roots of $4x^2 + 3x + 2$, with an error estimate:

```
>>> roots, err = polyroots([4,3,2], error=True)
>>> for r in roots:
...     print(r)
...
(-0.375 + 0.599478940414 09j)
(-0.375 - 0.599478940414 09j)
>>>
>>> err
2.22044604925031e-16
>>>
>>> polyval([4,3,2], roots[0])
(2.22044604925031e-16 + 0.0j)
>>> polyval([4,3,2], roots[1])
(2.22044604925031e-16 + 0.0j)
```

The following example computes all the 5th roots of unity; that is, the roots of $x^5 - 1$:

```
>>> mp.dps = 20
>>> for r in polyroots([1, 0, 0, 0, 0, -1]):
...     print(r)
...
1.0
(-0.8090169943749474241 + 0.58778525229247312917j)
(-0.8090169943749474241 - 0.58778525229247312917j)
(0.3090169943749474241 + 0.95105651629515357212j)
(0.3090169943749474241 - 0.95105651629515357212j)
```

Precision and conditioning

The roots are computed to the current working precision accuracy. If this accuracy cannot be achieved in `maxsteps` steps, then a `NoConvergence` exception is raised. The algorithm internally is using the current working precision extended by `extraprec`. If `NoConvergence` was raised, that is caused either by not having enough extra precision to achieve convergence (in which case increasing `extraprec` should fix the problem) or too low `maxsteps` (in which case increasing `maxsteps` should fix the problem), or a combination of both.

The user should always do a convergence study with regards to `extraprec` to ensure accurate results. It is possible to get convergence to a wrong answer with too low `extraprec`.

Provided there are no repeated roots, `polyroots()` can typically compute all roots of an arbitrary polynomial to high precision:

```
>>> mp.dps = 60
>>> for r in polyroots([1, 0, -10, 0, 1]):
...     print(r)
...
-3.14626436994197234232913506571557044551247712918732870123249
-0.31783724519578224472575761729617428837313337843343255487912 7
0.31783724519578224472575761729617428837313337843343255487912 7
3.14626436994197234232913506571557044551247712918732870123249
>>>
>>> sqrt(3) + sqrt(2)
3.14626436994197234232913506571557044551247712918732870123249
>>> sqrt(3) - sqrt(2)
0.31783724519578224472575761729617428837313337843343255487912 7
```

Algorithm

`polyroots()` implements the Durand-Kerner method (see Wikipedia [1091]), which uses complex arithmetic to locate all roots simultaneously. The Durand-Kerner method can be viewed as approximately performing simultaneous Newton iteration for all the roots. In particular, the convergence to simple roots is quadratic, just like Newton's method.

Although all roots are internally calculated using complex arithmetic, any root found to have an imaginary part smaller than the estimated numerical error is truncated to a real number (small real parts are also chopped). Real roots are placed first in the returned list, sorted by value. The remaining complex roots are sorted by their real parts so that conjugate roots end up next to each other.

5.15 Eigen/MinPack: non linear optimization

5.15.1 Multidimensional Rootfinding: Powell Hybrid

ctxboost.**PowellHybrid**(*f*, *fjac*, *guess*)

This is a modified version of Powell's Hybrid method as implemented in the hybrj algorithm in minpack. The Hybrid algorithm retains the fast convergence of Newton's method but will also reduce the residual when Newton's method is unreliable. The algorithm uses a generalized trust region to keep each step under control.

See also: Moré *et al.* [417], Eigen [216], Wikipedia [1435], Powell [474].

Parameters:

f
a callback matrix function defining the system.

fjac
a callback matrix function defining the Jacobian of the system system.

guess
a matrix containing the initial guess for the solution

Results:

x1
a matrix containing the solution.

Example:

This is an example from the original manual of MINPACK (Moré *et al.* [417]).

The routine in Python:

```
def demo_PowellHybridCtx(ctx):

    # The function to optimize
    def XmatHybrd(x, fvec):
        n = x.size
        for k in range(n):
            temp = (3.0 - 2.0 * x[k]) * x[k]
            temp1 = ctx.zero()
            if (k!=0): temp1 = x[k-1]
            temp2 = ctx.zero()
            if (k != n-1): temp2 = x[k+1]
            fvec[k] = temp - temp1 - 2.0*temp2 + 1.0

    # The Jacobi function
    def XmatHybrdJ(x, fjac):
        n = x.size
        for k in range(n):
            for j in range(n):
                fjac[k, j] = ctx.zero()
            fjac[k, k] = 3.0 - 4.0 * x[k]
            if (k != 0): fjac[k, k - 1] = -1
            if (k != n - 1): fjac[k, k + 1] = -2

    # This defines the start vector
    n = 9
    matInput = ctx.matZeros(n,1)
    matInput[0] = 1
    matInput[1] = 2  # entries 2 .. 8 are 0.
    print('matInput: \n', matInput)

    # This executes the PowellHybrd solver
    matRes = ctx.powellHybrd(XmatHybrd, XmatHybrdJ, matInput)
```

(continues on next page)

(continued from previous page)

```
    # Check the result
    Y = ctx.matZeros(n,1)
    XmatHybrd(matRes, Y)
    print('matRes: \n', matRes)
    print('Y: \n', Y)
```

The output of these routines:

```
Hello DemoPowellHybrdClassDbl()

X (solution):
-0.570654511600659,

```

5.15.2 Nonlinear LeastSquares: Levenberg-Marquardt

`ctxboost.Levenberg`(*f*, *fjac*, *matInput*)

This is a robust and efficient version of the Levenberg-Marquardt algorithm as implemented in the scaled lmder routine in minpack. The algorithm uses a generalized trust region to keep each step under control.

See also: Moré *et al.* [417], Eigen [216], Wikipedia [1429].

Parameters:

f
a callback matrix function defining the system.

fjac
a callback matrix function defining the Jacobian of the system system.

guess
a matrix containing the initial guess for the solution

Results:

x1
a matrix containing the solution.

Example:

This is an example from the original manual of MINPACK (Moré *et al.* [417]).

The routine in Python:

```
def demo_LevenbergCtx(ctx):

    # The function to optimize
    def XmatLM(x, fvec):
        m = 15
        y = ctx.matZeros(m,1)
        y[0] = 1.4e-1
        y[1] = 1.8e-1
        y[2] = 2.2e-1
        y[3] = 2.5e-1

5.16 Eigen/CppOptLib: multidimensional optimization

The Homepage is https://github.com/PatWie/CppNumericalSolvers.

To use another solver, simply replace BfgsSolver by another name. Supported solvers are:

gradient descent solver (GradientDescentSolver)

conjugate gradient descent solver (ConjugatedGradientDescentSolver)

BFGS solver (BfgsSolver)

L-BFGS solver (LbfgsSolver) bfgsbSolver)

CMAes solver (CMAesSolver)

Nelder-Mead solver (NelderMeadSolver)

These solvers are tested on the Rosenbrock function from multiple difficult starting points by unit tests using the Google Testing Framework. And yes, you can use them directly in MATLAB. Additional benchmark functions are Beale, GoldsteinPrice, Booth, Matyas, Levi. Note, not all solvers are equivalently good at all problems.

For checking your gradient this library uses high-order central difference. Study the examples for more information about including box-constraints and gradient-information.

5.16.1 Nelder-Mead Solver

ctxboost.**NelderMead**(*f*, *fjac*, *matInput*)

The Nelder-Mead method (or downhill simplex method) is a commonly applied numerical method used to find the minimum or maximum of an objective function in a multidimensional space.

See also: Wieschollek [1083], Wikipedia [1434].

Parameters:

f
a callback matrix function defining the system.

fjac
a callback matrix function defining the Jacobian of the system system.

guess
a matrix containing the initial guess for the solution

Results:

x1
a matrix containing the solution.

Example:

The routine in Python:

```
def demo_NelderMeadCtx(ctx):

    # The function to optimize
    def matF1(X, Y):
        t1 = 1 - X[0]
        t2 = X[1] - X[0] * X[0]
        Y[0] = t1 * t1 + 100 * t2 * t2

    # The Jacobi function
    def matF2(X, Y):
        Y[0] = -2 * (1 - X[0]) + 200 * (X[1] - X[0] * X[0]) * (-2 * X[0])
        Y[1] = 200 * (X[1] - X[0] * X[0])

    # This defines the start vector
    r = 2
    c = 1
    X = ctx.matZeros(r,c)
    X[0] = 1
    X[1] = 2
    print('X: \n', X)

    # This executes the NelderMead solver
    matRes = ctx.nelderMeadSolver(matF1, matF2, X)

    # Check the result
    Y = ctx.matZeros(r,c)
    matF1(matRes, Y)
    print('matRes: \n', matRes)
    print('Y: \n', Y)
    nrm = ctx.sqrt( Y[0]*Y[0] + Y[1]*Y[1]) # result is correct
    print('Norm: \n', nrm)
```

This produces the following output:

```
Hello DemoNelderMeadSolverDbl()
matRes:
    1.000014;
```

(continues on next page)

(continued from previous page)

```
    1.000029;

Y = F(matRes):
    0.000000;
    0.000000;

Norm: 2.96378497762668E-10
```

5.16.2 CMAes solver

`ctxboost.CMAes`(*f*, *fjac*, *matInput*)

CMA-ES stands for covariance matrix adaptation evolution strategy. Evolution strategies (ES) are stochastic, derivative-free methods for numerical optimization of non-linear or non-convex continuous optimization problems.

See also: Wieschollek [1083], Wikipedia [1425].

Parameters:

f
a callback matrix function defining the system.

fjac
a callback matrix function defining the Jacobian of the system system.

guess
a matrix containing the initial guess for the solution

Results:

x1
a matrix containing the solution.

Example:

The routine in Python:

```
def demo_CMAesCtx(ctx):

    # The function to optimize
    def matF1(X, Y):
        t1 = 1 - X[0]
        t2 = X[1] - X[0] * X[0]
        Y[0] = t1 * t1 + 100 * t2 * t2

    # The Jacobi function
    def matF2(X, Y):
        Y[0] = -2 * (1 - X[0]) + 200 * (X[1] - X[0] * X[0]) * (-2 * X[0])
        Y[1] = 200 * (X[1] - X[0] * X[0])

    # This defines the start vector
    r = 2
    c = 1
    X = ctx.matZeros(r,c)
    X[0] = 1
    X[1] = 2
    print('X: \n', X)

    # This executes the CMAes solver
    matRes = ctx.cMAesSolver(matF1, matF2, X)

    # Check the result
    Y = ctx.matZeros(r,c)
    matF1(matRes, Y)
    print('matRes: \n', matRes)
    print('Y: \n', Y)
    nrm = ctx.sqrt( Y[0]*Y[0] + Y[1]*Y[1]) # result is correct
    print('Norm: \n', nrm)
```

This produces the following output:

```
Hello DemoCMAesSolverDbl()
matRes:
    0.999140;
```

(continues on next page)

(continued from previous page)

```
    0.998260;

Y = F(matRes):
    0.000001;
    0.000000;

Norm: 7.83903245823684E-07
```

5.16.3 BFGS Solver

`ctxboost.BFGS`(*f*, *fjac*, *matInput*)

The Broyden-Fletcher-Goldfarb-Shanno (BFGS) algorithm is an iterative method for solving unconstrained nonlinear optimization problems.

See also: Wieschollek [1083], Wikipedia [1424].

Parameters:

f
a callback matrix function defining the system.

fjac
a callback matrix function defining the Jacobian of the system system.

guess
a matrix containing the initial guess for the solution

Results:

x1
a matrix containing the solution.

Example:

The routine in Python:

```
def demo_BfgsCtx(ctx):

    # The function to optimize
    def matF1(X, Y):
        t1 = 1 - X[0]
        t2 = X[1] - X[0] * X[0]
        Y[0] = t1 * t1 + 100 * t2 * t2

    # The Jacobi function
    def matF2(X, Y):
        Y[0] = -2 * (1 - X[0]) + 200 * (X[1] - X[0] * X[0]) * (-2 * X[0])
        Y[1] = 200 * (X[1] - X[0] * X[0])

    # This defines the start vector
    r = 2
    c = 1
    X = ctx.matZeros(r,c)
    X[0] = 1
    X[1] = 2
    print('X: \n', X)

    # This executes the Bfgs solver
    matRes = ctx.bfgsSolver(matF1, matF2, X)

    # Check the result
    Y = ctx.matZeros(r,c)
    matF1(matRes, Y)
    print('matRes: \n', matRes)
    print('Y: \n', Y)
    nrm = ctx.sqrt( Y[0]*Y[0] + Y[1]*Y[1]) # result is correct
    print('Norm: \n', nrm)
```

This produces the following output:

```
Hello DemoBfgsSolverClassDbl()
matRes:
0.999999951430365,
```

(continues on next page)

(continued from previous page)

```
0.999999899650162,

Y = F(matRes):
3.389785983959666E-15,
0,

Norm: 3.389785983959666E-15
```

5.16.4 L-BFGS Solver

ctxboost.**LBFGS**(*f*, *fjac*, *matInput*)

Limited-memory BFGS (L-BFGS or LM-BFGS) is an optimization algorithm in the family of quasi-Newton methods that approximates the Broyden-Fletcher-Goldfarb-Shanno algorithm (BFGS) using a limited amount of computer memory.

See also: Wieschollek [1083], Wikipedia [1430].

Parameters:

f
a callback matrix function defining the system.

fjac
a callback matrix function defining the Jacobian of the system system.

guess
a matrix containing the initial guess for the solution

Results:

x1
a matrix containing the solution.

Example:

The routine in Python:

```
def demo_LBfgsCtx(ctx):

    # The function to optimize
    def matF1(X, Y):
        t1 = 1 - X[0]
        t2 = X[1] - X[0] * X[0]
        Y[0] = t1 * t1 + 100 * t2 * t2

    # The Jacobi function
    def matF2(X, Y):
        Y[0] = -2 * (1 - X[0]) + 200 * (X[1] - X[0] * X[0]) * (-2 * X[0])
        Y[1] = 200 * (X[1] - X[0] * X[0])

    # This defines the start vector
    r = 2
    c = 1
    X = ctx.matZeros(r,c)
    X[0] = 1
    X[1] = 2
    print('X: \n', X)

    # This executes the LBfgs solver
    matRes = ctx.lbfgsBSolver(matF1, matF2, X)

    # Check the result
    Y = ctx.matZeros(r,c)
    matF1(matRes, Y)
    print('matRes: \n', matRes)
    print('Y: \n', Y)
    nrm = ctx.sqrt( Y[0]*Y[0] + Y[1]*Y[1]) # result is correct
    print('Norm: \n', nrm)
```

This produces the following output:

```
Hello DemoLbfgsSolverDbl()
matRes:
    1.000000;
```

(continues on next page)

(continued from previous page)

```
    1.000000;

Y = F(matRes):
    0.000000;
    0.000000;

Norm: 7.41089272169439E-14
```

5.16.5 Gradient descent solver

`ctxboost.GradientDescent`(*f*, *fjac*, *matInput*)

Gradient descent is a first-order iterative optimization algorithm for finding a local minimum of a differentiable function.

See also: Wieschollek [1083], Wikipedia [1424]. and https://en.wikipedia.org/wiki/Gradient_descent.

Parameters:

f
a callback matrix function defining the system.

fjac
a callback matrix function defining the Jacobian of the system system.

guess
a matrix containing the initial guess for the solution

Results:

x1
a matrix containing the solution.

Example:

The routine in Python:

```
def demo_GradientDescentCtx(ctx):

    # The function to optimize
    def matF1(X, Y):
        t1 = 1 - X[0]
        t2 = X[1] - X[0] * X[0]
        Y[0] = t1 * t1 + 100 * t2 * t2

    # The Jacobi function
    def matF2(X, Y):
        Y[0] = -2 * (1 - X[0]) + 200 * (X[1] - X[0] * X[0]) * (-2 * X[0])
        Y[1] = 200 * (X[1] - X[0] * X[0])

    # This defines the start vector
    r = 2
    c = 1
    X = ctx.matZeros(r,c)
    X[0] = 1
    X[1] = 2
    print('X: \n', X)

    # This executes the GradientDescentSolver solver
    matRes = ctx.gradientDescentSolver(matF1, matF2, X)

    # Check the result
    Y = ctx.matZeros(r,c)
    matF1(matRes, Y)
    print('matRes: \n', matRes)
    print('Y: \n', Y)
    nrm = ctx.sqrt( Y[0]*Y[0] + Y[1]*Y[1]) # result is correct
    print('Norm: \n', nrm)
```

This produces the following output:

```
Hello DemoBfgsSolverClassDbl()
matRes:
0.999999951430365,
0.999999899650162,
```

(continues on next page)

(continued from previous page)

```
Y = F(matRes):
3.38978598395966E-15,
0,

Norm: 3.38978598395966E-15
```

5.16.6 Conjugate gradient descent solver

`ctxboost.ConjugateGradientDescent`(*f*, *fjac*, *matInput*)

The conjugate gradient method is an algorithm for the numerical solution of particular systems of linear equations, namely those whose matrix is symmetric and positive-definite. The conjugate gradient method can also be used to solve unconstrained optimization problems such as energy minimization.

See also: Wieschollek [1083], Wikipedia [1424]. and https://en.wikipedia.org/wiki/Conjugate_gradient_method.

Parameters:

f
a callback matrix function defining the system.

fjac
a callback matrix function defining the Jacobian of the system system.

guess
a matrix containing the initial guess for the solution

Results:

x1
a matrix containing the solution.

Example:

The routine in Python:

```
def demo_GradientDescentCtx(ctx):

    # The function to optimize
    def matF1(X, Y):
        t1 = 1 - X[0]
        t2 = X[1] - X[0] * X[0]
        Y[0] = t1 * t1 + 100 * t2 * t2

    # The Jacobi function
    def matF2(X, Y):
        Y[0] = -2 * (1 - X[0]) + 200 * (X[1] - X[0] * X[0]) * (-2 * X[0])
        Y[1] = 200 * (X[1] - X[0] * X[0])

    # This defines the start vector
    r = 2
    c = 1
    X = ctx.matZeros(r,c)
    X[0] = 1
    X[1] = 2
    print('X: \n', X)

    # This executes the GradientDescentSolver solver
    matRes = ctx.gradientDescentSolver(matF1, matF2, X)

    # Check the result
    Y = ctx.matZeros(r,c)
    matF1(matRes, Y)
    print('matRes: \n', matRes)
    print('Y: \n', Y)
    nrm = ctx.sqrt( Y[0]*Y[0] + Y[1]*Y[1]) # result is correct
    print('Norm: \n', nrm)
```

Example:

```
Public Sub matF1(x As dbl_mat_t, y As dbl_mat_t)
    Dim t1 As Double = 1 - x(0)
```

(continues on next page)

(continued from previous page)

```
    Dim t2 As Double = x(1) - x(0) * x(0)
    y(0) = t1 * t1 + 100 * t2 * t2
End Sub

Public Sub matF2(x As dbl_mat_t, y As dbl_mat_t)
    y(0) = -2 * (1 - x(0)) + 200 * (x(1) - x(0) * x(0)) * (-2 * x(0))
    y(1) = 200 * (x(1) - x(0) * x(0))
End Sub

Sub DemoConjugatedGradientDescentSolverDbl()
    Console.WriteLine("Hello DemoConjugatedGradientDescentSolverDbl() ")
    Dim X, Y As New dbl_mat_t()
    X.resize(2, 1)
    Y.resize(X.rows, 1)
    X(0) = 1
    X(1) = 2

    Dim OptLib As New ConjugatedGradientDescentSolverDbl(AddressOf matF1, AddressOf matF2, X)
    Dim matRes = OptLib.Solve()
    matRes.print("matRes: ", 15)
    matF1(matRes, Y)
    Y.print("Y = F(matRes): ", 15)

    Dim nrm = Math.Sqrt( Y(0)*Y(0) + Y(1)*Y(1))
    Console.WriteLine("Norm: {0}", nrm)
    Console.WriteLine("")
End Sub
```

This produces the following output:

```
Hello DemoConjugatedGradientDescentSolverDbl()
matRes:
    0.999964;
    0.999928;

Y = F(matRes):
    0.000000;
    0.000000;

Norm: 1.3055097726625E-09
```

5.16.7 Newton descent solver (description needs correction)

ctxboost.**NewtonDescent**(*f*, *fjac*, *matInput*)

The conjugate gradient method is an algorithm for the numerical solution of particular systems of linear equations, namely those whose matrix is symmetric and positive-definite. The conjugate gradient method can also be used to solve unconstrained optimization problems such as energy minimization.

See also: Wieschollek [1083], Wikipedia [1424]. and https://en.wikipedia.org/wiki/Conjugate_gradient_method.

Parameters:

f
a callback matrix function defining the system.

fjac
a callback matrix function defining the Jacobian of the system system.

guess
a matrix containing the initial guess for the solution

Results:

x1
a matrix containing the solution.

Example:

The routine in Python:

```
def demo_GradientDescentCtx(ctx):

    # The function to optimize
    def matF1(X, Y):
        t1 = 1 - X[0]
        t2 = X[1] - X[0] * X[0]
        Y[0] = t1 * t1 + 100 * t2 * t2

    # The Jacobi function
    def matF2(X, Y):
        Y[0] = -2 * (1 - X[0]) + 200 * (X[1] - X[0] * X[0]) * (-2 * X[0])
        Y[1] = 200 * (X[1] - X[0] * X[0])

    # This defines the start vector
    r = 2
    c = 1
    X = ctx.matZeros(r,c)
    X[0] = 1
    X[1] = 2
    print('X: \n', X)

    # This executes the GradientDescentSolver solver
    matRes = ctx.gradientDescentSolver(matF1, matF2, X)

    # Check the result
    Y = ctx.matZeros(r,c)
    matF1(matRes, Y)
    print('matRes: \n', matRes)
    print('Y: \n', Y)
    nrm = ctx.sqrt( Y[0]*Y[0] + Y[1]*Y[1]) # result is correct
    print('Norm: \n', nrm)
```

Example:

```
Public Sub matF1(x As dbl_mat_t, y As dbl_mat_t)
    Dim t1 As Double = 1 - x(0)
```

(continues on next page)

(continued from previous page)

```
    Dim t2 As Double = x(1) - x(0) * x(0)
    y(0) = t1 * t1 + 100 * t2 * t2
End Sub

Public Sub matF2(x As dbl_mat_t, y As dbl_mat_t)
    y(0) = -2 * (1 - x(0)) + 200 * (x(1) - x(0) * x(0)) * (-2 * x(0))
    y(1) = 200 * (x(1) - x(0) * x(0))
End Sub

Sub DemoConjugatedGradientDescentSolverDbl()
    Console.WriteLine("Hello DemoConjugatedGradientDescentSolverDbl() ")
    Dim X, Y As New dbl_mat_t()
    X.resize(2, 1)
    Y.resize(X.rows, 1)
    X(0) = 1
    X(1) = 2

    Dim OptLib As New ConjugatedGradientDescentSolverDbl(AddressOf matF1, AddressOf matF2, X)
    Dim matRes = OptLib.Solve()
    matRes.print("matRes: ", 15)
    matF1(matRes, Y)
    Y.print("Y = F(matRes): ", 15)

    Dim nrm = Math.Sqrt( Y(0)*Y(0) + Y(1)*Y(1))
    Console.WriteLine("Norm: {0}", nrm)
    Console.WriteLine("")
End Sub
```

This produces the following output:

```
Hello DemoConjugatedGradientDescentSolverDbl()
matRes:
    0.999964;
    0.999928;

Y = F(matRes):
    0.000000;
    0.000000;

Norm: 1.3055097726625E-09
```

CHAPTER

SIX

EIGEN: DENSE AND SPARSE MATRICES

The source code for the C# tests in Visual Studio is divided in 4 parts:

Part 1 contains the source code for test procedures which work for real and complex dense matrices, and which work for floating point and ball arithmetic. It can be found online in the `XlCalcNet` repository or in the corresponding local `XlCalcNet` folder in the file B06a_MatAll.cs.

Part 2 contains the source code for test procedures which work for real and complex dense matrices, but which work only for floating point arithmetic. It can be found online in the `XlCalcNet` repository or in the corresponding local `XlCalcNet` folder in the file B06b_MatFp.cs.

Part 3 contains the source code for test procedures which work only for real dense matrices, and only for floating point arithmetic. It can be found online in the `XlCalcNet` repository or in the corresponding local `XlCalcNet` folder in the file B06c_MatFpReal.cs.

Part 4 contains the source code for test procedures which work only for real and complex sparse matrices, and only for floating point arithmetic. It can be found online in the `XlCalcNet` repository or in the corresponding local `XlCalcNet` folder in the file B06d_SpMat.cs.

6.1 Creating scalars and matrices

6.1.1 Creating a matrix, and converting from compatible data types

`ctx.mat_t`(x)

Converts from a real scalar of type dreal

6.1.2 Creating a matrix of zeros

`ctx.mat_zeros`(n, m)

Creates a $n \times m$ matrix of the indicated type and sets all entries to zero.

```
>>> from xlcalcnet import *
>>> ctx.dps = 15; n = 4; m = 4
>>> matA = ctx.mat_zeros(n, m, eigen=True)
>>> matA.show("matA, mat_zeros(n, m) :")
matA, mat_zeros(n, m) :
 0,  0,  0,  0,
 0,  0,  0,  0,
 0,  0,  0,  0,
 0,  0,  0,  0,
```

6.1.3 Creating a matrix of ones

`ctx.mat_ones(`n, m`)`

Creates a $n \times m$ matrix of the indicated type and sets all entries to one.

```
>>> from xlcalcnet import *
>>> ctx.dps = 15; n = 4; m = 4
>>> matA = ctx.mat_ones(n, m)
>>> matA.show("matA, mat_ones(n, m) :")
matA, mat_ones(n, m) :
 1,  1,  1,  1,
 1,  1,  1,  1,
 1,  1,  1,  1,
 1,  1,  1,  1,
```

6.1.4 Creating an identity matrix

`ctx.mat_identity(`n, m`)`

Creates a $n \times m$ identity matrix of the indicated type.

```
>>> from xlcalcnet import *
>>> ctx.dps = 15; n = 4; m = 4
>>> matA = ctx.mat_identity(n, m)
>>> matA.show("matA, mat_identity(n, m) :")
matA, mat_identity(n, m) :
 1,  0,  0,  0,
 0,  1,  0,  0,
 0,  0,  1,  0,
 0,  0,  0,  1,
```

6.1.5 Creating a general random matrix

`ctx.mat_random(`n, m`)`

Creates a $n \times m$ matrix of the indicated type and sets all entries to random values.

```
>>> from xlcalcnet import *
>>> ctx.dps = 15; n = 4; m = 4
>>> matA = ctx.mat_random(n, m)
>>> matA.show("matA, mat_random(n, m) :")
matA, mat_random(n, m) :
 0.35029145176550,  0.17410809656056,  0.30399487289041,  0.14731284524064,
 0.89596240119633,  0.85894344920194,  0.014984588152715,  0.16589861751152,
 0.82284005249184,  0.71050141911069,  0.091402935880612,  0.98852504043703,
 0.74660481582080,  0.51353495895260,  0.36445204016236,  0.44569231238746,
```

6.1.6 Creating a symmetric random matrix

`ctx.mat_random_symmetric(`n`)`

Creates a $n \times n$ symmetric matrix of the indicated type and sets all entries to random values.

```
>>> from xlcalcnet import *
>>> ctx.dps = 15; n = 4; m = 4
>>> matA = ctx.mat_random_symmetric(n)
>>> matA.show("matA, mat_random_symmetric(n) :")
matA, mat_random_symmetric(n) :
 0.23816644795068,  0.53633228553118,  0.17514572588275,  0.43491927854244,
 0.53633228553118,  1.1423688467055,  1.2648091067232,  1.2148503067110,
 0.17514572588275,  1.2648091067232,  0.90157780693990,  1.1354411450545,
 0.43491927854244,  1.2148503067110,  1.1354411450545,  1.6052125614185,
```

6.1.7 Creating a self-adjoint random matrix

`ctx.`**`mat_random_selfadjoint`**(*n*, *complex=False*, *eigen=False*)

Creates a $n \times n$ selfadjoint matrix of the indicated type and sets all entries to random values.

```
>>> from xlcalcnet import *
>>> ctx.dps = 15; n = 4; m = 4
>>> matA = ctx.mat_random_sa(n)
>>> matA.show("matA, mat_random_sa(n) :")
matA, mat_random_sym(n) :
 0.23816644795068,  0.53633228553118,  0.17514572588275,  0.43491927854244,
 0.53633228553118,  1.1423688467055,  1.2648091067232,  1.2148503067110,
 0.17514572588275,  1.2648091067232,  0.90157780693990,  1.1354411450545,
 0.43491927854244,  1.2148503067110,  1.1354411450545,  1.6052125614185,
```

6.1.8 Creating a positive definite self-adjoint matrix

`ctx.`**`mat_random_selfadjoint_posdef`**(*n*, *complex=False*, *eigen=False*)

Creates a $n \times n$ positive definite random matrix of the indicated type.

```
>>> from xlcalcnet import *
>>> ctx.dps = 15; n = 4; m = 4
>>> matA = ctx.mat_random_sa_posdef(n)
>>> matA.show("matA, mat_random_sa_posdef(n)")
matA, mat_random_sa_posdef(n)
 1.6144949159812,  0.37328104299787,  0.64671931578811,  1.0725029543798,
 0.37328104299787,  0.23220359390837,  0.27432857744706,  0.35913470470614,
 0.64671931578811,  0.27432857744706,  0.55785829596540,  0.52838216584663,
 1.0725029543798,  0.35913470470614,  0.52838216584663,  1.4188647561723,
```

6.1.9 Creating a matrix with linearly increasing values

`ctx.`**`mat_fill_linear`**(*n*, *m*, *x*)

Creates a $n \times m$ matrix of the indicated type and sets all entries to increasing values.

```
>>> from xlcalcnet import *
>>> ctx.dps = 15; n = 4; m = 4
>>> matA = ctx.mat_linspace(n, m, x)
>>> matA.show("matA, mat_linspace(n, m, x) :")
matA, mat_linspace(n, m, x) :
 0,  0,  0,  0,
 0,  0,  0,  0,
 0,  0,  0,  0,
 0,  0,  0,  0,
```

6.2 Read-only properties: information about a matrix

6.2.1 Rows of a matrix

`ctx.`**`mat_rows`**`(`*matA*`)`

Returns the number of rows of the matrix. Writing `matA.rows` has the same effect.

```
>>> from xlcalcnet import *
>>> mpm.dps = 15;
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", "")
>>> print("A.rows: ", A.rows)
A.rows: 6
```

6.2.2 Columns of a matrix

`ctx.`**`mat_cols`**`(`*matA*`)`

Returns the number of columns of the matrix. Writing `matA.cols` has the same effect,

```
>>> from xlcalcnet import *
>>> mpm.dps = 15;
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", "")
>>> print("A.cols: ", A.cols)
A.cols: 4
```

6.2.3 Size of a matrix

`ctx.`**`mat_size`**`(`*matA*`)`

Returns the size of the matrix. Writing `matA.size` has the same effect.

```
>>> from xlcalcnet import *
>>> mpm.dps = 15;
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", "")
>>> print("A.size: ", A.size)
A.cols: 24
```

6.3 Accessing and setting parts of a matrix

6.3.1 Getting and setting a matrix coefficient

Individual coefficients of a matrix A are accessed using the `A[row,col]` syntax. Note that indexing starts at 0, so that the coefficient in the 4^{th} row and 2^{nd} column is accessed as `A[3,1]`. Examples:

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", ""); A.show("A")
A:
11,  12,  13,  14,
21,  22,  23,  24,
31,  32,  33,  34,
41,  42,  43,  44,
51,  52,  53,  54,
61,  62,  63,  64,

>>> # gets the coefficient in row number 3 and column number 1
>>> print("A[3,1]: ", A[3,1])
A[3,1]:  42

>>> # sets the coefficient in row number 1 and column number 2 to the value of 99.
>>> A[1,2] = 99; A.show("A")
matA:
11,  12,  13,  14,
21,  22,  99,  24,
31,  32,  33,  34,
41,  42,  43,  44,
51,  52,  53,  54,
61,  62,  63,  64,
```

6.3.2 Getting and setting a block

`ctx.`**`mat_get_block`**(*matA*, *i*, *j*, *p*, *q*)

Gets a block of the matrix, starting at row i and column j, with p row elements and q column elements. Writing `matA.get_Block(i, j, p, q)` has the same effect

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", ""); A.show("A")
A:
11,  12,  13,  14,
21,  22,  23,  24,
31,  32,  33,  34,
41,  42,  43,  44,
51,  52,  53,  54,
61,  62,  63,  64,

>>> # gets a block, beginning at A[1, 1], stretching to A[1+3, 1+2]
>>> b1 = A.block(1, 1, 3, 2); b1.show("b1")
b1:
22,  23,
32,  33,
42,  43,
```

`ctx.`**`mat_set_block`**(*matA*, *i*, *j*, *p*, *q*, *matB*)

Sets a block of the matrix to *matB*, starting at row i and column j, with p row elements and q column elements. Writing `matA.set_Block(i, j, p, q, matB)` has the same effect

```
>>> # continued from above
>>> # sets b1 into a block, beginning at A[0, 0], stretching to A[0+3, 0+2]
```

(continues on next page)

(continued from previous page)

```
>>> A.set_Block(0, 0, 3, 2, b1); ; A.show("A")
A:
22,  23,  13,  14,
32,  33,  23,  24,
42,  43,  33,  34,
41,  42,  43,  44,
51,  52,  53,  54,
61,  62,  63,  64,
```

6.3.3 Getting and setting a matrix row

ctx.mat_get_row(*matA*, *i*)

Gets the i^{th} row. Writing `matA.get_Row(i)` has the same effect

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", ""); A.show("A")
A:
11,  12,  13,  14,
21,  22,  23,  24,
31,  32,  33,  34,
41,  42,  43,  44,
51,  52,  53,  54,
61,  62,  63,  64,

>>> # gets row number 2 (i.e. the 3rd row from the top)
>>> r1 = A.row(2); r1.show("r1")
r1:
31,  32,  33,  34,
```

ctx.mat_set_row(*matA*, *i*, *matB*)

Sets the i^{th} row to *matB*. Writing `matA.set_Row(i, matB)` has the same effect

```
>>> # continued from above
>>> # sets the content of row number 5 to the content of row number 2
>>> A.set_Row(5, A.get_Row(2)); A.show("A")
A:
11,  12,  13,  14,
21,  22,  23,  24,
31,  32,  33,  34,
41,  42,  43,  44,
51,  52,  53,  54,
31,  32,  33,  34,
```

6.3.4 Getting and setting a matrix column

ctx.mat_get_col(*matA*, *j*)

Gets the j^{th} column. Writing `matA.get_Col(j)` has the same effect

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", ""); A.show("A")
A:
11,  12,  13,  14,
21,  22,  23,  24,
31,  32,  33,  34,
41,  42,  43,  44,
51,  52,  53,  54,
61,  62,  63,  64,
```

(continues on next page)

(continued from previous page)

```
>>> # gets column number 1 (i.e. the 2nd column from the left)
>>> c1 = A.col(1); c1.show("c1")
c1:
12,
22,
32,
42,
52,
62,
```

`ctx.`**`mat_set_col`**`(`*matA*, *j*, *matB*`)`

Sets the j^{th} column to *matB*. Writing `matA.set_Col(j, matB)` has the same effect

```
>>> # continued from above
>>> # sets the content of column number 3 to the content of column number 1
>>> A.set_Col(3, A.get_Col(1)); A.show("A")
A:
11,  12,  13,  12,
21,  22,  23,  22,
31,  32,  33,  32,
41,  42,  43,  42,
51,  52,  53,  52,
61,  62,  63,  62,
```

6.3.5 Getting and setting a diagonal

`ctx.`**`mat_get_diagonal`**`(`*matA*, *q=0*`)`

Gets the diagonal or a subdiagonal of the matrix. Writing `matA.get_Diagonal(q=0)` has the same effect.

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", ""); A.show("A")
A:
11,  12,  13,  14,
21,  22,  23,  24,
31,  32,  33,  34,
41,  42,  43,  44,
51,  52,  53,  54,
61,  62,  63,  64,

>>> # gets the first lower subdiagonal
>>> b1 = A.diagonal(-1); b1.show("b1")
b1 = A.diagonal(-1):
21,
32,
43,
54,
```

`ctx.`**`mat_set_diagonal`**`(`*matA*, *q*, *matB*`)`

Sets the diagonal or a subdiagonal of the matrix to *matB*. Writing `matA.set_Diagonal(q, matB)` has the same effect.

```
>>> # continued from above
>>> # sets the diagonal to the first lower subdiagonal
>>> A.set_Diagonal(0, b1); A.show("A")
A:
21,  12,  13,  14,
21,  32,  23,  24,
31,  32,  43,  34,
41,  42,  43,  54,
51,  52,  53,  54,
61,  62,  63,  64,
```

6.3.6 Getting and setting a triangular view

`ctx.`**`mat_get_triangular_view`**(*matA*, *view=1*)

Gets the triangular view of the matrix. Writing `matA.get_TriangularView(View = 1)` has the same effect.

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", ""); A.show("A")
A:
11,  12,  13,  14,
21,  22,  23,  24,
31,  32,  33,  34,
41,  42,  43,  44,
51,  52,  53,  54,
61,  62,  63,  64,

>>> # gets the first lower subdiagonal
>>> b1 = A.diagonal(-1); b1.show("b1")
b1 = A.diagonal(-1):
21,
32,
43,
54,
```

`ctx.`**`mat_set_triangular_view`**(*matA*, *view*, *matB*)

Sets the triangular view of the matrix to *matB*. Writing `matA.set_TriangularView(View, matB)` has the same effect.

```
>>> # continued from above
>>> # sets the diagonal to the first lower subdiagonal
>>> A.set_Diagonal(0, b1); A.show("A")
A:
21,  12,  13,  14,
21,  32,  23,  24,
31,  32,  43,  34,
41,  42,  43,  54,
51,  52,  53,  54,
61,  62,  63,  64,
```

6.4 Changing the shape of a matrix and/or the order of coefficients

6.4.1 Sorting a whole matrix

`ctx.mat_sort(`*matA*, *sort_order=0*, *sort_criterion=1*`)`

Returns a sorted version of the matrix, sorted according to SortOrder and SortCriterion.

Writing `matA.Sort(sort_order=0, sort_criterion=1)` has the same effect

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", ""); A.show("A")
A:
11, 12, 13, 14,
21, 22, 23, 24,
31, 32, 33, 34,
41, 42, 43, 44,
51, 52, 53, 54,
61, 62, 63, 64,

>>> # returns a copy of the whole matrix in ascending order (SortOrder=0)
>>> B = A.sorted(SortOrder=0); B.show("B")
B:
11, 23, 41, 53,
12, 24, 42, 54,
13, 31, 43, 61,
14, 32, 44, 62,
21, 33, 51, 63,
22, 34, 52, 64,

>>> # sorts the whole matrix in descending order (SortOrder=1)
>>> C = A.sorted(SortOrder=1); C.show("C")
C:
64, 52, 34, 22,
63, 51, 33, 21,
62, 44, 32, 14,
61, 43, 31, 13,
54, 42, 24, 12,
53, 41, 23, 11,
```

6.4.2 Sorting the rows of a matrix by a given column

`ctx.mat_sort_rows_by_col(`*matA*, *column_to_sort_by=0*, *sort_order=0*, *sort_criterion=1*`)`

Returns a sorted version of the matrix, sorted by column ColumnToSortBy, according to SortOrder and SortCriterion.

Writing `matA.SortRowsByCol(column_to_sort_by=0, sort_order=0, sort_criterion=1)` has the same effect

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", ""); A.show("A")
A:
11, 12, 13, 14,
21, 22, 23, 24,
31, 32, 33, 34,
41, 42, 43, 44,
51, 52, 53, 54,
61, 62, 63, 64,

>>> # sorts the whole matrix by column 0 in descending order (SortOrder=1)
>>> B = A.sorted_rows_by_col(ColumnToSortBy=0, SortOrder=1); B.show("B")
B:
61, 62, 63, 64,
51, 52, 53, 54,
```

(continues on next page)

(continued from previous page)

```
41, 42, 43, 44,
31, 32, 33, 34,
21, 22, 23, 24,
11, 12, 13, 14,

>>> # sorts the whole matrix in descending order (SortOrder=0)
>>> C = A.sorted_rows_by_col(ColumnToSortBy=0, SortOrder=0); C.show("C")
C:
11, 12, 13, 14,
21, 22, 23, 24,
31, 32, 33, 34,
41, 42, 43, 44,
51, 52, 53, 54,
61, 62, 63, 64,
```

6.4.3 Resize a matrix

`ctx.`**`mat_resize`**(*matA*, *r*, *c*)

Resizes the matrix inplace, setting values of coefficients to zero.

Writing `matA.Resize(r, c)` has the same effect

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", ""); A.show("A")
A:
11, 12, 13, 14,
21, 22, 23, 24,
31, 32, 33, 34,
41, 42, 43, 44,
51, 52, 53, 54,
61, 62, 63, 64,

>>> # resizes the matrix to 3 rows and 2 columns, setting values of coefficients to zero.
>>> A.resize(3,2); A.show("A")
A:
0, 0,
0, 0,
0, 0,
```

6.4.4 Resize a matrix like another matrix

`ctx.`**`mat_resize_like`**(*matA*, *matB*)

Resizes the matrix inplace, setting values of coefficients to zero.

Writing `matA.ResizeLike(matB)` has the same effect

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", ""); A.show("A")
A:
11, 12, 13, 14,
21, 22, 23, 24,
31, 32, 33, 34,
41, 42, 43, 44,
51, 52, 53, 54,
61, 62, 63, 64,

>>> # resizes the matrix to 3 rows and 2 columns, setting values of coefficients to zero.
>>> A.resize(3,2); A.show("A")
A:
```

(continues on next page)

(continued from previous page)

```
0, 0,
0, 0,
0, 0,
```

6.4.5 Conservatively resize a matrix

`ctx.`**`mat_conservative_resize`**`(`*matA*, *r*, *c*`)`

Resizes the matrix inplace, retaining values of existing coefficients.

Writing `matA.ConservativeResize(r, c)` has the same effect

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", ""); A.show("A")
A:
11, 12, 13, 14,
21, 22, 23, 24,
31, 32, 33, 34,
41, 42, 43, 44,
51, 52, 53, 54,
61, 62, 63, 64,

>>> # resizes the matrix to 3 rows and 6 columns, retaining values of existing coefficients.
>>> A.conservative_resize(3,6); A.show("A")
A:
11, 12, 13, 14,  0,  0,
21, 22, 23, 24,  0,  0,
31, 32, 33, 34,  0,  0,
```

6.4.6 Convert vector to diagonal matrix

`ctx.`**`mat_as_diagonal`**`(`*matA*`)`

Returns the first column vector of a matrix as a diagonal matrix.

Writing `matA.AsDiagonal()` has the same effect

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> # read the first column from the matrix
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", "").col(0); A.show("A")
A:
11,
21,
31,
41,
51,
61,

>>> # resizes the matrix to 3 rows and 6 columns, retaining values of existing coefficients.
>>> B = A.as_diagonal(); B.show("B")
B:
11,  0,  0,  0,  0,  0,
 0, 21,  0,  0,  0,  0,
 0,  0, 31,  0,  0,  0,
 0,  0,  0, 41,  0,  0,
 0,  0,  0,  0, 51,  0,
 0,  0,  0,  0,  0, 61,
```

6.4.7 Adjoint of a matrix

`ctx.`**`mat_adjoint`**`(`*matA*`)`

Returns the adjoint matrix of the matrix. Writing `matA.Adjoint()` has the same effect

```
>>> from xlcalcnet import *

>>> # example with a real matrix
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x6", ""); A.show("A")
A:
11, 12, 13, 14, 15, 16,
21, 22, 23, 24, 25, 26,
31, 32, 33, 34, 35, 36,
41, 42, 43, 44, 45, 46,
51, 52, 53, 54, 55, 56,
61, 62, 63, 64, 65, 66,

>>> # returns the adjoint matrix of a real matrix, i.e. the transpose
>>> B = A.adjoint(); B.show("B")
B:
11, 21, 31, 41, 51, 61,
12, 22, 32, 42, 52, 62,
13, 23, 33, 43, 53, 63,
14, 24, 34, 44, 54, 64,
15, 25, 35, 45, 55, 65,
16, 26, 36, 46, 56, 66,

>>> # example with a complex matrix
>>> ctx = mp14.dcf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecCplxTableA6x6", ""); A.show("A")
A:
11 + 31j, 12 + 32j, 13 + 33j, 14 + 34j, 15 + 35j, 16 + 36j,
21 + 41j, 22 + 42j, 23 + 43j, 24 + 44j, 25 + 45j, 26 + 46j,
31 + 51j, 32 + 52j, 33 + 53j, 34 + 54j, 35 + 55j, 36 + 56j,
41 + 61j, 42 + 62j, 43 + 63j, 44 + 64j, 45 + 65j, 46 + 66j,
51 + 71j, 52 + 72j, 53 + 73j, 54 + 74j, 55 + 75j, 56 + 76j,
61 + 81j, 62 + 82j, 63 + 83j, 64 + 84j, 65 + 85j, 66 + 86j,

>>> # returns the adjoint matrix of a complex matrix, i.e. the conjugate of the transpose
>>> B = A.adjoint(); B.show("B")
B:
11 + -31j, 21 + -41j, 31 + -51j, 41 + -61j, 51 + -71j, 61 + -81j,
12 + -32j, 22 + -42j, 32 + -52j, 42 + -62j, 52 + -72j, 62 + -82j,
13 + -33j, 23 + -43j, 33 + -53j, 43 + -63j, 53 + -73j, 63 + -83j,
14 + -34j, 24 + -44j, 34 + -54j, 44 + -64j, 54 + -74j, 64 + -84j,
15 + -35j, 25 + -45j, 35 + -55j, 45 + -65j, 55 + -75j, 65 + -85j,
16 + -36j, 26 + -46j, 36 + -56j, 46 + -66j, 56 + -76j, 66 + -86j,
```

6.4.8 Conjugate of a matrix

`ctx.`**`mat_conjugate`**`(`*matA*`)`

Returns the conjugate matrix of matrix matA. Writing `matA.Conjugate()` has the same effect

```
>>> from xlcalcnet import *

>>> # example with a real matrix
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x6", ""); A.show("A")
A:
11, 12, 13, 14, 15, 16,
```

(continues on next page)

(continued from previous page)

```
21, 22, 23, 24, 25, 26,
31, 32, 33, 34, 35, 36,
41, 42, 43, 44, 45, 46,
51, 52, 53, 54, 55, 56,
61, 62, 63, 64, 65, 66,

>>> # returns the conjugate matrix of a real matrix, i.e. the matrix itself
>>> B = A.conjugate(); B.show("B")
B:
11, 12, 13, 14, 15, 16,
21, 22, 23, 24, 25, 26,
31, 32, 33, 34, 35, 36,
41, 42, 43, 44, 45, 46,
51, 52, 53, 54, 55, 56,
61, 62, 63, 64, 65, 66,

>>> # example with a complex matrix
>>> ctx = mp14.dcf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecCplxTableA6x6", ""); A.show("A")
A:
11 + 31j, 12 + 32j, 13 + 33j, 14 + 34j, 15 + 35j, 16 + 36j,
21 + 41j, 22 + 42j, 23 + 43j, 24 + 44j, 25 + 45j, 26 + 46j,
31 + 51j, 32 + 52j, 33 + 53j, 34 + 54j, 35 + 55j, 36 + 56j,
41 + 61j, 42 + 62j, 43 + 63j, 44 + 64j, 45 + 65j, 46 + 66j,
51 + 71j, 52 + 72j, 53 + 73j, 54 + 74j, 55 + 75j, 56 + 76j,
61 + 81j, 62 + 82j, 63 + 83j, 64 + 84j, 65 + 85j, 66 + 86j,

>>> # returns the conjugate matrix of a complex matrix
>>> B = A.conjugate(); B.show("B")
B:
11 + -31j, 12 + -32j, 13 + -33j, 14 + -34j, 15 + -35j, 16 + -36j,
21 + -41j, 22 + -42j, 23 + -43j, 24 + -44j, 25 + -45j, 26 + -46j,
31 + -51j, 32 + -52j, 33 + -53j, 34 + -54j, 35 + -55j, 36 + -56j,
41 + -61j, 42 + -62j, 43 + -63j, 44 + -64j, 45 + -65j, 46 + -66j,
51 + -71j, 52 + -72j, 53 + -73j, 54 + -74j, 55 + -75j, 56 + -76j,
61 + -81j, 62 + -82j, 63 + -83j, 64 + -84j, 65 + -85j, 66 + -86j,
```

6.4.9 Transpose of a matrix

`ctx.`**`mat_transpose`**`(`*matA*`)`

Returns the transposed matrix of matrix matA. Writing `matA.Transpose()` has the same effect

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", ""); A.show("A")
A:
11, 12, 13, 14,
21, 22, 23, 24,
31, 32, 33, 34,
41, 42, 43, 44,
51, 52, 53, 54,
61, 62, 63, 64,

>>> # returns the transpose matrix of a real matrix
>>> B = A.transpose(); B.show("B")
B:
11, 21, 31, 41, 51, 61,
12, 22, 32, 42, 52, 62,
13, 23, 33, 43, 53, 63,
14, 24, 34, 44, 54, 64,
```

6.4.10 Full Reverse of a matrix

`ctx.mat_reverse_full(matA)`

Returns the full reverse of matrix matA. Writing `matA.ReverseFull()` has the same effect

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", ""); A.show("A")
A:
11, 12, 13, 14,
21, 22, 23, 24,
31, 32, 33, 34,
41, 42, 43, 44,
51, 52, 53, 54,
61, 62, 63, 64,

>>> # returns the full reverse  of the matrix
>>> B = A.reverse_full(); B.show("B")
B:
64, 63, 62, 61,
54, 53, 52, 51,
44, 43, 42, 41,
34, 33, 32, 31,
24, 23, 22, 21,
14, 13, 12, 11,
```

6.4.11 Row-wise Reverse of a matrix

`ctx.mat_reverse_row_wise(matA)`

Returns the row-wise reverse of matrix matA. Writing `matA.ReverseRowwise()` has the same effect

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", ""); A.show("A")
A:
11, 12, 13, 14,
21, 22, 23, 24,
31, 32, 33, 34,
41, 42, 43, 44,
51, 52, 53, 54,
61, 62, 63, 64,

>>> # returns the row-wise reverse of the matrix
>>> B = A.reverse_rowwise(); B.show("B")
14, 13, 12, 11,
24, 23, 22, 21,
34, 33, 32, 31,
44, 43, 42, 41,
54, 53, 52, 51,
64, 63, 62, 61,
```

6.4.12 Column-wise Reverse of a matrix

`ctx.mat_reverse_col_wise(matA)`

Returns the column-wise reverse of matrix matA. Writing `matA.ReverseColwise()` has the same effect

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", ""); A.show("A")
A:
11, 12, 13, 14,
21, 22, 23, 24,
```

(continues on next page)

(continued from previous page)

```
31, 32, 33, 34,
41, 42, 43, 44,
51, 52, 53, 54,
61, 62, 63, 64,

>>> # returns the column-wise reverse of the matrix
>>> B = A.reverse_colwise(); B.show("B")
B:
61, 62, 63, 64,
51, 52, 53, 54,
41, 42, 43, 44,
31, 32, 33, 34,
21, 22, 23, 24,
11, 12, 13, 14,
```

6.4.13 Full Replication of a matrix

`ctx.`**`mat_replicate_full`**`(`*matA*, *vertical*, *horizontal*`)`

Returns a full replication of matrix matA. Writing `matA.ReplicateFull(vertical, horizontal)` has the same effect

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", ""); A.show("A")
A:
11, 12, 13, 14,
21, 22, 23, 24,
31, 32, 33, 34,
41, 42, 43, 44,
51, 52, 53, 54,
61, 62, 63, 64,

>>> # returns a full replication (Vertical=2, Horizontal=3) of the matrix
>>> B = A.replicate_full(2, 3); B.show("B")
B:
11, 12, 13, 14, 11, 12, 13, 14, 11, 12, 13, 14,
21, 22, 23, 24, 21, 22, 23, 24, 21, 22, 23, 24,
31, 32, 33, 34, 31, 32, 33, 34, 31, 32, 33, 34,
41, 42, 43, 44, 41, 42, 43, 44, 41, 42, 43, 44,
51, 52, 53, 54, 51, 52, 53, 54, 51, 52, 53, 54,
61, 62, 63, 64, 61, 62, 63, 64, 61, 62, 63, 64,
11, 12, 13, 14, 11, 12, 13, 14, 11, 12, 13, 14,
21, 22, 23, 24, 21, 22, 23, 24, 21, 22, 23, 24,
31, 32, 33, 34, 31, 32, 33, 34, 31, 32, 33, 34,
41, 42, 43, 44, 41, 42, 43, 44, 41, 42, 43, 44,
51, 52, 53, 54, 51, 52, 53, 54, 51, 52, 53, 54,
61, 62, 63, 64, 61, 62, 63, 64, 61, 62, 63, 64,
```

6.4.14 Row-wise Replication of a matrix

`ctx.`**`mat_replicate_row_wise`**`(`*matA*, *horizontal*`)`

Returns a row-wise replication of matrix matA. Writing `matA.ReplicateRowwise(horizontal)` has the same effect

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", ""); A.show("A")
A:
11, 12, 13, 14,
21, 22, 23, 24,
31, 32, 33, 34,
41, 42, 43, 44,
51, 52, 53, 54,
```

(continues on next page)

(continued from previous page)

```
61, 62, 63, 64,

>>> # returns a row-wise replication (Horizontal=4) of the matrix
>>> B = A.replicate_rowwise(4); B.show("B")
B:
11, 12, 13, 14, 11, 12, 13, 14, 11, 12, 13, 14, 11, 12, 13, 14,
21, 22, 23, 24, 21, 22, 23, 24, 21, 22, 23, 24, 21, 22, 23, 24,
31, 32, 33, 34, 31, 32, 33, 34, 31, 32, 33, 34, 31, 32, 33, 34,
41, 42, 43, 44, 41, 42, 43, 44, 41, 42, 43, 44, 41, 42, 43, 44,
51, 52, 53, 54, 51, 52, 53, 54, 51, 52, 53, 54, 51, 52, 53, 54,
61, 62, 63, 64, 61, 62, 63, 64, 61, 62, 63, 64, 61, 62, 63, 64,
```

6.4.15 Column-wise Replication of a matrix

`ctx.`**`mat_replicate_col_wise`**`(`*matA*, *vertical*`)`

Returns a column-wise replication of matrix matA. Writing `matA.ReplicateColwise(vertical)` has the same effect

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x4", ""); A.show("A")
A:
11, 12, 13, 14,
21, 22, 23, 24,
31, 32, 33, 34,
41, 42, 43, 44,
51, 52, 53, 54,
61, 62, 63, 64,

>>> # returns a column-wise replication (Vertical=2) of the matrix
>>> B = A.replicate_colwise(2); B.show("B")
B:
11, 12, 13, 14,
21, 22, 23, 24,
31, 32, 33, 34,
41, 42, 43, 44,
51, 52, 53, 54,
61, 62, 63, 64,
11, 12, 13, 14,
21, 22, 23, 24,
31, 32, 33, 34,
41, 42, 43, 44,
51, 52, 53, 54,
61, 62, 63, 64,
```

6.4.16 Horizontal concatenation of two matrices

`ctx.`**`mat_concat_horizontal`**`(`*matA*, *matB*`)`

Returns the horizontal concatenation of matrix matA with matrix matB. Writing `matA.ConcatHorizontal(matB)` has the same effect

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x6", ""); A.show("A")
A:
11, 12, 13, 14, 15, 16,
21, 22, 23, 24, 25, 26,
31, 32, 33, 34, 35, 36,
41, 42, 43, 44, 45, 46,
51, 52, 53, 54, 55, 56,
61, 62, 63, 64, 65, 66,
```

(continues on next page)

(continued from previous page)

```
>>> B = ctx.read_from_sqlite(mp14.dbpath(), "DecTableB6x6", ""); B.show("B")
B:
911, 912, 913, 914, 915, 916,
921, 922, 923, 924, 925, 926,
931, 932, 933, 934, 935, 936,
941, 942, 943, 944, 945, 946,
951, 952, 953, 954, 955, 956,
961, 962, 963, 964, 965, 966,

>>> # returns a column-wise replication (Vertical=2) of the matrix
>>> C = A.concat_horizontal(B); C.show("C")
C:
 11,  12,  13,  14,  15,  16, 911, 912, 913, 914, 915, 916,
 21,  22,  23,  24,  25,  26, 921, 922, 923, 924, 925, 926,
 31,  32,  33,  34,  35,  36, 931, 932, 933, 934, 935, 936,
 41,  42,  43,  44,  45,  46, 941, 942, 943, 944, 945, 946,
 51,  52,  53,  54,  55,  56, 951, 952, 953, 954, 955, 956,
 61,  62,  63,  64,  65,  66, 961, 962, 963, 964, 965, 966,
```

6.4.17 Vertical concatenation of two matrices

`ctx.`**`mat_concat_vertical`**`(`*matA*, *matB*`)`

Returns the vertical concatenation of matrix matA with matrix matB.

Writing `matA.ConcatVertical(matB)` has the same effect

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x6", ""); A.show("A")
A:
11, 12, 13, 14, 15, 16,
21, 22, 23, 24, 25, 26,
31, 32, 33, 34, 35, 36,
41, 42, 43, 44, 45, 46,
51, 52, 53, 54, 55, 56,
61, 62, 63, 64, 65, 66,

>>> B = ctx.read_from_sqlite(mp14.dbpath(), "DecTableB6x6", ""); B.show("B")
B:
911, 912, 913, 914, 915, 916,
921, 922, 923, 924, 925, 926,
931, 932, 933, 934, 935, 936,
941, 942, 943, 944, 945, 946,
951, 952, 953, 954, 955, 956,
961, 962, 963, 964, 965, 966,

>>> # returns a column-wise replication (Vertical=2) of the matrix
>>> C = A.concat_vertical(B); C.show("C")
C:
 11,  12,  13,  14,  15,  16,
 21,  22,  23,  24,  25,  26,
 31,  32,  33,  34,  35,  36,
 41,  42,  43,  44,  45,  46,
 51,  52,  53,  54,  55,  56,
 61,  62,  63,  64,  65,  66,
911, 912, 913, 914, 915, 916,
921, 922, 923, 924, 925, 926,
931, 932, 933, 934, 935, 936,
941, 942, 943, 944, 945, 946,
951, 952, 953, 954, 955, 956,
961, 962, 963, 964, 965, 966,
```

6.5 Basic arithmetic operations

6.5.1 Matrix deep copy (unary plus)

Returns the matrix multiplied with +1. This results in a deep copy of the matrix.

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x6", ""); A.show("A")
A:
11, 12, 13, 14, 15, 16,
21, 22, 23, 24, 25, 26,
31, 32, 33, 34, 35, 36,
41, 42, 43, 44, 45, 46,
51, 52, 53, 54, 55, 56,
61, 62, 63, 64, 65, 66,
>>> B = A
>>> C = +A
>>> A[1,1] = 99
>>> B.show("B")
B:
11, 12, 13, 14, 15, 16,
21, 99, 23, 24, 25, 26,
31, 32, 33, 34, 35, 36,
41, 42, 43, 44, 45, 46,
51, 52, 53, 54, 55, 56,
61, 62, 63, 64, 65, 66,
>>> C.show("C")
C:
11, 12, 13, 14, 15, 16,
21, 22, 23, 24, 25, 26,
31, 32, 33, 34, 35, 36,
41, 42, 43, 44, 45, 46,
51, 52, 53, 54, 55, 56,
61, 62, 63, 64, 65, 66,
```

6.5.2 Matrix negation (unary minus)

Returns the matrix multiplied with -1.

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x6", ""); A.show("A")
A:
11, 12, 13, 14, 15, 16,
21, 22, 23, 24, 25, 26,
31, 32, 33, 34, 35, 36,
41, 42, 43, 44, 45, 46,
51, 52, 53, 54, 55, 56,
61, 62, 63, 64, 65, 66,
>>> B = -A
>>> B.show("B")
B:
-11, -12, -13, -14, -15, -16,
-21, -99, -23, -24, -25, -26,
-31, -32, -33, -34, -35, -36,
-41, -42, -43, -44, -45, -46,
-51, -52, -53, -54, -55, -56,
-61, -62, -63, -64, -65, -66,
```

6.5.3 General matrix addition

Returns the sum of matrix matA and matrix matB. matA and matB need to be of the same type and need to have the same dimensions. The returned matrix is of the same type as matA. Special rules apply for mixing real and complex matrices.

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x6", ""); A.show("A")
A:
11, 12, 13, 14, 15, 16,
21, 22, 23, 24, 25, 26,
31, 32, 33, 34, 35, 36,
41, 42, 43, 44, 45, 46,
51, 52, 53, 54, 55, 56,
61, 62, 63, 64, 65, 66,
>>> B = ctx.read_from_sqlite(mp14.dbpath(), "DecTableB6x6", ""); B.show("B")
B:
911, 912, 913, 914, 915, 916,
921, 922, 923, 924, 925, 926,
931, 932, 933, 934, 935, 936,
941, 942, 943, 944, 945, 946,
951, 952, 953, 954, 955, 956,
961, 962, 963, 964, 965, 966,
>>> C = A + B; C.show("C")
C:
 922,  924,  926,  928,  930,  932,
 942,  944,  946,  948,  950,  952,
 962,  964,  966,  968,  970,  972,
 982,  984,  986,  988,  990,  992,
1002, 1004, 1006, 1008, 1010, 1012,
1022, 1024, 1026, 1028, 1030, 1032,
```

6.5.4 Matrix addition of a vector as diagonal matrix

Returns the matrix product of matrix matA and matrix matB. matA and matB need to be of the same type and need to have compatible dimensions. The returned matrix is of the same type as matA. Special rules apply for mixing real and complex matrices.

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> # read the first column from the matrix
>>> d = ctx.read_from_sqlite(mp14.dbpath(), "DecTableB6x6", "").col(0); d.show("d")
d:
911,
921,
931,
941,
951,
961,

>>> # creates a square matrix with the coefficents of d1 on the diagonal.
>>> D = d.as_diagonal(); D.show("D")
D:
911,   0,   0,   0,   0,   0,
  0, 921,   0,   0,   0,   0,
  0,   0, 931,   0,   0,   0,
  0,   0,   0, 941,   0,   0,
  0,   0,   0,   0, 951,   0,
  0,   0,   0,   0,   0, 961,

>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x6", ""); A.show("A")
A:
11, 12, 13, 14, 15, 16,
21, 22, 23, 24, 25, 26,
31, 32, 33, 34, 35, 36,
41, 42, 43, 44, 45, 46,
```

(continues on next page)

(continued from previous page)

```
51, 52, 53, 54, 55, 56,
61, 62, 63, 64, 65, 66,

>>> C = A + D; C.show("C")    # same as D + A()
C:
 922,   12,   13,   14,   15,   16,
  21,  943,   23,   24,   25,   26,
  31,   32,  964,   34,   35,   36,
  41,   42,   43,  985,   45,   46,
  51,   52,   53,   54, 1006,   56,
  61,   62,   63,   64,   65, 1027,

>>> C = A + d.diagonal_view(); C.show("C")    # same as d.diagonal_view + A()
C:
 922,   12,   13,   14,   15,   16,

```

6.5.5 Matrix: addition of a scalar

Returns the sum of matrix matA and scalar b, applied to each coefficient of matA. The coefficients of matA and b need to be of the same type. The returned matrix is of the same type as matA. Special rules apply for mixing real and complex matrices and real and complex scalars.

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x6", ""); A.show("A")
A:
11, 12, 13, 14, 15, 16,
21, 22, 23, 24, 25, 26,
31, 32, 33, 34, 35, 36,
41, 42, 43, 44, 45, 46,
51, 52, 53, 54, 55, 56,
61, 62, 63, 64, 65, 66,
>>> B = A + 15;  B.show("B")
B:
26, 27, 28, 29, 30, 31,
36, 37, 38, 39, 40, 41,
46, 47, 48, 49, 50, 51,

66, 67, 68, 69, 70, 71,
76, 77, 78, 79, 80, 81,
```

6.5.6 General matrix subtraction

Returns the difference of matrix matA and matrix matB. matA and matB need to be of the same type and need to have the same dimensions. The returned matrix is of the same type as matA. Special rules apply for mixing real and complex matrices.

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x6", ""); A.show("A")
A:
11, 12, 13, 14, 15, 16,
21, 22, 23, 24, 25, 26,
31, 32, 33, 34, 35, 36,

46, 47, 48, 49, 50, 51,
```

6.5.8 General matrix multiplication (“gemm”)

See also Eigen [240].

In its general form, matrix multiplication takes the form $\boldsymbol{C} = \boldsymbol{AB}$, where $\boldsymbol{A}$ is a m-by-k matrix, $\boldsymbol{B}$ is a k-by-n matrix, and $\boldsymbol{C}$ is a m-by-n matrix. Also, the transposed or adjoined matrices of $\boldsymbol{A}$ and/or $\boldsymbol{B}$ are often directly used.

In the general form, no information regarding special properties of $\boldsymbol{A}$ and/or $\boldsymbol{B}$ is used. If such information is available, specialized forms of multiplication are often signifantly faster:

- if $\boldsymbol{A}$ or $\boldsymbol{B}$ is a triangular or diagonal matrix, or
- if the multiplication with the inverse of a square, triangular or diagonal matrix is desired, or
- if $\boldsymbol{B}$ is the transpose of $\boldsymbol{A}$.

In the canonical FORTRAN package BLAS, the BLAS Level 3 function $?\mathrm{gemm}$ and the BLAS Level 2 function $?\mathrm{gemv}$ handle this

kind of expression, with the scalars α β and the indicator variables TransA and TransB as additional parameters:

$$?\text{gemm} = \begin{cases} \alpha\boldsymbol{AB} + \beta\boldsymbol{C}, & \text{for TransA = 'N', TransB = 'N',} \\ \alpha\boldsymbol{AB}^T + \beta\boldsymbol{C}, & \text{for TransA = 'N', TransB = 'T',} \\ \alpha\boldsymbol{AB}^H + \beta\boldsymbol{C}, & \text{for TransA = 'N', TransB = 'C',} \\ \alpha\boldsymbol{A}^T\boldsymbol{B} + \beta\boldsymbol{C}, & \text{for TransA = 'T', TransB = 'N',} \\ \alpha\boldsymbol{A}^T\boldsymbol{B}^T + \beta\boldsymbol{C}, & \text{for TransA = 'T', TransB = 'T',} \\ \alpha\boldsymbol{A}^T\boldsymbol{B}^H + \beta\boldsymbol{C}, & \text{for TransA = 'T', TransB = 'C',} \\ \alpha\boldsymbol{A}^H\boldsymbol{B} + \beta\boldsymbol{C}, & \text{for TransA = 'C', TransB = 'N',} \\ \alpha\boldsymbol{A}^H\boldsymbol{B}^T + \beta\boldsymbol{C}, & \text{for TransA = 'C', TransB = 'T',} \\ \alpha\boldsymbol{A}^H\boldsymbol{B}^H + \beta\boldsymbol{C}, & \text{for TransA = 'C', TransB = 'C',} \end{cases}$$

$$?\text{gemv} = \begin{cases} \alpha\boldsymbol{Ax} + \beta\boldsymbol{y}, & \text{for TransA = 'N',} \\ \alpha\boldsymbol{A}^T\boldsymbol{x} + \beta\boldsymbol{y}, & \text{for TransA = 'T',} \\ \alpha\boldsymbol{A}^H\boldsymbol{x} + \beta\boldsymbol{y}, & \text{for TransA = 'C'.} \end{cases}$$

We use the `transpose()` and `adjoint()` properties to compute these expressions efficiently. Here are some examples with real matrices:

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf()
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableA6x6", ""); A.show("A")
A:
11, 12, 13, 14, 15, 16,

```

6.5.9 Arithmetic comparisons with a scalar or a matrix

`ctx.mat_count`(*matA*, *query*, *comparator*)

Returns the number of coefficients in matrix matA which are greater than the corresponding coefficients in matrix matB.

Writing `matA.count(query, comparator)` has the same effect.

Queries are: ">, <, >=, <=, !=, ==", For complex matrices, the absolute values are compared

```
>>> from xlcalcnet import *
>>> mpm.dps = 40;
>>> A = mp14.xrf().read_from_sqlite(mp14.dbpath(), "MpfrTableA4x4", "")
>>> B = mp14.xrf().read_from_sqlite(mp14.dbpath(), "MpfrTableB4x4", "")
```

6.6 Descriptive Statistics

6.6.1 Partial Sum

`ctx.mat_sum`(*mat*, *partialmode*)

Calculates the PartialSum. Writing `matA.sum(partialmode)` has the same effect.

Here partialmode is set as follows: 1 for full matrix calculation, 2 for rowwise calculation, 3 for columnwise calculation.

See also: Eigen [237].

6.6.2 Partial Product

`ctx.mat_prod`(*matA*, *partialmode*)

Calculates the PartialProd. Writing `matA.prod(partialmode)` has the same effect.

Here partialmode is set as follows: 1 for full matrix calculation, 2 for rowwise calculation, 3 for columnwise calculation.

See also: Eigen [237].

6.6.3 Partial Arithmetic Mean

`ctx.mat_mean`(*matA*, *partialmode*)

Calculates the PartialMean. Writing `matA.mean(partialmode)` has the same effect.

Here partialmode is set as follows: 1 for full matrix calculation, 2 for rowwise calculation, 3 for columnwise calculation.

See also: Eigen [237].

6.6.4 Partial Minimal Coefficient

`ctx.mat_min_coeff`(*matA*, *partialmode*)

Calculates the PartialMinCoeff. Writing `matA.min_coeff(partialmode)` has the same effect.

Here partialmode is set as follows: 1 for full matrix calculation, 2 for rowwise calculation, 3 for columnwise calculation.

See also: Eigen [237].

6.6.5 Partial Maximal Coefficient

`ctx.mat_max_coeff`(*matA*, *partialmode*)

Calculates the PartialMaxCoeff. Writing `matA.max_coeff(partialmode)` has the same effect.

Here partialmode is set as follows: 1 for full matrix calculation, 2 for rowwise calculation, 3 for columnwise calculation.

See also: Eigen [237].

6.6.6 Trace

`ctx.mat_trace`(*matA*)

Returns the trace of the matrix A. Writing `matA.Trace()` has the same effect.

See also: Eigen [237], Wikipedia [1395].

6.6.7 Partial Squared Norm

`ctx.mat_squared_norm(`*matA*, *partialmode*`)`

Calculates the PartialSquaredNorm. Writing `matA.PartialSquaredNorm(partialmode)` has the same effect.

Here partialmode is set as follows: 1 for full matrix calculation, 2 for rowwise calculation, 3 for columnwise calculation.

See also: Eigen [237].

6.6.8 Partial Norm

`ctx.mat_norm(`*matA*, *partialmode*`)`

Calculates the PartialNorm. Writing `matA.PartialNorm(partialmode)` has the same effect.

Here partialmode is set as follows: 1 for full matrix calculation, 2 for rowwise calculation, 3 for columnwise calculation.

See also: Eigen [237].

6.6.9 Partial Stable Norm

`ctx.mat_stable_norm(`*matA*, *partialmode*`)`

Calculates the PartialStableNorm. Writing `matA.PartialStableNorm(partialmode)` has the same effect.

Here partialmode is set as follows: 1 for full matrix calculation, 2 for rowwise calculation, 3 for columnwise calculation.

See also: Eigen [237].

6.6.10 Covariance matrix

`ctx.mat_covariance(`*matA*`)`

Calculates the covariance matrix. Writing `matA.Covariance()` has the same effect.

See also: Wikipedia [1391], Wikipedia [1371].

6.6.11 Correlation matrix

`ctx.mat_correlation(`*matA*`)`

Calculates the correlation matrix. Writing `matA.Correlation_mat()` has the same effect.

See also: Wikipedia [1369].

6.7 Standard decompositions and linear solving

6.7.1 Cholesky Decomposition with Pivoting

`ctx.mat_ldlt`(*matA*, *Query*, *matB*)

Returns the Cholesky decomposition of the symmetric matrix *matA* $= A = A = P^T LDLP$, with partial pivoting.

Writing `matA.LDLT(Query, matB)` has the same effect

See also Eigen [230], Wikipedia [1427], Wikipedia [1432].

Parameters:

Query
Required. A string specifying which items of the result section should be computed.

B
Optional. A general n-by-m matrix of the same type as A. You need to specify B only if you want to solve the linear equation $AX = B$

Results:

info
An integer indicating whether the decomposition was successful (=0) or not(=1).

ispos
An integer indicating whether the matrix A is semidefinit positve (=0) or not(=1).

isneg
An integer indicating whether the matrix A is semidefinit negative (=0) or not(=1).

det
A scalar of a return type matching A. The determinant of A.

rcond
A scalar of the same return type as det. The condition number of A.

X
A general matrix of the same type and dimension as B. The solution to $AX = B$.

Inv
A square matrix of the same type and dimension as A. The inverse of A, A^{-1}.

P
A square matrix of the same type and dimension as A. The permutation matrix P in the decomposition $A = P^T LDLP$.

L
A square matrix of the same type and dimension as A, containing the matrix L in the decomposition $A = P^T LDLP$.

D
A square matrix of the same type and dimension as A, containing the matrix D in the decomposition $A = P^T LDLP$.

Perform a robust Cholesky decomposition of a positive semidefinite or negative semidefinite matrix such that $A = P^T LDLP$, where P is a permutation matrix, L is lower triangular with a unit diagonal and D is a diagonal matrix. The decomposition uses pivoting to ensure stability, so that L will have zeros in the bottom right rank(A) - n submatrix. Avoiding the square root on D also stabilizes the computation. Remember that Cholesky decompositions are not rank-revealing. Also, do not use a Cholesky decomposition to determine whether a system of equations has a solution

rankUpdate: Update the LDLT decomposition: given $A = LDLT$, efficiently compute the decomposition of $A+\sigma ww^T$. Parameters: w a vector to be incorporated into the decomposition. σ a scalar, +1 for updates and -1 for "downdates", which correspond to removing previously-added column vectors. Optional; default value is +1.

solve: Returns a solution x of $Ax = b$ using the current decomposition of A. This function also supports in-place solves using the syntax x = decompositionObject.solve(x) .

This method just tries to find as good a solution as possible. If you want to check whether a solution exists or if it is accurate, just call this function to get a result and then compute the error of this result, or use MatrixBase::isApprox() directly, for instance like this:

bool a solution exists = (A*result).isApprox(b, precision);

This method avoids dividing by zero, so that the non-existence of a solution does not by itself mean that you will get inf or nan values.

More precisely, this method solves $Ax = b$ using the decomposition $A = P^T LDL * P$ by solving the systems

$P^T y1 = b, LY2 = y1, Dy3 = y2, L * y4 = y3$ and $Px = y4$ in succession.

If the matrix A is singular, then D will also be singular (all the other matrices are invertible). In that case, the least-square solution of $Dy3 = y2$ is computed. This does not mean that this function computes the least-square solution of $Ax = b$ if A is singular.

6.7.1.1 Example for a real symmetric matrix

```
>>> from xlcalcnet import *

6.7.2 LU Decomposition with partial Pivoting

`ctx.mat_partial_piv_lu`(*matA*, *Query*, *matB*)

Returns the LU decomposition of the general square matrix *matA* $= A = PLU$, with partial pivoting.

Writing `matA.PartialPivLU(Query, matB)` has the same effect

See also Eigen [232], Wikipedia [1414], Wikipedia [1432].

Parameters:

Query
Required. A string specifying which items of the result section should be computed.

B
Optional. A general n-by-m matrix of the same type as A. You need to specify B only if you want to solve the linear equation $AX = B$

Results:

det
A scalar of a return type matching A. The determinant of A.

rcond
A scalar of the same return type as det. The condition number of A.

X
A general matrix of the same type and dimension as B. The solution to $AX = B$.

Inv
A square matrix of the same type and dimension as A. The inverse of A, A^{-1}.

P
A square matrix of the same type and dimension as A. The permutation matrix P in the decomposition $A = PLU$.

LU
A square matrix of the same type and dimension as A, containing the matrices L and U in the decomposition $A = PLU$.

This class represents a LU decomposition of a square invertible matrix, with partial pivoting: the matrix A is decomposed as A = PLU where L is unit-lower-triangular, U is upper-triangular, and P is a permutation matrix.

Typically, partial pivoting LU decomposition is only considered numerically stable for square invertible matrices. Thus LAPACK's dgesv and dgesvx require the matrix to be square and invertible. The present class does the same. It will assert that the matrix is square, but it won't (actually it cannot) check that the matrix is invertible: it is your task to check that you only use this decomposition on invertible matrices. The guaranteed safe alternative, working for all matrices, is the full pivoting LU decomposition, provided by class FullPivLU.

This is not a rank-revealing LU decomposition. Many features are intentionally absent from this class, such as rank computation. If you need these features, use class FullPivLU.

This LU decomposition is suitable to invert invertible matrices. It is what MatrixBase::inverse() uses in the general case. On the other hand, it is not suitable to determine whether a given matrix is invertible. The data of the LU decomposition can be directly accessed through the methods matrixLU(), permutationP().

6.7.2.1 Example for a real general square matrix (Python)

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf(); mp14.setdps(35); mp14.setshowdps(3)
>>> A = ctx.read_from_sqlite(mp14.dbpath(), "DecTableRandomA6x6", ""); A.show("A")

>>> # This needs to be a square matrix
```

6.7.3 LU Decomposition with full Pivoting

`ctx.mat_full_piv_lu`(*matA*, *Query*, *matB*)

Returns the LU decomposition of the general square matrix *matA* $= A = PLUQ$, with full pivoting. See also Eigen [224], Wikipedia [1428], Wikipedia [1432].

Writing `matA.FullPivLU(Query, matB)` has the same effect

Parameters:

Query
Required. A string specifying which items of the result section should be computed.

B
Optional. A general n-by-m matrix of the same type as A. You need to specify B only if you want to solve the linear equation $AX = B$

Results:

isinjective
An boolean value indicating whether A is injective.

isinvertible
An boolean value indicating whether A is invertible.

issurjective
An boolean value indicating whether A is surjective.

rank
An integer. The rank of A.

det
A scalar of a return type matching A. The determinant of A.

rcond
A scalar of the same return type as det. The condition number of A.

X
A general matrix of the same type and dimension as B. The solution to $AX = B$.

Inv
A square matrix of the same type and dimension as A. The inverse of A, A^{-1}.

P
A square matrix of the same type and dimension as A. The permutation matrix P in the decomposition $A = PLUQ$.

Q
A square matrix of the same type and dimension as A. The permutation matrix Q in the decomposition $A = PLUQ$.

LU
A square matrix of the same type and dimension as A, containing the matrices L and U in the decomposition $A = PLUQ$.

This class represents a LU decomposition of any matrix, with complete pivoting: the matrix A is decomposed as $A = PLUQ$ where L is unit-lower-triangular, U is upper-triangular, and P and Q are permutation matrices. This is a rank-revealing LU decomposition. The eigenvalues (diagonal coefficients) of U are sorted in such a way that any zeros are at the end.

This decomposition provides the generic approach to solving systems of linear equations, computing the rank, invertibility, inverse, kernel, and determinant. This LU decomposition is very stable and well tested with large matrices. However there are use cases where the SVD decomposition is inherently more stable and/or flexible. For example, when computing the kernel of a matrix, working with the SVD allows to select the smallest singular values of the matrix, something that the LU decomposition doesn't see.

6.7.3.1 Example for a real matrix

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf(); mp14.setdps(35); mp14.setshowdps(3)

6.7.4 Cholesky Decomposition without Pivoting

`ctx.mat_llt`(*matA*, *Query*, *matB*)

Returns the Cholesky decomposition of the symmetric matrix *matA* $= A = LL^T = U^TU$, without pivoting.

Writing `matA.LLT(Query, matB)` has the same effect

See also Eigen [231], Wikipedia [1402], Wikipedia [1432].

Parameters:

Query
Required. A string specifying which items of the result section should be computed.

B
Optional. A general n-by-m matrix of the same type as A. You need to specify B only if you want to solve the linear equation $AX = B$

Results:

det
A scalar of a return type matching A. The determinant of A.

rcond
A scalar of the same return type as det. The condition number of A.

X
A general matrix of the same type and dimension as B. The solution to $AX = B$.

Inv
A square matrix of the same type and dimension as A. The inverse of A, A^{-1}.

L
A square matrix of the same type and dimension as A, containing the matrix L in the decomposition $A = LL^T = U^TU$.

U
A square matrix of the same type and dimension as A, containing the matrix U in the decomposition $A = LL^T = U^TU$.

These functions perform a LL^T Cholesky decomposition of a symmetric, positive definite matrix A such that $A = LL^T = U^TU$, where L is lower triangular. While the Cholesky decomposition is particularly useful to solve selfadjoint problems like $D^TDx = b$, for that purpose, we recommend the Cholesky decomposition without square root which is more stable and even faster. Nevertheless, this standard Cholesky decomposition remains useful in many other situations like generalised eigen problems with hermitian matrices. Remember that Cholesky decompositions are not rank-revealing. This LL^T decomposition is only stable on positive definite matrices, use LDL^T instead for the semidefinite case. Also, do not use a Cholesky decomposition to determine whether a system of equations has a solution.

6.7.4.1 Example for a real symmetric matrix

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf(); mp14.setdps(35); mp14.setshowdps(3)

6.7.5 QR Decomposition without Pivoting

`ctx.mat_householder_qr`(*matA*, *Query*, *matB*)

Returns the QR decomposition of the symmetric matrix *matA* $= A = QR$, without pivoting.

Writing `mat.HouseholderQR(Query, matB)` has the same effect

See also Eigen [228], Wikipedia [1436], Wikipedia [1432].

Parameters:

Query
Required. A string specifying which items of the result section should be computed.

B
Optional. A general n-by-m matrix of the same type as A. You need to specify B only if you want to solve the linear equation $AX = B$

Results:

signdet
A scalar of a return type matching A. The sign of the determinant of A.

absdet
A scalar of a return type matching A. The absolute value of the determinant of A.

logabsdet
A scalar of a return type matching A. The logarithm of the absolute value of the determinant of A.

X
A general matrix of the same type and dimension as B. The solution to $AX = B$.

Inv
A square matrix of the same type and dimension as A. The inverse of A, A^{-1}.

QR
A square matrix of the same type and dimension as A, containing the matrices Q and R in the decomposition $A = QR$.

This class performs a QR decomposition of a matrix A into matrices Q and R such that $A = QR$ by using Householder transformations. Here, Q a unitary matrix and R an upper triangular matrix. The result is stored in a compact way compatible with LAPACK. Note that no pivoting is performed.

This is not a rankrevealing decomposition. If you want that feature, use FullPivHouseholderQR or ColPivHouseholderQR instead.

This Householder QR decomposition is faster, but less numerically stable and less feature-rich than FullPivHouseholderQR or ColPivHouseholderQR

6.7.5.1 Example for a real general square matrix (Python)

```
>>> from xlcalcnet import *
>>> ctx = mp14.drf(); mp14.setdps(35); mp14.setshowdps(3)
